In any quart bottle of milk on which the cream has risen, the top nine ounces will contain about three times as much fat as the whole milk contained, and the top fourteen or fifteen ounces about twice as much, as will

*Read before the Medical Society of the State of New York at its ninety-fifth annual meeting, held in Albany on Tuesday, Wednesday, and Thursday, January 29, 30, and 31, 1901.

seen from the following assays made by the Babcock method, of poor, medium, and rich milks, as delivered in bottles to families:

	Fat, Per Cent.	Fat, Per Cent.	Fat, Per Cent.
Whole milk.	3.1	4.2	4.8
Top 6 ounces.	13.4	19.0	23.0
“ 7 “	11.6	16.4	19.8
“ 8 “	10.2	14.1	17.3
“ 9 “	9.2	12.6	15.5
“ 10 “	8.4	11.4	13.9
“ 11 “	7.7	10.4	12.7
“ 12 “	7.1	9.6	11.7
“ 13 “	6.6	9.0	10.8
“ 14 “	6.2	8.3	10.0
“ 15 “	5.8	7.8	9.4
“ 16 “	5.5	7.4	9.0
Skim milk.	0.7	0.6	0.4

These proportions are affected very little by uneven separation of cream. It is unusual to find a quart of bottled milk in which there is much less than 0.5 per cent. of fat or more than 1.5 per cent. of fat in the skim milk.

The table below shows a calculation of the percentage of fat in different top milks that can be taken from poor, medium, and rich whole milks, when the skim milk contains 0.5, 1, and 1.5 per cent. of fat.

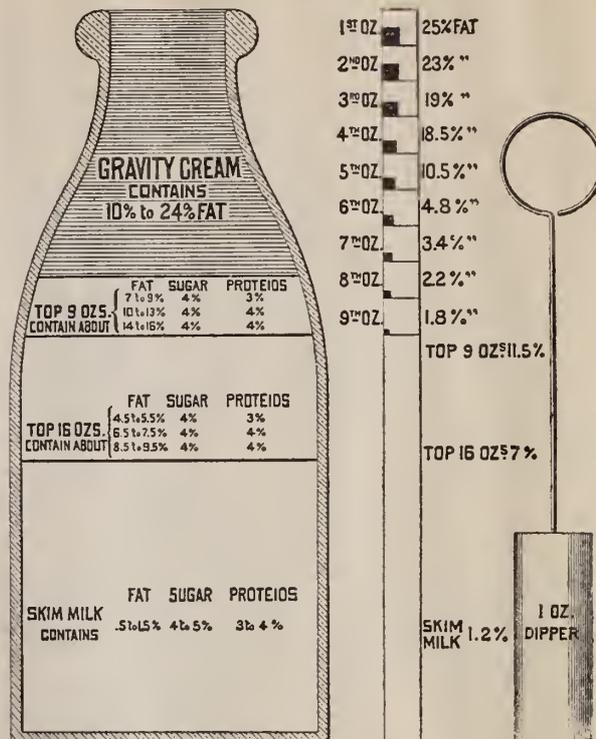

It is generally accepted that in nine tenths of all mixed, or market, milks the quantities of fat and proteids are nearly equal, and that in weak creams there is but slight falling off in proteids from what are found in

WHOLE MILK CONTAINS

the whole milk, so the top nine or ten ounces of a quart of milk after the cream has risen will contain about three times as much fat as proteids, and the top fifteen or sixteen ounces about twice as much fat as proteids. In these top milks we have about the ratios between fat and proteids found in woman's milk, but the quantities are too great for the infant's digestion and must be reduced by diluting.

The whole situation is shown in the illustration.

Because chemical analyses of milks show little of their differences, chemists divide milks into two classes: 1. Milks that form *soft, flaky curds* with rennet, which include woman's, mare's, and ass's milk. 2. Milks that form *hard, solid curds* with rennet, which include cow's and goat's milk.

There is a great difference between rennet curds and sour-milk curds. The natural souring of milk, or the addition of acids to milk, simply throws the casein out of solution. Upon neutralizing the acid, the casein goes

back into solution again. Rennet, which is an enzyme found in the stomachs of all animals, produces a chemical change in casein, clotting it very much as blood clots. In cow's milk, a clotted jelly or curd is first formed, which rapidly shrinks, squeezing out a clear, watery liquid known as whey, which contains the sugar and soluble albumin of the milk and another soluble proteid known as "whey proteid," which is not lactalbumin, but which is the result of the action of the rennet on the casein.

As the shrinking proceeds, a membrane forms on the curds which helps to hold the fat and bacteria of the milk in the meshes of the curd. If the curd is broken up before this membrane forms, the particles will readily unite again.

These curds are a breeding ground for putrefactive bacteria, and cheese made from milk containing much stable filth, which supplies putrefactive bacteria, develops a strong odor of decomposition.

Some authors call the rennet curds of milk *casein*, and the original proteid *caseinogen*; others call the curds *tyrein*, and the original proteid *casein*.

A food, to be easily digested, must be readily reduced to a finely divided state like that of chyme. It is not how quickly a certain kind of food may be peptonized, but how easily it can leave the stomach, that decides its suitability in cases of weak digestion.

Digestion of food is brought about by the action of digestive enzymes. Not much is known about these enzymes, except that to digest food they must come in contact with it, that they will digest practically unlimited quantities of food under proper conditions, and that their secretion is provoked, if not wholly controlled, by the absorption of nutriment. The digestive juices, which contain these enzymes, prevent putrefactive changes in food.

As during digestion there is an increased consumption of proteids and carbohydrates, it is significant that about one third of the proteids of woman's milk can be absorbed with very little digestive effort, and that the remaining two thirds form a soft, flaky curd which can easily leave the stomach; also, that the sugar of woman's milk is different from the sugar of cow's milk.

About one fifth of the proteids of cow's milk is in a soluble form, similar to albumin, and can be absorbed with little digestive effort, but when the milk is diluted for the infant, the *quantity* of this easily absorbed proteid becomes exceedingly small and the proteid that the infant actually gets has a tendency to contract and harden, exposing a small surface to the action of the digestive juices and forming a well-protected culture medium for putrefactive bacteria that may be present in the milk.

Diluting cow's milk with water does not prevent the formation of solid, leathery curds; diluting with a wheat, barley, rice, or oatmeal gruel, in which the starch has preferably been digested or dextrinized, breaks up the curds. The cellulose, or cell wall, of the cereal, which is left after the starch has been digested or put in soluble form, holds the curds apart and prevents their shrinking. Furthermore, digested starch is one of the forms of nutriment that are known to be rapidly absorbed and to promote the secretion of the digestive juices.

Here are two specimens of modified milk, one representing medium cow's milk diluted four times with water, and the other the same milk diluted four times with digested or dextrinized wheat-flour gruel; both were curded with rennet. All of the specimen prepared with digested wheat-flour gruel will go through a sieve having nine hundred meshes to the square inch; little or none of the specimen prepared with water will pass through the same sieve.

To prepare this dextrinized gruel, two heaping table-spoonsful of wheat or barley flour are beaten to a smooth, thin paste with a little cold water. A quart of boiling

water is added and the gruel is boiled for about fifteen minutes. It is then cooled by setting the dish of gruel in cold water until the gruel is cool enough to be tasted, when a preparation of diastase is added. I have previously shown how an aqueous solution of diastase can be prepared at home by soaking malted barley grains in cold water, or there is obtainable a preparation of diastase known as *cereo*, made for this purpose; the thick malt extracts also contain diastase; the gruel is stirred and kept warm until it becomes thin and watery. The little particles of cellulose are then seen floating in the thin gruel.

In preparing the infant's food, follow these steps:

Have the milk bottled at the dairy and set on ice or in cold water to prevent bacterial growth and promote the separation of cream.

Dip off the top nine ounces or top sixteen ounces into a pitcher or bowl, and set aside the milk bottle to avoid confusion. It is much better to dip off the top milk than to siphon off the bottom milk. When a siphon is used, all the sediment in the milk goes into the infant's food, as it collects in the edges and at the bottom of the bottle. The siphon is also difficult to manipulate.

Prepare the gruel.

Dilute the top milk with the digested gruel and add sugar.

The food for a young infant should contain from one eighth to one third of the nine ounces of top milk.

The food for an older infant should contain from one sixth to two thirds of the sixteen ounces of top milk.

Diluting the top milk reduces the sugar in the food too much; additional sugar equal to from one twenty-fifth to one twentieth of the ounces of food brings this ingredient up to the proper quantity. Either granulated or milk sugar may be used. One dipperful of granulated sugar, or a dipperful and a half of milk sugar, equals one ounce. An even tablespoonful of granulated sugar equals half an ounce.

During hot weather, when the milk or food cannot be kept below 60° F., it will have to be pasteurized.

The digestion of each child must be made the standard.

By beginning with weak mixtures and gradually increasing the strength of the food, little difficulty will be encountered. When there is vomiting of food, the digested gruel may be fed temporarily, and a top milk poorer in fat used for making up the next feeding.

Each additional ounce removed from the milk bottle reduces the fat in the top milk from 0.5 to 1 per cent., which will make the reduction in the infant's food from one eighth to one third of 1 per cent., depending on the dilution. Proteids are varied by increasing or decreasing the dilution.

Fine adjustments of percentages or very low proteids are not needed by this method, for the cause of most digestive disturbances of infancy that require

change of percentages is the neglect to alter the physical character of the proteids of cow's milk.

No matter whether milk is rich or poor, practically the same percentages will be attained by this method; rich milk will be diluted more, poor milk less; that is all. No other method has been devised for home use that gives such accurate percentage results, or is as easy of application, as this method has proved to be.

A CLINICAL REPORT ON THE USE OF CHLORETONE AS A HYPNOTIC.

By A. A. STEVENS, M. D.,

PHILADELPHIA,

LECTURER ON PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA, PHYSICIAN TO THE EPISCOPAL AND ST. AGNES'S HOSPITAL.

CHLORETONE, or trichlor tertiary butyl alcohol, is a compound formed by the addition of caustic potash to equal weights of chloroform and acetone. Its valuable properties as a local anæsthetic and hypnotic were first brought to the attention of the profession in an article by Houghton and Aldrich, which appeared in the *Journal of the American Medical Association* for September 13, 1899. It appears as a white crystalline powder, having a camphoraceous odor and taste. It is sparingly soluble in cold water, but freely soluble in chloroform, ether, and strong alcohol. The usual dose as a hypnotic is from fifteen to twenty grains. It may be conveniently administered in the form of powders or compressed tablets.

During the past six months I have used chloretone in at least fifty cases in which sleeplessness was an important symptom. The best results were obtained in the insomnia which was unassociated with organic disease. Thus, in five cases of neurasthenia in which the drug was used a single dose of twenty grains at bedtime would generally produce refreshing sleep lasting from six to eight hours. In two of these cases the action of chloretone was especially noteworthy, since opium gave rise to excitement, and chloralamide and trional, while not followed by any untoward effects, failed to secure the desired result. In a case of acute melancholia with delusions of persecution, it also acted favorably.

In chronic heart disease, when the symptoms were not very severe, chloretone was often useful, but when anxiety, restlessness, dyspnoea, and præcordial distress were prominent symptoms, morphine hypodermically was a far more satisfactory remedy. In chronic nephritis it generally gave good results. In one case, that of a middle-aged man, with uræmic delirium, it was given every night for two weeks, and rarely failed to quiet the patient and to secure a restful sleep of at least three or four hours' duration.

In several cases of pneumonia with moderate fever, but without delirium, the results were unsatisfactory. An hour's sleep would sometimes follow the exhibition

of from 10 to 20 grains of chloretone, but often there would be no effect, or at most only a slight lessening of the restlessness.

In delirium tremens the drug was, as a rule, much less efficacious than paraldehyde, bromides, or hyoscine. In one man, however, in whom the delirium developed while he was under treatment for a compound fracture of the leg, chloretone acted very well. Twenty-grain doses always exerted a quieting effect, and would generally induce sleep lasting from five to six hours. On one occasion a dose of twenty-five grains had but little effect during the night of its administration, but the patient slept soundly all of the next day and the following night.

In phthisis the results, as is generally the case with somnificants in this disease, were very variable. In the majority of cases, however, it did not succeed. No untoward symptoms were observed, but sleep rarely followed its use. The failures, it is worthy of note, were chiefly in the cases with well-marked febrile symptoms. Cough and night-sweats did not appear to be influenced in any way by the drug.

In typhoid fever, during the height of the disease, chloretone did not prove to be a very reliable hypnotic. Its value was far below that of opium, chloralamide, and sulphonal. During convalescence, however, from typhoid fever and other acute diseases the results were all that could be desired.

In a case of tic douloureux two doses of chloretone of twenty grains each failed to afford the slightest relief. In other painful affections, such as articular rheumatism, pleurisy, and neuritis, the remedy generally failed to induce sleep. In one case, however, of pelvic peritonitis its action was superior to that of opium, chloralamide, or sulphonal.

In view of the well-marked anæsthetic properties of chloretone when applied to a denuded surface, it was thought that the drug would be especially valuable in organic diseases of the stomach, both by relieving pain and promoting sleep; but in several cases of gastric cancer and in one case of gastric ulcer, the results were very disappointing and morphine had to be substituted.

In one case of morphinomania in which the daily dose of the narcotic had not exceeded two grains, chloretone was employed with satisfactory results; in two other cases, however, in which the habit was more pronounced the remedy proved useless.

In no case did chloretone give rise to any untoward symptoms or to unpleasant after-effects, except in a few instances in which it caused a feeling of drowsiness on the day following its administration. Nausea and vomiting were never excited by it. As a hypnotic its action is prompt, sleep usually following in from half an hour to two hours after its administration. The drug seems to have but little influence on the circulation; even in cases of chronic heart disease there was no evidence of a depressant action. It often loses its power to induce sleep when used continuously, and in this respect it is

probably inferior to opium, chloral, sulphonal, or paraldehyde. In several cases in which it had been very efficacious at first it completely failed after it had been exhibited for three or four successive nights. In insomnia due to pain it is of little value, and in insomnia due to extreme mental excitement it is inferior to hyoscyne and paraldehyde. Repeated observations established the fact that it seldom was successful in the presence of fever, at least when the temperature was above 102° or 103° F. In ordinary doses it appears to be a perfectly safe drug. I have never given more than thirty grains at a single dose, but Houghton and Aldrich state that as high as sixty grains have been given at one time without producing any untoward symptoms, and Donald (*Therapeutic Gazette*, January 15, 1900) cites the case of a person addicted to morphine who, in a period of little more than forty-eight hours, took 192 grains of chloretone, and in consequence slept almost continuously for nearly six days, when he awoke none the worse for his experience.

In conclusion, it would appear that we have in chloretone a safe hypnotic of moderate power, which rarely gives rise to unpleasant after-effects, but of which a toleration is quite rapidly acquired; which is especially adapted for use in cases of insomnia unattended with pain, high fever, or pronounced nervous excitement.

Therapeutical Notes.

Chloral Liniment for Lumbago.—Lafond-Grellety (*Therapeutische Monatshefte*, 1901, page 54) recommends energetic rubbing of the affected portion for ten minutes with a mixture of chloral hydrate and olive oil. The chloral hydrate must be dissolved in a little water before adding it to the oil. Masse recommends a mixture of 60 parts each of lime water and oil with 30 parts of chloral hydrate.

Vasoliment is, according to the *American Druggist* for December 24, 1900, the title given by Bedall, a German pharmacist, to a liquid vehicle for the external application of medicaments, which is composed of 50 parts of oleic acid, 50 parts of spirit of ammonia, and 100 parts of liquid petrolatum. On heating the ingredients together, a clear liquid results, in which ichthyol (with a small residue), iodine, creosote, menthol, tar, etc., may be dissolved in almost any desired strength.

For Acne Vulgaris.—Captain W. D. Sutherland, I. M. S. (*Indian Medical Gazette*, November, 1900), gives the following notes from Dr. Karl Herxheimer's clinic at Frankfurt. The parts are daily smeared with this salve:

℞ Tannic acid. 5 parts;
Precipitated sulphur. 10 "
Vaseline. 85 "

M. Ft. unguent.

When the irritation caused by this treatment becomes very marked, the treatment is suspended for a couple of days or so, and is then resumed.

Or the parts may be painted daily with this lotion:

℞ Sulphur liniment. 6 parts;
Glycerin. 1 part.

M.

The sulphur liniment of the German *Pharmacopœia* has the following formula:

℞ Precipitated sulphur. 15 grains;
Almond water, of each. 2½ drachms;
Glycerin,
Lime water. ½ an ounce.

M.

Another treatment is:

For half an hour, once daily, for five days, the parts are covered with Herxheimer's salve:

℞ Resublimated resorcin, } of each. . . . 20 parts;
Zinc oxide, }
Powdered starch, }
Vaseline. 40 parts.

M. Ft. unguent.

This is then removed with a spatula and oil rag, and at night the parts are thickly smeared with Wilson's salve:

℞ Zinc oxide. 60 grains;
Simple benzoin tincture. 1 drachm;
Lard or lanoline. 1 ounce.

M. Ft. unguent. To be applied nightly for five nights.

This is to be left on all night and washed off with soap and hot water in the morning. After five days' treatment with the two salves, the result is noted, and nothing done for at least ten days.

Nerium Oleander in Heart Disease.—For several years Mendelssohn, of Berlin (*Semaine médicale*, 1900, No. 29; *Indian Medical Gazette*, January), has been studying the action of this plant in cases of heart disorder, and finds that for commencing failure of compensation, chronic myocarditis, and fatty degeneration of the heart muscle, such as is frequently met with in old alcoholics, the following infusion is useful:

℞ Leaves of nerium oleander. . . . 7 to 15 grains;
Infuse in boiling water. 8 ounces.

Of this the patient takes a dessertspoonful every two or three hours.

In most cases one finds—provided that the heart muscle is not profoundly affected—that the pulse becomes slower and more regular, the palpitations rapidly disappear, diuresis is increased, and the peri-articular infiltrations—the heralds of anasarca—become less marked and finally vanish.

Where, however, the heart muscle is profoundly affected these satisfactory results cannot be obtained, unless digitalis is given.

Treatment of Arsenical Neuritis.—Dr. T. J. Paton writes to the *British Medical Journal* for February 9th with reference to the treatment of chronic neuritis as produced by the late arsenical epidemic. He has had a few cases, and in all of them has succeeded in curing it with citrate of iron and ammonium and liquor strychninæ, B. P. In one very bad case he had to increase the dose of the strychnine solution to seven minims, with a successful result. In the acute stage of catarrh, carbonate of ammonium was most successful.

NEW YORK, SATURDAY, FEBRUARY 23, 1901.

THE ARMY MEDICAL SERVICE AS A CAREER.

FROM time to time we have published official information for medical men who might be desirous of entering the medical corps of the army. In this issue we print the latest circular on the subject that has been issued by the surgeon-general. It will be seen that, owing to the recent enlargement of the regular army, there is an unusual number of original vacancies in the ranks of the assistant surgeons, namely, a hundred and twenty-nine. We learn that the prescribed age limit of candidates will be rigidly adhered to, so that it will be useless for those who are more than twenty-nine years of age to apply, unless they have had previous service as mentioned in the circular. We learn also that the requirement of hospital experience, or its equivalent in private practice, will be strictly insisted upon. Hospital work as an undergraduate will not be regarded as fulfilling this requirement; experience as a physician after graduation is what is meant. Two years of private practice will be considered as the equivalent of a year's hospital experience. The requirements and the examinations are rigid, as they always have been, and as they ought to be. Nobody but a well-equipped man, sound in body and mind, can enter the medical corps of the army; consequently it is a picked body, one to which it is a high honor to belong, and we predict that the government will find no difficulty in filling the unusual number of vacancies with the flower of our young medical graduates by the examinations that are soon to be held in Washington and in San Francisco.

Apart from quite exceptional aids to a successful career in medicine, we know of nothing more promising to the young physician than a life connection with the army. It is no more honorable than a like career in the navy, but it seems to us more attractive and richer in opportunities for active professional work. In the first

place, there is the great advantage of the course in the Army Medical School, affording both additional education and an opportunity to learn much of the ways of the nation's capital. When the young medical officer comes to see actual service, it is almost sure in times of peace to be at a permanent military post or in connection with some department headquarters in a large city, for the old-time bugbear of "the plains," we take it, has become little more than a tradition. A military post, however exacting it may be for the line officers, is not by any means an uninteresting or uncongenial place for the medical officer. The society is of the best, and his professional duties, attendance upon the officers and men and their wives and children, together with sanitary inspection, and precision as to matters of record and report, are quite in line with what would occupy the mind of a busy civil practitioner in a community utterly free from paupers and tricksters and dominated by men and women of the highest type. Rarely, indeed, in civil life is such a community to be found.

All things considered, it must be admitted, we think, that the medical officer's remuneration, although none too large, is quite the equivalent of what the average well-trained medical graduate has to look forward to. Moreover, the provision for his old age, if not overabundant, is still such as to insure him against want. The army surgeon is not likely to become a man of wealth. Perhaps we may go further and say that the odds are greatly against his saving even a moderate competence, for he is almost of necessity a good, generous soul, either naturally or by force of association, giving freely for the purposes of entertainment. But he is not tormented with constantly having to take thought for the morrow.

Even in our new possessions, far from home as all of them but Puerto Rico are, the service will soon cease to be unattractive. The Hawaiian and Philippine Islands, and perhaps Guam, too, are doubtless destined soon to be largely peopled by Americans, and at the numerous permanent military posts that will have to be kept up in them army life will speedily come to be the pleasant life that it now is at the older posts. As he rises in rank, moreover, the medical officer of the army has, if he is active and ambitious, a reasonable prospect of serving at West Point, in the Army Medical Museum, in the Library of the Surgeon-general's office, or as a professor in the Army Medical School. Surely a man does not hide his light under a bushel when he enters the medical corps of the United States Army.

FANATICISM AND LAWLESSNESS.

AN incident that happened recently in Chicago may well lead those good people of fanatical tendencies who are not yet wholly unbalanced to pause and ask themselves what is the logical outcome of their two very objectionable methods for the suppression of such things as they consider evils to the community, viz., that of violence and that of undue restrictive legislation.

A certain Mrs. Carrie Nation has recently gained considerable notoriety in consequence of her crusade of violence against the liquor sellers. Her *modus operandi* has been now put into action by another set of fanatics, the faith healers. We learn that a well-organized body of middle-aged and well-dressed women, disciples of the faith-healing cult, recently made a crusade of violence, similar to that of Mrs. Nation, against the drug stores of Chicago, and not only destroyed the drugs, demolishing the "traffic of the devil," as they termed the necessities of the healing art, but even in some instances inflicted personal violence on the druggist himself.

It is true that in Kansas the traffic in liquor is illegal, and, while no civilized community can afford to tolerate the assumption of violent enforcement of the law at the hands of unauthorized individuals, there is, nevertheless, this difference between the two cases, that so long as Mrs. Nation confined her operations to the saloons of Kansas, her illegal acts were directed against what was in itself a breach of the law, while those of the Chicago fanatics were directed against that which is sanctioned by law in every State and has the moral and intellectual support of the overwhelming majority in every community. But Mrs. Nation has proposed to carry her measures into localities where liquor traffic is not a breach of the law, and, in fact, we understand, has in more than one instance already done so, and there is no doubt that her supporters hold her justified in so doing.

Now, if Mrs. Nation's belief and that of her supporters, that because in their eyes the liquor traffic is a work of the devil she is justified in using violence to suppress it, is tenable and worthy of commendation, it surely follows that the crusade against druggists and drugs (nay, why not against doctors also?) calls equally for justification and commendation.

It is undoubtedly the case that among the many fanatical adherents of prohibition in regard to liquor there are numbers who thankfully avail themselves in injury or disease of the services of the medical profession and its subsidiary arts, and who are firmly at one with the vast majority of mankind of all ages and places

in regarding the healing art, however imperfect, as being a most beneficent institution and one worthy of honor and support.

We would advise any such person to ask himself how he would feel if, having a dearly loved one racked with pain, or possibly lying at the point of death, and waiting anxiously for the precious medicine to still the racking agony, or to fight the grim oppressor as he attacked the loved one's life at its last intrenchment, the messenger should return with the news that every drug store had been wrecked, and even the medicine he was bringing destroyed by a band of people acting on the honest conviction that medicine was the traffic of the devil; or if, for the same reason, the surgeon summoned by him to the relief of a serious accident should be forcibly detained?

Surely he would consider it an act of atrocious and unbearable tyranny. Surely he would be none the more inclined tamely to submit to such an invasion of his rights because he felt that these fanatics were honest in their conviction that medicine and the medical art were bad for him, and that, as one of the Chicago body is reported to have said, "all the ills of human kind can be cured by prayer."

Only one degree less pernicious than the method of violence is the increasingly frequent resort to restrictive legislation to check the abuse of a thing by altogether forbidding its use. This process is all of a piece with the principle of religious persecution and intolerance. The prohibitionist is convinced that the use of alcohol, or tobacco, or what not, is bad for the individual and for the community, and, not content with himself abstaining from their use, he would compel all others, whatever their opinion on the subject, to abstain also. But was not that exactly the standpoint of the mediæval religious bigot? Satisfied of his possession of the "true faith," he was not content to follow its precepts himself, but decided that, not only in the interests of the individual, but in those of the community also, all others should be legally forced into line.

People talk of the ages of religious intolerance and persecution as things of the past. Intolerance of all kinds is as rampant to-day as ever it was. The only difference is that methods of violence and brutality, which were then common, are no longer generally approved in any respect, and the warring of opinions shares equally with other things in this immunity. But it seems that there is a growing tendency on the part of many to revert to them, and Mrs. Nation's hatchet and the drug-

destroyers' canes look perilously like the thin end of the wedge inserted in the cleft made by undue restrictive legislation. Restrictive legislation aimed against the invasion by the individual of the rights of other individuals or of the community at large, is one thing, and is very necessary; but exercised with the purpose of imposing the will of one faction on the actions of another, not in self-defense, but out of paternal solicitude to compel the other against his will, into "the better way," is tyranny. And it is equally tyranny whether it be the imposition of the will of one upon fifty thousand or of fifty thousand upon one.

THE BACTERIOLOGICAL THERAPEUTICS OF CONSTIPATION.

THE treatment of habitual constipation is a well-worn subject, but it is one that will amply repay constant consideration, so common is the ailment and so far-reaching in its effects on the organism. Certain recent observations by Roos, of Friburg (*Münchener medizinische Wochenschrift*, October 23d, 1900; *Indépendance médicale*, January 9th), seem to be novel in one respect, namely, that they have reference to the employment of micro-organisms in correcting intestinal torpor. He remarks that there are many facts to lead us to suppose that the *Bacterium coli commune* has an influence on peristaltic action, and it occurred to him to study this supposed action of the microbe by making cultures from specimens obtained from persons whose intestinal action was free and introducing them into the intestine of constipated persons, whether *per os* or *per anum* is not stated. He experimented on himself and on several young physicians, five out of seven of whom were constipated. Three of the five were immediately relieved, and the amelioration lasted for a fortnight. He then tried the method on two patients, both women. One of them was relieved, but the other felt no effect. While, therefore, the author regards the action of the bacterium as indisputable, he thinks that further trials are necessary before one can pronounce upon the practical utility of its employment.

Pursuing his line of investigation, Roos thought that he could count upon the *Bacillus acidi lactici* as another harmless microbe that would probably serve his purpose. He accordingly made agar-agar cultures of this bacillus and inclosed them in gelatin capsules. In this form it was taken by five physicians. In four of them there occurred increased peristaltic action, with some tenesmus, and at the outset a great deal of flatulence, but the fæcal

evacuations were hardly modified. Kephir had little effect, and gave rise to colicky pains. A solution of lactic acid was always effective, but its action was too transitory.

At last Roos tried yeast, a material that of late has come into varied use in therapeutics. He declares that he was surprised at the great success of his trials. He dried the yeast at a temperature of 86° F., and thus obtained a clear gray powder, which he gave in doses of eight grains two or three times a day, in the form of compressed tablets. Out of twenty patients, sixteen were so benefited that their evacuations were easy and copious, and in most of them the appetite was increased. The action of the yeast lasted for a considerable length of time after its administration was discontinued. It did not seem to be due to fermentation, for yeast with its germs killed by exposure for ten hours to a heat of 212° F. proved unexpectedly efficacious, acting like fresh yeast, but without giving rise to pain or flatulence.

THE HAVANA CONGRESS.

IT is much to be regretted that the attendance at the recent Third Pan-American Medical Congress, held in Havana, was not so large as had been expected, especially from the United States; also that many gentlemen from whom papers had been looked for failed to send their communications. We learn that the next meeting is to be held in Buenos Aires. To insure its success, the energetic men who in the past have exerted themselves in the interest of the congress will doubtless work with still greater activity.

A PROGRESSIVE SCANDINAVIAN JOURNAL.

THE *Nordiskt medicinskt Arkiv*, published in Stockholm, has for many years been one of the leading medical journals of the world. Its value has been much enhanced to those who do not read the language in which it is printed by the French abstracts of its original articles given in each number. It is now to be enlarged and published in two parts, a medical and a surgical, under the editorial charge of Dr. Axel Key; moreover, its entire contents will be translated into German, English, or French, as a rule. Its usefulness cannot fail to be largely increased.

HOW THE SUPPRESSION OF THE ARMY CANTEEN WORKS.

IT is working, and it is working promptly. Less than a mile from Fort Monroe there is a little village named Phœbus. The canteen was closed last week, and a weekly newspaper published in Phœbus is already exulting in the beneficence of the legislation that caused

it to be closed; many applications, it says, have been filed for licenses to open new saloons. The liquor traffic will flourish in Phœbus, and what does Phœbus care for what happens to the soldiers?

PRECEPT AND EXAMPLE.

A NEW JERSEY school principal took occasion recently at a teachers' meeting to attack the use of short skirts by women teachers and that of tobacco by the men. The first was inconsistent, in this luminous-minded person's eyes, with dignity; and as regarded the last, he could not see how male teachers could teach the evils of the use of tobacco when they used it themselves. The compulsory teaching of a distorted faddism under the guise of physiology is surely infliction enough without one's being obliged to live up to it. As to the use of the short skirt, there are few reforms of recent days more practical and salutary, even were it true that some trifling loss of "dignity" attended it. We commend to the professor's attention, however, a thoughtful perusal of Havelock Ellis's chapter on the Evolution of Modesty for enlightenment on this subject.

THE YALE MEDICAL SCHOOL'S PROSPECTIVE NEW CLINICAL BUILDING.

THE *Yale Alumni Weekly* for February 13th rightly sets forth the value of the projected new clinical building to the Medical School of Yale University. It is estimated that it will be finished in less than a year. It is to be a large building situated opposite the New Haven General Hospital. The school has always been creditable, and of late years it has shown itself very progressive.

THE ARCH-CHRISTIAN SCIENTIST'S GRACIOUSNESS.

MRS. EDDY, the founder of so-called Christian Science, is at least to be credited with moderate concessions to the demands of an unalleviated average environment. She is reported to have said that she has always believed that her disciples should be law-abiding. If the law demands an individual to submit to vaccination, she recommends that he obey the law "and then appeal to the Gospel to save him from any bad effects." She would also have her followers report contagious disease to the proper authorities when the law so requires.

GALACTOCELE IN THE MALE.

AMONG the curiosities of surgery must be included a case reported by Kirmisson (*Bulletins et mémoires de la Société de chirurgie*, xxv, p. 707; *Centralblatt für chirurgie*, December 29th). It was that of a boy, thirteen years old, who, two months before, had received a blow on the left breast. There was a roundish, freely movable, painless tumor as large as a small mandarin orange, and the nipple was retracted. On puncture, about six drachms of pure milk was evacuated.

News Items.

Society Meetings for the Coming Week:

- MONDAY, February 25th: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.
- TUESDAY, February 26th: New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Virginia, Academy of Medicine and Surgery.
- WEDNESDAY, February 27th: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society.
- THURSDAY, February 28th: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopædic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.
- FRIDAY, March 1st: Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.
- SATURDAY, March 2d: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending February 16, 1901:

DISEASES.	Week end'g Feb. 9.		Week end'g Feb. 16.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	27	9	20	11
Scarlet Fever.....	369	30	404	24
Cerebro-spinal meningitis.	0	0	0	0
Measles.....	145	5	159	7
Diphtheria and croup.....	260	40	296	50
Small-pox.....	17	6	25	6
Tuberculosis.....	282	165	280	189

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from February 2 to February 16, 1901:

- GANDY, CHARLES M., Captain and Assistant Surgeon, is detailed as an additional member of the general court-martial at Fort Slocum, N. Y.
- MCCULLOCH, CHAMPE C., Jr., Captain and Assistant Surgeon, will proceed to Zamboanga, Mindanao, Philippine Islands.
- MARSHALL, THOMAS R., Captain and Assistant Surgeon, will report to the commanding general, Department of Northern Luzon, Philippine Islands, for duty.
- PHILLIPS, JOHN L., Major and Surgeon, will report to the commanding general, Department of Northern Luzon, Philippine Islands.
- SHAW, HENRY A., Captain and Assistant Surgeon, will proceed to Vigan, Philippine Islands, and assume command of the Military Hospital at that station, relieving WESTON P. CHAMBERLAIN, First Lieutenant and Assistant Surgeon, who will proceed to Manila.
- STEPHENSON, WILLIAM, Major and Surgeon, will report to the commanding general, Department of Southern Luzon, Philippine Islands.

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine Hospital Service for the Seven Days ending February 14, 1901:

- GARDNER, C. H., Passed Assistant Surgeon. Granted leave of absence for seven days.
- GEDDINGS, H. D., Passed Assistant Surgeon. Granted leave of absence on account of sickness for eight days from

January 26th. Granted leave of absence for thirty days from February 3d.

KALLOCH, P. C. Surgeon. Granted leave of absence for three days from February 17th.

McCoy, G. W., Assistant Surgeon. Granted leave of absence for fourteen days from March 18th.

MOORE, DUNLOP, Assistant Surgeon. To proceed to Port Townsend, Washington, and assume temporary command of the service during the absence on leave of the medical officer in command.

PARKER, H. B., Assistant Surgeon. To proceed to the Gulf Quarantine Station and assume temporary command of the service during the absence on leave of the medical officer.

SAWTELLE, H. W., Surgeon. Granted leave of absence for thirty days from February 20th.

Marine-Hospital Service Health Reports:

The following cases of small-pox, cholera, and plague were reported to the surgeon-general during the week ending February 16, 1901:

Small-pox—United States.

Oakland, California.....	Jan. 12-26.....	4 cases.	
Jacksonville, Florida.....	Feb. 2-9.....	2 cases.	
Jeffersonville, Georgia.....	Feb. 7.....	2 cases.	
Calro, Illinois.....	Jan. 26-Feb. 9..	8 cases.	
Chicago, Illinois.....	Feb. 2-9.....	2 cases.	
Pulaski County, Illinois.....	Feb. 2-9.....	5 cases.	
Ottumwa, Iowa.....	Jan. 5-26.....	2 cases.	
Lawrence, Kansas.....	Feb. 2-9.....	3 cases.	
Wichita, Kansas.....	Feb. 2-9.....	9 cases.	
Lexington, Kentucky.....	Feb. 2-9.....	1 case.	
New Orleans, Louisiana.....	Jan. 2-9.....	14 cases.	4 deaths.
Minneapolis, Minnesota.....	Jan. 26-Feb. 9..	9 cases.	
Vicksburg, Mississippi.....	Feb. 2-9.....	4 cases.	2 deaths.
Omaha, Nebraska.....	Feb. 2-9.....	8 cases.	
Manchester, New Hampshire.....	Feb. 2-9.....	26 cases.	
New York, New York.....	Feb. 2-9.....	17 cases.	6 deaths.
Ashtabula, Ohio.....	Feb. 2-9.....	2 cases.	
Cleveland, Ohio.....	Feb. 2-9.....	48 cases.	1 death.
Toledo, Ohio.....	Feb. 2-9.....	1 case.	
Pittsburgh, Pennsylvania.....	Feb. 2-9.....	5 cases.	
Memphis, Tennessee.....	Feb. 2-9.....	16 cases.	
Nashville, Tennessee.....	Feb. 2-9.....	9 cases.	
Salt Lake City, Utah.....	Feb. 2-9.....	32 cases.	

Small-pox—Foreign and Insular.

Prague, Austria.....	Jan. 12-26.....	27 cases.	
Hong Kong, China.....	Jan. 5-12.....	1 case.	
Guayaquil, Ecuador.....	Nov. 24-Jan. 5..	25 deaths.	
Cairo, Egypt.....	Jan. 1-7.....	1 death.	
London, England.....	Jan. 19-26.....	3 cases.	
Newcastle-on-Tyne, England..	Jan. 19-26.....	5 cases.	
Paris, France.....	Jan. 12-19.....	6 deaths.	
Bombay, India.....	Jan. 1-15.....	6 deaths.	
Calcutta, India.....	Dec. 29-Jan. 5..	96 deaths.	
Karachi, India.....	Dec. 23-Jan. 6..	7 cases.	3 deaths.
Madras, India.....	Dec. 15-Jan. 4..	3 cases.	3 deaths.
Merida, Mexico.....	Dec. 20, 1900..	Epidemic.	
Tuxpan, Mexico.....	Jan. 28-Feb. 4..	3 cases.	3 deaths.
Ponce, Porto Rico.....	Feb. 3.....	22 cases.	
Moscow, Russia.....	Jan. 12-19.....	4 cases.	
Odesa, Russia.....	Jan. 12-19.....	31 cases.	5 deaths.
St. Petersburg, Russia.....	Jan. 5-19.....	6 cases.	2 deaths.
Glasgow, Scotland.....	Jan. 25-Feb. 1..	180 cases.	

Cholera.

Bombay, India.....	Jan. 1-15.....	9 deaths.
Calcutta, India.....	Dec. 29-Jan. 5..	31 deaths.
Madras, India.....	Dec. 15-Jan. 4..	19 deaths.

Plague.

Hong Kong, China.....	Dec. 29-Jan. 5..	2 cases.	2 deaths.
Hull, England.....	Jan. 30.....	2 deaths, crew of ss.	Friary.
Cardiff, Wales.....	Feb. 3.....	1 death.	
Bombay, India.....	Jan. 1-15.....	550 deaths.	
Calcutta, India.....	Dec. 29-Jan. 5..	28 deaths.	

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending February 16, 1901:

ALFRED, A. R., Passed Assistant Surgeon. Detached from the *Culgoa* and ordered to the Cavite Naval Station, Philippine Islands.

ARNOLD, W. F., Surgeon. Detached from the naval recruiting rendezvous, Chicago, and ordered to the *New Orleans*.

BAGG, C. P., Passed Assistant Surgeon. Detached from the Cavite Naval Station, Philippine Islands, and ordered to the *Culgoa*.

BIDDLE, C., Surgeon. Detached from the Naval Hospital, Norfolk, Virginia, and ordered home to await orders.

CORDEIRO, F. J. B., Surgeon. Detached from the *New Orleans* and ordered home to await orders.

GRIFFITH, S. H., Surgeon. Detached from the *Prairie* and ordered to special duty in the Bureau of Medicine and Surgery.

LEWIS, D. O., Surgeon. Detached from the *Iowa* and ordered to the *Philadelphia*.

MOORE, A. M., Surgeon, retired. Ordered to duty at the naval recruiting rendezvous, Chicago.

The Harlem Hospital.—We are informed that Dr. John J. McGrath has been appointed as attending surgeon by the charity commissioner.

Dr. Seymour Oppenheimer has been appointed consulting otologist and laryngologist to the Hebrew Sheltering Guardian Society of New York.

New York Physician Denies Story of Assault.—Dr. Alfred Meyer, of 801 Madison Avenue, New York City, denies that he is the physician who was assaulted at El Paso, Texas, about a week ago.

The Bellevue Nurses on Trial.—The trial of the three Bellevue nurses on the charge of manslaughter in the first degree in connection with the death of Louis R. Hilliard, a patient in the insane pavilion of Bellevue Hospital, is now going on in Part II of the Court of General Sessions in this city before Judge Cowing.

Diphtheria Antitoxine Infected with Tetanus.—Twenty deaths from tetanus were reported recently in cases which had been treated with a particular lot of diphtheria antitoxine made in Milan, Italy. A rigid governmental inquiry has been set on foot and all this lot of antitoxine seized.

To Conduct an Investigation for the Netherlands.—The government of the Netherlands has asked Professor J. Playfair McMurrich, of the medical department of the University of Michigan, to conduct a research and make a report on the actinians found in the neighborhood of the Malay Archipelago.

Isolation for a Consumptive.—Health Inspector Kleibey, of West Hoboken, made application to Recorder Hensel recently for the isolation of a consumptive at Snake Hill, where small-pox victims are usually kept. He took the ground that consumption was a contagious disease of which the State health board takes cognizance, and his application was granted.

Poisonous Effects of Methyl Alcohol.—The Medical and Chirurgical Society of Maryland will, it is reported, bring suit against certain wholesale druggists of Baltimore for having made and sold essence of Jamaica ginger in which methyl or wood alcohol was substituted as a solvent for ethyl, or grain alcohol. It is asserted that numerous cases of blindness have been traced to the use of the methyl alcohol extract.

A Bronze Monument to Dr. Skene.—A movement is on foot to erect a bronze monument as a memorial to the late Dr. Alexander J. C. Skene, and the following committee has been formed for the purpose of determining what can be done toward the erection of such a monument: George Foster Peabody, Spencer Trask, Alexander E. Orr, Royal Peabody, Charles A. Moore, John Claffin, Hugo Hirsh, and William H. Snyder.

Nurses to be Restrained from Violating Confidences.

—A bill has been introduced into the Assembly at Albany, N. Y., to restrict nurses from revealing information acquired in a confidential capacity concerning the ailments and afflictions of patients. The same restrictions as are now on physicians are placed on nurses, when acting under the direction of a duly licensed physician and surgeon.

City Restrained from Using a Detention Hospital.

—An injunction has been served on the authorities of the city of Gloversville, N. Y., restraining them from using the detention hospital at Smith's Corners, the injunction being granted by Judge Nisbet on application of M. D. Murray, counsel for the town of Johnstown, in an action in the supreme court to prevent the city from establishing a detention hospital in the town.

Physician Sued for \$5,000 Damages.—A singular suit to recover damages for the death of a child has been instituted in Philadelphia. In September last Mrs. Mary Nugent took her five-year-old son, John, to Dr. Harvey M. Richter, of 1443 South Second Street, for vaccination. A month later the little fellow died, and the mother, asserting that his death was due to blood poisoning caused by the use of impure virus, now brings suit for \$5,000.

The State Lunacy Commission Bill.—The Senate judiciary committee has reported favorably the bill repealing the requirement that the president of the State commission in lunacy shall be a physician with at least five years' experience in the treatment of the insane. Under the bill Governor Odell can appoint any physician who has practised his profession for ten years. The salary of the president of the commission and of his two associates is put at \$5,000, and each is to have \$1,200 a year for expenses.

Dental Surgeons for the Army.—With the approval of the Secretary of War, Surgeon-General Sternberg has arranged for the immediate appointment of thirty contract dental surgeons for service in the army in accordance with the provisions of the new army law. They must be graduates of standard medical or dental colleges, trained in the several branches of dentistry, of good moral and professional character, and are required to pass a satisfactory professional examination. An examining board of three members was first appointed, before whom all subsequent appointees must pass an examination.

Memorial to the Late Dr. Rohé.—A memorial meeting to the late Dr. George H. Rohe was held in Baltimore recently by the Medical Society of the College of Physicians and Surgeons. The president, J. M. Barry, of the graduating class, presided. Addresses concerning the life and work of Dr. Rohé were made by Professor William Simon, Professor Aaron Friedenwald, and Professor J. W. Chambers. Short tributes were paid to the memory of Dr. Rohe by Dr. Henry M. Hurd, Dr. Wilmer Brinton, Dr. William R. Stokes, Dr. Thomas A. Ashby, Dr. H. H. Biedler, and Dr. John F. Crouch.

Neurologists Object to Amendments of the State Lunacy Commission Laws.—The proposed amendments to the law providing for the State lunacy commission and prescribing the qualifications of the commissioners

do not meet with the approval of the local neurologists. At a recent meeting of the New York Neurological Society, held at the Academy of Medicine, resolutions were adopted condemning any amendment which does away with the clause providing that the medical member of the commission shall have had five years' actual experience in the care and treatment of the insane. Copies of the resolutions were mailed to members of the legislature at Albany. Opposition to the bill has also come from the board of managers of the State Charities Aid Association.

Against a Division of Fees.—A special committee of the Chicago Medical Society consisting of Dr. James H. Stowell, Dr. Frank Billings, Dr. J. B. Murphy, Dr. L. L. McArthur, and Dr. Edmund G. Wells, appointed to consider the matter of the division of fees, recommended the adoption of the following resolutions, which were adopted by a unanimous vote at a recent meeting of the society: "*Resolved*, By the Chicago Medical Society, that the soliciting or offering, giving or accepting, directly or indirectly, of any portion of a fee by a family physician, surgeon, or consultant, is dishonest, dishonorable, and unethical, and that any member of the Chicago Medical Society who shall be found guilty of such practice under such subterfuge shall be expelled."

A Dinner and Loving Cup to Dr. Quinlan.—A dinner was given and a loving cup was presented by a large number of physicians to Dr. Francis J. Quinlan in the banquet hall of the Hotel Gaston, New York, on February 7th. They had gathered to give testimony of their recognition of esteem and appreciation. Many speeches were made by members of the profession. Among those present were: Dr. Phelps, Dr. McGuire, and Dr. Smith represented St. Vincent's Hospital; Dr. John McGarth, the Post-graduate School; Dr. Joseph Bissell, Bellevue Hospital; Dr. Aspell, the Cornell Medical College; Dr. Bodine and Dr. Doherty, the New York Polyclinic; Dr. Thomas Manley, the Harlem Hospital; Dr. P. W. Burnett, the Brooklyn Eye and Ear Hospital; Dr. Laderman, Dr. Hepburn, and Dr. MacDonald, the Manhattan Eye and Ear Infirmary; Dr. Dalrymple, of New Rochelle; Dr. Nevin, of Jersey City, and Dr. Morris Manges, of Mount Sinai Hospital. The dinner was given under the auspices of the New York Celtic Society.

A Home for Physicians' Orphans.—A Physicians' Orphan Home, in which the medical profession throughout the country will be interested, is to be established in Bristol, Tenn., in the near future. The idea of a home for the orphans of deceased physicians originated with Dr. John S. Harris, of Pulaski, Giles county, Tenn. Dr. Harris is a relative of the late Senator Isham G. Harris. The organization has secured, in part, an elegant piece of property in Bristol, including a building of eighty-five rooms, and now has to raise only \$45,000 to pay the balance on this property, valued at \$100,000. When this amount is raised the orphanage can be put in operation. The plan of the organization is to raise eventually not less than \$300,000, the purpose being to erect additional buildings and provide a fund for the maintenance of the institution.

Additional Surgeons Needed for the Navy.—Serious embarrassment prevails in the navy because of the inability of the medical corps to obtain competent young physicians willing to accept appointment as assistant sur-

geons. There are now fifteen vacancies, and two more will occur during the year by the retirement of Medical Director W. K. Scofield, senior officer of the medical corps, and Medical Director J. G. Ayers. Numerous applications for appointment are received, but so soon as the applicants learn that the rank to which they will be appointed is only that of lieutenant, junior grade, they reply that they prefer to enter the army, which promises higher rank and a better future. Surgeon-General van Reyden says it is impossible to lower the standard, and it is probable that, in order to induce superior men to enter the service, Congress will be asked to authorize greater inducements.

Trial of Dr. Pease, Christian Scientist.—At the first hearing in the trial of Dr. Charles D. Pease, dentist, surgeon, physician, and dispenser of Christian Science, who is charged by the health department with having violated Section 153 of the Sanitary Code, which requires physicians to report to the health department within one week from the day of first treatment any case of contagious disease. Dr. Alonzo Blauvelt was the first witness called. The specific case against the doctor was that of Helen Camilla Brush, who died of consumption on July 7, 1900, and the nature of whose illness, the health authorities contend, Dr. Pease failed to report. Dr. Blauvelt admitted upon cross-examination that he himself did not know the woman who had died of consumption, nor the nature of her disease. He did not know, except from hearsay, that the woman had really died from a contagious disease. Dr. Wootton also said that he knew of the case only from hearsay. The trial was adjourned to February 28th.

No Epidemic of Small-pox in Chicago.—Dr. Arthur R. Reynolds, commissioner of health for Chicago, referring to a statement concerning an epidemic of small-pox in Chicago published in our issue for February 16th, informs us that there has not been any epidemic of small-pox in Chicago since 1894, and that no schools have been closed. From the appearance of the first case, in November, 1900, up to February 18th, one hundred and seven cases of small-pox have been reported, of which sixty-two were imported from surrounding States. On the date named there were thirty-nine cases in the isolation hospital, and among the whole one hundred and seven cases but one death has occurred. None of the employees of "The Fair" is or has been afflicted with the disease.

Small-pox.—Small-pox has been in evidence recently at Albany, N. Y., and its vicinity; at St. Joseph, Mo.; North Dakota, Nebraska, Washington, D. C., and New York City. A case was accidentally discovered on a trolley car in Staten Island. Deaths have been infrequent.—Dr. Matthew J. Rodermund, who purposely exposed himself and many other persons to small-pox contagion, holding that the disease is not contagious, has been released at Milwaukee, Wis., the period of quarantine having passed. Dr. Rodermund showed no symptoms of the disease, and there is no record of any one taking it through him. It is now said that the case to which he exposed himself was not in a contagious stage. The doctor threatens to bring suit against the city.—An anti-vaccination bill was presented in the Pennsylvania legislature recently. It repeals that section of the public health act which compels all principals or other persons in charge of public schools to refuse the admission of any child except upon a certificate signed by a physician

setting forth that the child has been successfully vaccinated or that it has previously had small-pox. In this connection it is not unlikely that Dr. G. C. Groff, formerly chief of the vaccination bureau of Puerto Rico, and brigade surgeon in the volunteer army, will be called upon to appear before the committee on health and sanitation when this bill comes before it. Dr. Groff, in a lecture in the House of Representatives, stated that one year ago there were 3,000 cases of small-pox on the island of Puerto Rico. The health authorities immediately ordered a general vaccination of all the inhabitants, and over 800,000 persons were vaccinated. When he left the island several months ago there were just three cases of small-pox reported in Puerto Rico.

The Detroit Medical Society held a meeting on February 6th. Dr. Albert E. Carrier read a paper on *The Doctor in Public Life*.

The St. Louis Medical Society of Missouri.—At the last regular meeting, on Saturday evening, the 16th inst., Dr. W. E. Saunders read a paper entitled *Veratrum Viride: Its Undeserved Neglect*.

The Calcasieu Parish Medical Society was organized at Lake Charles, La., on February 2d, and the officers are: President, Dr. E. J. Lyons; vice-president, Dr. V. A. Miller; secretary, Dr. C. P. Munday.

The New York Academy of Medicine.—At the last stated meeting, on Thursday evening, the 21st inst., Dr. A. Lartigau read a paper on *The Rôle of the Colon Bacillus in Human Affections*.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 27th inst., the following papers will be read: *A Remarkable Case of Glosso-pharyngo-labial Paralysis*, by Dr. Wolff Freudenthal; and *A Combined Intra-nasal and Extra-nasal Operation for the Correction of a Congenital Concave, Vertical, and Lateral Deformity of the Nose*, by Dr. B. S. Booth. Cases will be presented and new instruments and specimens will be exhibited.

The Philadelphia Neurological Society will hold a stated meeting on Monday, February 25, 1901, at 8.15 P. M., in the hall of the College of Physicians and Surgeons. Dr. William H. Teller and Dr. F. X. Dercum will exhibit *A Case of Astereognosis*. Dr. George L. Walton and Dr. Walter E. Paul, of Boston, will, by invitation, read a paper entitled *Astereognosis, with Illustrative Cases*. At the close of the meeting a reception will be tendered Dr. Walton and Dr. Paul at the University Club. Members and others are cordially invited.

Governor Odell Appoints Hospital Managers.—Abram S. Stothoff, of Schuylker county, N. Y., has been named by Governor Odell as manager of the Willard State Hospital to succeed himself, and Erwin C. Fisher, of Cattaraugus county, has been nominated to succeed Edwin H. Wolcott as manager of the Gowanda State Homœopathic Hospital for the Insane.

Alleged Kings County Hospital Abuses.—Adolph H. Goetting, commissioner of charities for Brooklyn and Queens, recently forwarded to the board of estimate and apportionment reports of physicians connected with the Kings County Hospital, which show a deplorable system of housing persons sent to that institution for the purpose of having inquiry made into their sanity. Because

they have no room, the physicians say, they are compelled to give up any attempt to classify patients, and must place in what is practically the same apartment raving lunatics and sufferers from melancholia, persons whose sanity is only under suspicion and alcoholic cases, criminals and other unfortunates.

The New Clinical Building of the Yale Medical School.—The anonymous gift of \$100,000, just made to the Yale Medical School, will be used for the construction and equipment of a clinical building, of which the school has been in great need. The building will be in the free Renaissance style, constructed of North Haven red brick and East Haven stone. The trimmings will be of Long Meadow stone and terra cotta. The inside arrangement will provide for a vestibule and a large hall, which will be used as a public waiting room, a room given over to orthopædics, and a surgical clinic, which will comprise four rooms. There will also be an apothecary room and prescription department. Four rooms will be occupied by the medicine clinic. There will be special clinics for the study of neurology, pædiatrics, obstetrics, gynæcology, laryngology, ophthalmology, and dermatology. There also will be a dark room, a lecture room, an x-ray room, baths, and physicians' rooms. The building will be fireproof and as little woodwork as possible will be used.

Hospital Buildings and Endowments.—An endowment of free beds in Chicago hospitals is proposed as a memorial to the queen. Former British subjects think that such an endowment would more fittingly perpetuate her memory than a monument or statue. This form was taken to commemorate the diamond jubilee, and free beds were then established in St. Luke's and the Presbyterian hospitals. There is a surplus of \$400, which sum will furnish the nucleus for the free bed fund.—A bill has been introduced into the California legislature appropriating \$10,800 to erect a hospital at the asylum for the deaf and dumb and the blind at Berkeley, Cal.—A bill has been introduced into the New York State legislature providing for the acquisition by the city of New York of certain lands and water rights around Ward's Island in the East River, as an addition to the grounds of the Manhattan State Hospital.—A bill has been introduced into the Senate authorizing New York City to expend \$200,000 for the establishment of a hospital in the Borough of the Bronx.—By the will of the late Nathaniel C. Brockway, of New Haven, Conn., \$2,000 each is left to the Albany Hospital and the New York Homœopathic Hospital and Dispensary.—The management of St. Luke's Hospital, Aberdeen, S. D., has decided to erect a fine brick and stone hospital building the coming summer. Plans and specifications are being prepared.—Ground has been broken for the Cable Memorial Building of the Evanston Hospital at Chicago. The new structure will have three stories and an attic, will cost \$25,000, and will provide thirty rooms for patients.

Births, Marriages, and Deaths.

Married.

BRINGIER—MCGALLIARD.—In Donaldsonville, Louisiana, on Saturday, February 9th, Mr. Mather Dubourg Bringier and Miss Jennie McGalliard, daughter of Dr. William M. McGalliard.

CASSIDY—HALL.—In Willimantic, Connecticut, on Tuesday, February 12th, Dr. Patrick J. Cassidy, of New London, Connecticut, and Miss Jane Hall.

DEACON—WARD.—In Oakland, California, on Thursday, January 31st, Dr. A. P. Deacon and Miss Louise J. Ward.

TREGO—LONG.—In Cleveland, on Thursday, February 7th, Dr. W. Edgar Trego and Miss Katherine L. Long.

Died.

BARCLAY.—In Newburgh, N. Y., on Monday, February 11th, Dr. Peter Moir Barclay, in the sixty-seventh year of his age.

BOND.—In Brooklyn, on Monday, February 11th, Dr. Frank Bond, in the seventy-fourth year of his age.

BUSEY.—In Washington, on Tuesday, February 12th, Dr. Samuel C. Busey, in the seventy-second year of his age.

CUNNINGHAM.—In Binghamton, N. Y., on Monday, February 11th, Dr. M. G. Cunningham, aged forty-eight years.

DOAN.—In Fremont, Nebraska, on Wednesday, February 6th, Dr. Ira Doan, of North Bend, Nebraska.

EDSALL.—In Highland Falls, N. Y., on Saturday, February 9th, Dr. William H. Edsall.

HESS.—In Oakland, California, on Tuesday, January 29th, Dr. Luther P. Hess, in the sixty-ninth year of his age.

KIRBY.—In Raleigh, N. C., on Tuesday, February 19th, Dr. George L. Kirby.

MANNING.—In Washington, on Saturday, February 9th, Dr. William P. Manning, aged fifty-six years.

MORRISON.—In Rockbridge Baths, Virginia, on Monday, February 4th, Dr. Samuel Brown Morrison, in the seventy-third year of his age.

MURRAY.—In Key West, Florida, on Saturday, February 16th, Rebah, second daughter of Dr. Robert D. Murray, United States Marine-Hospital Service.

PARSONS.—In Newark, N. Y., on Sunday, February 10th, Dr. Orrin C. Parsons, in the seventy-eighth year of his age.

PERKINS.—In Springfield, Maryland, on Thursday, February 7th, Dr. James Turner Perkins.

WEDGEWOOD.—In Lewiston, Maine, on Tuesday, February 5th, Dr. Newton J. Wedgewood, in the fifty-fourth year of his age.

Obituaries.

SAMUEL C. BUSEY, M. D., OF WASHINGTON.

DR. SAMUEL CLAGETT BUSEY, one of the oldest and most prominent physicians of Washington, and a man of national reputation, died on Tuesday, February 11th, in the seventy-second year of his age. He was a native of Maryland. Dr. Busey was not a voluminous contributor to medical literature, but his books and his articles in the journals were all characterized by soundness of judgment, learning, and clearness of expression. In 1876 he delivered the address in obstetrics and diseases of women and children before the American Medical Association. He was one of the early members of the American Gynecological Society, and served a term as its president. Perhaps his most notable work was a book entitled *Con genital Occlusion and Dilatation of Lymph Channels*, published in 1878. He was a graduate of the University of Pennsylvania, and for a number of years he was a member of the faculty of the Georgetown Medical College.

Dr. Busey was highly esteemed as a physician and as a man. He had rather a military bearing, and his personality was eminently attractive. He was as genial as he was handsome, and he will long be remembered by those of his professional brethren who were so fortunate as to know him personally, including almost all the more prominent men of his time. It was not in medicine alone that he was well known; he was a diligent worker in history, especially as it pertained to the District of Columbia.

Pith of Current Literature.

Philadelphia Medical Journal, February 9, 1901.

Case of Blindness from Sympathetic Ophthalmitis, Complicated with Secondary Glaucoma. Restoration of Vision by Two Iridectomies, One with Extraction of Lens, an Iridectomy, and Tyrrell's Operation of Drilling. By Dr. Charles A. Oliver.

A Case of Unilateral, Progressive, Ascending Paralysis. By Dr. William G. Spiller.—The author refers to a similar case, reported in April by Dr. C. K. Mills, and it would seem that medical literature affords no other case that corresponds with these two. The possibility of a cerebral lesion implicating, first, the centre or the nerve fibres for the lower limb, and, later, those for the upper limb and face, must be considered. Dr. Mills believes that a gradual degeneration of one pyramidal tract would best explain the symptoms in his case.

Cavite Fever. By Dr. B. L. Wright.—This is an acute infectious disease, characterized by an abrupt onset, high temperature, severe muscular pain, and extremely tender and painful eyeballs. The exciting cause is undoubtedly micro-organismal; the predisposing causes are high temperatures, low, damp localities, overcrowding, and proximity to salt water. The period of incubation is from two days to two weeks, and every newcomer at the Cavite Naval Station contracts the disease within the first two or three weeks—hence its name.

Exophthalmic Goitre of Syphilitic Origin. By Dr. R. Abrahams.—The author presents three cases of exceeding interest, and his conclusion seems to be justified, in part, that the old dictum relegating the origin of exophthalmic goitre to a disturbance in the cervical sympathetic system should receive attention only after the existence of syphilis, present or past, has been absolutely excluded. Those cases which yield to mercury or iodides should be favorably looked upon as being of syphilitic origin.

The Surgical Importance of Apparently Simple Carbuncles and Furuncles of the Upper Lip. By Dr. Charles A. Powers.—Unless these carbuncles or furuncles are promptly and thoroughly excised, rapid thrombosis of the facial veins, extending to the cerebral sinuses, is apt to ensue, and a speedy and fatal pyæmia supervenes. Excision had best be done under general anæsthesia. The danger in all these cases is, not from the bacteriological form of the infection, but from its location.

A Case of Cocaine Habit of Ten Months' Duration Treated by Complete and Immediate Withdrawal of the Drug. By Dr. George William Norris.—Strychnine sulphate, one thirtieth of a grain, every quarter of an hour, and sulphonal, twenty grains, repeated in two hours, was the only therapeutic substitution, yet the patient, after twelve hours, experienced no ill effects from the complete withdrawal of the cocaine and was pronounced cured after one week. The author asserts and regrets that cocaineism is yearly becoming much more common.

Report of a Case of Enormous Ventral Hernia; of a Case of Dermoid Cyst of the Ovary; and of a Case of Profound Shock Following a Crush of the Arm. By Dr. Francis T. Stewart.

The Treatment of Postoperative Hernia. By Dr. Irving S. Haynes.—According to the author, the radical treatment depends for its success upon two factors:

First, isolation of the various layers forming the abdominal wall; and, secondly, the accurate and separate apposition of the several layers for a sufficiently long time to obtain solid union. Rest in bed for at least three weeks should be observed when possible.

On the Dietetic Management of Typhoid Fever. By Dr. David Inglis.—The author argues with much cogency against the use of milk as a diet in typhoid fever; it is logically unsound. Milk is a liquid in the tumbler, but we ought to think of it as a solid food. It becomes solid in the stomach, it enters the small intestine a solid, and it passes through as a solid. He advocates the use of sugar. In reality sugar is highly nutritious—no other hydrocarbon is more promptly and easily absorbed—and it leaves no detritus. A typhoid patient can take it up rapidly.

Sudden Death in Pleurisy. With Report of a Case. By Dr. Charles Lewis Allen.—This occurrence, though exceptional, is by no means uncommon. Of ten cases of which Leichtenstern gives a summary, nine were due to thrombosis and one to embolism.

February 16, 1901.

Perforating Ulcer of the Stomach; Operation; Recovery. By Dr. John H. Musser and Dr. Henry R. Wharton.

Recent Progress in the Treatment of Acute Lobar Pneumonia. By Dr. James K. Crook.—The author speaks strongly against the promiscuous drugging which is still only too prevalent, and he concurs in the admonition of late writers to withhold drugs until the indications for them arise. The use of antipyretics is condemned by almost all the writers of the year. Regarding the use of opiates, however, the profession is still at variance, while the best sense of the profession at the present day is not in favor of the routine use of alcohol in pneumonia. On the use of antipneumotoxine nothing can be said, and the net result of the year's endeavors appears to leave us about where we were one year ago. The study of antipneumotoxine is still in an elementary phase of development, and we must await further progress before expressing positive opinions as to its value.

Periodical Insanity. By Dr. A. R. Defendorf.—Periodical insanity is a mental disease characterized by a definite symptomatology, course, and outcome, and in point of numbers is one of the most prominent psychoses. The symptoms are sufficiently characteristic to permit a distinction between it and other forms of mental disease in the first attack, and to allow of a forecast of the whole course of the disease, *i. e.*, recurrence of attacks throughout the life of the individual, mostly of the character of the first, with lucid interval of a length varying from weeks to years, except in a very small percentage of cases, without a tendency to mental deterioration, except in cases where the attacks have been long, frequent, and severe, and even then it is of a light grade.

Medical Examination of School Children. By Dr. Edward M. Greene.—In regard to establishing a system of daily medical inspection in all public schools, important questions arise as to how comprehensive and searching an inspection is desirable or practicable, and how to organize and conduct the work in the most efficient manner. With the purpose of answering these questions, the author gives the details of the system in use in Boston and the results of seven years' experience as a medical inspector.

Tetanus Following Clean Operation Wounds. By Dr. Joseph B. Bissell.—The author reports two cases which apparently justify his choice of heading for this article. He says, however, that such adjectives as idiopathic, rheumatic, spontaneous, and auto-infectious, to describe the cause of tetanus, are subterfuges unworthy of the scientific. As regards antiseptic measures, the author says that the ordinary disinfection of the hands and the wound, as practised in hospitals and in private cases, will not destroy this bacillus; and, until we have some more certain way than that at present in use, we can never be sure, in the presence of this bacterium or its spore, of preventing tetanus. In treatment, a combination of the serum treatment, chloral, and the bromides should always be used, and it offers the best hope of a favorable result.

Adhesion of the Soft Palate to the Posterior Wall of the Pharynx. By Dr. Augustus Koenig.

The Treatment of Erysipelas. By Dr. N. G. Keirle.

Boston Medical and Surgical Journal, February 7, 1901.

Gonorrhœal Infection. By Dr. Benjamin Tenney.—The author endorses the conclusion of Guiard that every case of urethral inflammation lasting more than a few days is, or, at least, may have been, at the start a true infection by the gonococcus. Reference is made to the recent work of Christmas, who, from the gonococci cultivated on a medium composed of three parts of human ascitic fluid with one part of rabbit bouillon, has produced a poison, .002 of a cubic centimetre of which kills a guinea pig in from five to seven hours. Smaller doses produce death after a longer time or else a form of intoxication from which the animal recovers with a certain acquired immunity to the poison. He has succeeded in producing a powerful antitoxic serum, which has, however, no effect when injected *after* the toxine. It remains to be seen whether this work has any practical value to the human animal. As to the proportion of the community which becomes infected at some period of life, the author's impression is that twenty per cent. of the males and five per cent. of the females are involved, but no more.

The Bacteriological Diagnosis of the Gonococcus. By Dr. Oscar Richardson.—The author comments on the frequent negative results of the bacteriological examination of inflammatory conditions supposed to be due to the gonococcus. He explains these results as being due to the destruction of the gonococci after their arrival in the tissues, and not to the results of a toxine imported there from a distance. It is also known that the bodies of dead gonococci have irritating and pyogenic properties.

Treatment of Acute Gonorrhœa. By Dr. Franklin G. Balch.—As to injections, the author has been more successful with nitrate of silver than with anything else. It is unwise to use a solution of greater strength than three grains to the ounce. The author has obtained good results from the use of methylene-blue internally. It is best given in capsules containing one grain of methylene-blue, one drop of oil of cassia, and one drop of oil of sandalwood. Three capsules a day are of use. Excepting peppery and spiced foods, there are few things that do harm in the diet, though a simple diet is best. Quiet is necessary; a suspensory bandage lessens the liability to epididymitis; alcohol should be avoided.

Gonorrhœa in Women. By Dr. W. L. Burrage.—The author has written an excellent text-book article on

the subject. In suspected cases, he recommends examination near the menstrual period, because relatively few gonococci at the intermenstrual time may be multiplied into many at the menstrual epoch.

Treatment of Chronic Gonorrhœa. By Dr. Gardner W. Allen.—In the treatment of this condition the objects to be aimed at are the removal of fibrous deposits, the restoration of the thickened and rigid mucous membrane to approximately its original soft and elastic condition, and the cleaning out of diseased follicles and glands. For local applications through the endoscope, nitrate of silver in solutions of a strength of from three to ten per cent. gives the best results.

The Seminal Vesicles in Gonorrhœa. By Dr. Charles L. Scudder.—The author lays great stress upon the importance of examining the urine in cases of acute seminal vesiculitis. Massage of the vesicles should be tried before resorting to extirpation, which should be reserved for extreme cases associated with serious or severe subjective symptoms.

Gonorrhœal Prostatitis. By Dr. John Babst Blake.—The treatment of the chronic condition consists of cold baths, general tonics, healthful habits, and, locally, cold sounds, deep injections of nitrate of silver, and, in the absence of acute symptoms, massage of the prostate.

Gonorrhœal Conjunctivitis. By Dr. Charles H. Williams.

When is a Gonorrhœa Cured? By Dr. Paul Thordike.

February 14, 1901.

A Case of Cæsarean Section for Complete Placenta Prævia. By Dr. C. H. Hare.—In this case the mother died eleven hours after the operation, and the child died of acute inanition when thirteen days old. Both would probably have survived had the operation been done when first advised. The author believes that Cæsarean section, in most cases, is fully as safe for the mother as delivery by the older methods, and that Cæsarean section will save far more babies.

The Woolen Yarn Truss in Infantile Inguinal Hernia. By Dr. E. S. Boland.—The author argues that the use of some retentive apparatus will hasten and assure the natural tendency toward cure in infantile hernia, and, in favor of the woolen yarn truss, he asserts that it is easily made to measure at the bedside; it is cheap and comfortable and can be worn by frail or delicate infants where the ordinary truss would be useless or too irritating. With this or any other truss, however, vigilance and intelligence must counteract the underlying or associated causes of the hernia.

Disinfection Within or Without the Body in Diphtheria. By Dr. M. A. Veeder.—The author lays great stress upon the danger of the physician infecting his own patients, and it is the author's practice to be provided with squares of antiseptic gauze and corrosive sublimate tablets. A square of such gauze is held over the mouth and nostrils with the left hand, while the right is free to use the tongue depressor or swab. Both hands and face are wetted, before and after, with the sublimate solution, and the gauze is burned after using it. The fact that the diphtheria bacillus does lodge in cavities of the teeth and grow therein is used as a text in urging that a great amount of care be taken to rid the mouth and throat of diphtheria infection by methods of disinfection.

A Case of Idiopathic Dilatation of the Colon. By Dr. Maurice H. Richardson.—The explanation of the

dilated and hypertrophied coil lies in the existence of some kind of a chronic intestinal obstruction, the nature of which we do not as yet understand. Surgical intervention would seem to offer but a temporary relief, as a recurrence of the condition is common—the author's case is no exception.

Placenta Prævia Centralis: Report of a Case. By Dr. John W. Dewis.—A striking point in this reported case is that there had been no hæmorrhage and no warning of danger throughout pregnancy, and yet it proved a complete "placenta prævia." The author believes that the general practitioner who does obstetrical work should be competent to do a Cæsarean section.

A Case of Complete Placenta Prævia. By Dr. Frederick Coggeshall.—In this case the mother recovered, but the child died on account of the lack of proper care.

Medical News, February 9, 1901.

Some Unusual Cases of Infectious Diseases—A Clinical Report. By Dr. Delancey Rochester.

Remarks upon the Construction of Amputation Stumps, with a Report of Two Cases of Amputation by the Osteoplastic Method of Bier. By Dr. Alexis V. Moschowitz.—The author believes that Bier's method of amputation is the operation *par excellence* in all cases, with the exception, perhaps, of diabetic and senile gangrene.

Parasites in the Blood. By Dr. Leon T. Le Wald.

General Remarks on the Combination of Ether (57 parts) and Chloroform (43 parts) Known as the M. S. Mixture. By Dr. Edward Adams.—According to the author, the chief advantages of M. S. are the following: (1) Stage of excitement and struggling are not so marked; (2) short time required to get the patient under; (3) small amount of the anæsthetic required, about forty cubic centimetres an hour; (4) it is a comparatively safe anæsthetic; (5) it is very pleasant to take; (6) the after-effects are not marked; (7) patients recover quickly; (8) it can be used in nearly every condition in which either chloroform or ether is employed.

A Report of some Cases of Abdominal Surgery, with Remarks on the Diagnosis of Carcinoma of the Cæcum and the Surgical Treatment of Carcinoma of the Liver and Gall-bladder. By Dr. Charles Greene Cumston.

February 16, 1901.

A Hair-cast of the Stomach; its Successful Removal by Laparotomy. By Dr. Nathan Jacobson.—There have been but nineteen similar cases previously recorded. In nearly every instance the habit of hair-swallowing was of years' continuance. Of the nineteen cases, ten were discovered *post-mortem* and nine upon the operating table. All those operated upon, including the author's patient, a girl of eleven, recovered.

Scurvy and Rickets in Young Children. By Dr. H. A. Hare.—The peculiar characteristics of scurvy in infants are the very grave appearance of the child when suffering from the disease in its severe forms, the rapidity with which it improves under proper treatment, and the rarity with which death occurs as a direct result of the malady, since a fatality is usually produced by some intercurrent disease, which speedily saps the vitality of a child whose vital resistance is already so impaired. The author points out, as a particular feature, that this disease is distinctly a disease of the well-to-do, as distinguished from rickets, which seems to be a disease of

the poor. He condemns, as a cause of scurvy, the use of artificial foods for long periods of time. When scurvy has developed as a result of the use of these foods, they should be cut out of the diet list and natural food should be largely introduced; orange juice should be freely given, and beef juice should, for a time at least, form an important part of the child's food.

The Relation of Tuberculosis to the Tenement House Problem. By Dr. Arthur R. Guerard.—The author points out many of the evils that result from overcrowding and insanitary conditions in tenements. It has been repeatedly observed that some houses in these overcrowded districts, after a time, seem to become permanently infected with tuberculosis, as evidenced by a repetition of cases of the disease. There can be but little doubt that in many instances such a "family house" is a far more important factor in the production of consumption than any supposed "family predisposition." Putting a pecuniary value on the lives and services of consumptives, the author estimates the annual loss to the city of New York at eight and a quarter million dollars. By these and similar arguments, the author urges the combination of all interests in the great work of practical sanitation.

Treatment of Lupus. By Dr. H. Rockwell Varney.—After a general consideration of the subject, the author turns to the treatment by means of exposure to the x-rays. He believes that the stimulating influence on the tissues exercised by the x-rays is produced by the action of the stronger chemical colors. After describing an experiment which proved that the only effect of the x-rays upon tubercle bacilli was to accelerate their growth, he concludes that the action of the x-rays on lupus lesions is not an antiseptic one. A typical case in which this treatment produced a favorable effect is given.

A Report of Some Cases of Abdominal Surgery, with Remarks on the Diagnosis of Carcinoma of the Cæcum and the Surgical Treatment of Carcinoma of the Liver and Gall-bladder. By Dr. Charles Greene Cumston.—The author believes that at the present time the only proper treatment of cases of carcinoma of the gall-bladder and of the liver is cholecystectomy and resection of the diseased portion of the liver. A cholecystectomy as a typical operation should be confined to cases of severe inflammatory lesions and malignant tumors of the gall-bladder.

Pregnancy and Typhoid. By Dr. G. H. B. Terry.—A case that demonstrates that pregnancy does not confer immunity to typhoid, and, also, that it does not necessarily interfere with its favorable termination.

Foreign Body in the Urethra. By Dr. H. W. Clouchek.—A seven-inch straw of "barn grass" used as a catheter was the offending substance in this case.

Medical Record, February 9, 1901.

Summary of the Progress Made in the Nineteenth Century in the Study of the Propagation of Yellow Fever. By Dr. Charles Finlay.—The author gives a very interesting account of the evolutive phase of the mosquito theory. He considers it to be proved with almost mathematical precision that the *Culex fasciatus* does transmit the disease from one patient to the next, and also that when the contaminated mosquito has been excluded the yellow fever infection is no longer transmitted.

Investigations upon Corporeal Specific Gravity, and upon the Value of the Factor in Physical Diagnosis. By Dr. Heinrich Stern.—By the author, the body density of an individual is considered to be an important factor in estimating: 1. Body soundness; a volume weight in the healthy adult male below 1.063 or above 1.073 denotes unsoundness of the organism. 2. Body immunity; a volume weight below the normal signifies that the system is predisposed to infectious disease; one above the normal announces its susceptibility to, or the presence of, eliminative disorders. 3. Qualifications as to physical work; a volume weight above or below the normal indicates a lack of the strength and endurance that accompanies the normal. 4. Probable duration of life; individuals whose specific gravity is abnormal should be considered bad risks by life assurance examiners.

Abnormal blood densities undoubtedly correspond to abnormal body densities.

The Use of the Aqueous Extract of the Suprarenal Capsule as a Hæmostatic. By Dr. W. H. Bates.

The Clinical Significance of Dulness in Appendicitis. By Dr. J. H. Miller.

February 16, 1901.

The Problem of Appendicitis from the Medical and Surgical Points of View. By Dr. Robert Abbe.—In an exhaustive article, the author deals with a subject which has few rivals in the surgical field, and takes rank to-day with typhoid, pneumonia, and rheumatism in medical thought. The fact that when operations are properly done there need be hardly any deaths does infinite credit to modern surgery. The glaring inaccuracy of comparative estimates of cures by medical and surgical measures is self-evident, when we realize that every case coming to operative cure represents from five to twenty medical cures, for careful search of the histories shows every patient to have been under physicians, time and again, in previous years for a two days' or a week's illness, and each time "cured." A medical cure means only that a lull has occurred. As to the cases of spontaneous recovery, the author expresses himself as being ready to believe that every cell is sentient and acts with a purpose by volition, "for will cannot be placed in any cell or group of cells, and why may it not be universal?" He thinks it possible, apparently, that there may be concerted action among the body cells to produce a cure, just as Lubbock's ants "build, colonize, police, go to war, lay by stores for seasonable use, etc."

The Causes of Failure of Compensation in Diseases of the Heart. By Dr. Morris Manges.—The author refers with special emphasis to a class of cases in which the failure of compensation is not due to disease, but to the physician, or to the patient himself. By this he refers to the abuse and improper administration of cardiac drugs by doctors to whom the presence of a murmur is the signal for the prompt and heroic administration of digitalis, etc. The constant and uncalled-for demands upon the reserve energies of the heart by such means not infrequently precipitate cardiac failure. At present, according to the author, the abuse of the Nauheim method, Zander exercises, etc., in the hands of many physicians is doing more harm than good in destroying compensation rather than in improving the condition of the heart. Following fads is one thing; judicious employment of these rational methods after comprehending these underlying principles is another.

Strabismus and its Management. By Dr. J. H.

Woodward.—In conclusion, the author states that heterotropia is vastly more difficult to deal with satisfactorily than are most cases of cataract, notwithstanding that the truth of the proposition depends upon one's conception of what constitutes a good result. Operations for heterotropia should not be undertaken by one who is not familiar with the anatomy, physiology, and pathology of the visual apparatus; and only those operators whose technique is characterized by a scrupulous surgical cleanliness should be permitted to engage in such work. In general terms, we have to deal (in non-paralytic strabismus) with an over-acting and often contracted muscle on the one hand, and on the other with an over-stretched and enfeebled muscle. The principle that ought to control operative interference is that we should weaken the one by judicious tenotomy, and strengthen the other by advancement of its insertion. Upward deviation, so often overlooked in convergent strabismus, must be corrected by "graduated" tenotomies, in order that the object sought may be obtained. The ideal result consists not only in reduction of the apparent squint, but in the establishment of normal binocular excursions of the eyeballs, and in restoration of binocular vision.

Journal of the American Medical Association, February 9, 1901.

The Technique of Bloodless Work. By Dr. Robert H. M. Dawbarn.—The author describes the present method of stripping by the fingers, for some minutes, the blood out of the elevated limb and then applying constriction at the desired point by means of a stout rubber bandage or a very large rubber tube. In applying constriction we should *select* the middle of the thigh and *avoid* the middle of the arm. When there is reason to fear collapse from the anæsthetic, the author recommends the manœuvre suggested by Dr. David Webster, who advised the maintenance, by cording the extremities, of a reserve guard of some quarts of pure blood. By the application of Spanish windlasses to the extremities, an attack of apoplexy, which might otherwise prove fatal, may very often be reduced to a comparatively small one.

Analgesia from Spinal Subarachnoidean Cocainization. By Dr. John B. Murphy.—In a conservative article the author gives the present status of this method of inducing analgesia, and has made an attempt to collate all the cases reported to the present time. Of the 631 cases, the method was successful in 596, partially so in 14, while in but 21 cases did failure result. Of the substitutes for cocaine, the author mentions eucaïne β and antipyrine as being used either separately or in combination with cocaine or morphine.

Rheumatic Diseases of the Eye. By Dr. H. W. Woodruff.—The author reports three cases representing, respectively, iritis, episcleritis, and scleritis of undoubted rheumatic origin.

Ovulation and Menstruation not Interdependent Functions. By Dr. C. C. Thayer.—In support of his contention, indicated in the title, the author reports cases of ovulation occurring apart from menstruation, and *vice versa*, and asserts that, in Syria and Asia Minor, where girls marry before the appearance of the catamenia, it is not unusual for a child to be born before the mother has menstruated.

Dysmenorrhœa. By Dr. George Tucker Harrison.—In the matter of local treatment, the author agrees with the view expressed by Fritsch that, by the gradual dilatation with laminaria tents, better results can be ob-

tained than by the use of forcible dilatation at one sitting. With strict aseptic and antiseptic precautions no infection need be feared.

Treatment of Menorrhagia of Pelvic Origin by Electricity. By Dr. G. Betton Massey.—According to the author, the electricity does not owe its value in these cases to its dilating effect, but rather to the cure of the endometritis.

Movable Kidney from the Standpoint of the General Practitioner. By Dr. Alexander Marcy.—The author recommends the examination of every person who weighs less than one hundred and twenty pounds and who complains of general nervous symptoms, indigestion, palpitation, etc., for movable kidney. Two, or even three, examinations may be necessary to demonstrate the condition. The medical treatment would consist in the use of such measures as would improve the general health of the patient, together with the accumulation of surplus fat. The rest treatment is only temporarily beneficial. Tincture of nux vomica in large doses, together with cold douching of the spine, followed by brisk rubbing, will benefit the nervous system. The value of the mechanical treatment is doubtful. The ideal treatment is the surgical.

Some Notes on the Climatology of Arizona. By Dr. William Duffield.—The author regrets the absence of climatological teaching and the dearth of literature pertaining to the subject. As for Arizona, it offers any altitude from sea level to 13,000 feet, and it has mineral and thermal springs whose virtues are just beginning to attract attention. There is a maximum of sunshine with a minimum of moisture.

Preventive Treatment of Migraine. By Dr. E. W. Mitchell.—The regulation of the diet is important, and red meats, rich and highly spiced foods, coffee, tea, and alcoholic beverages are to be avoided. Meals should be taken at regular intervals and overloading of the stomach should be avoided. Plenty of outdoor exercise should be taken, and the medicinal treatment should regulate the bowels, promote intestinal antiseptics, and stimulate the liver. The various salicylates are all useful, and in obstinate cases an occasional mercurial is required.

Cases Illustrating the Value of Rectal Injections of Salt Solution in Hæmorrhage and Threatened Collapse. By Dr. T. B. Greenly.

Physiologic Resuscitation of the Stillborn. By Dr. Daniel Lichty.

Clinical Report. Case of Ectopic Pregnancy. By Dr. J. Henry Barbat.

February 16, 1901.

The Major Obstetrical Operations. From the Standpoint of the General Practitioner, with a Tabular Report of Twenty-three Consecutive Successful Cases. By Dr. Edward Reynolds.—When the mechanical conditions make the intrapelvic delivery of an intact child at term impossible or unduly difficult, the author believes that the great superiority of Cæsarean section over the induction of premature labor in foetal mortality, and its extremely low maternal mortality, render it the preferable operation. When the ordinary operations fail and the woman is in the unfavorable class, symphysiotomy is the operation of choice, and may be expected to lead to a favorable result for both mother and child in the great majority of cases, provided always that the degree of mechanical difficulty permits of its application. When in

the unfavorable class of cases, the degree of relative disproportion between head and pelvis is too great to admit of a safe symphysiotomy, craniotomy to the living child should be unhesitatingly chosen, since the maternal mortality of either form of the section is so enormous.

Treatment of Sessile and Certain Other Ovarian Cysts. By Dr. H. B. Stehman.

Paralysis Agitans without Tremor. By Dr. Augustus A. Eshner.—Though, strictly speaking, the tremor was not wholly absent, it was at times so inconspicuous as not to be viewed as a symptom of importance, much less of diagnostic utility. The author's object in reporting the case is to invite renewed attention to the fact that the disorder under consideration may be unattended with tremor, and, further than this, when present, may be accentuated by voluntary action.

New Methods for the Application of Old Principles in the Treatment of Fractures and Deformities of Limbs. By Dr. James G. Hughes.

Possibilities of Liquid Air to the Physician. By Dr. A. Campbell White.—The author considers liquid air to be preferable as an anæsthetic in many cases—for example, opening of an abscess, incising a paronychia, and in cardiocentesis, and paracentesis thoracis or abdominis. He mentions also the almost invariable success resulting from the application of liquid air over the spinal end of the nerve in neuralgias and herpes zoster. In lupus and carcinoma, and as a stimulant in the treatment of chronic ulcers, it is of use, and also as a cauterizer.

Movements of Intestines. By Dr. Albert Bernheim.—This paper consists mainly of the report of the author's experiments with anæmias, by which he demonstrates the possibility of carrying medicine to the stomach by means of rectal injections. To a mulatto, for instance, who had previously been fasting, was given by anæmia three hundred cubic centimetres of a physiologic salt solution, with the addition of twenty-five grape seeds. Five hours later, in vomited fluid, three grape seeds were discovered. Of a total of twenty such experiments, thirteen proved positive. Whether antiperistalsis is the rule or the exception, however, will have to be demonstrated by further experiments.

The Ætiology of Yellow Fever. An Additional Note. By Dr. Walter Reed, Dr. James Carroll, and Dr. Aristides Agramonte.—At the end of a very interesting paper the authors briefly recapitulate their conclusions. The *Culex fasciatus*—the intermediate host for the parasite of yellow fever—becomes capable of conveying the infection when an interval of twelve days have elapsed since its own contamination. An experimental form of the disease can be produced by the subcutaneous injection of blood taken from the general circulation during the first and second days of this disease. An attack of yellow fever produced by the bite of the mosquito confers immunity against the experimental form of the disease. The period of incubation has varied in thirteen cases of experimental yellow fever from forty-one hours to five days and seventeen hours. Yellow fever is not conveyed by fomites. The spread of yellow fever can be most effectually controlled by measures directed to the destruction of the mosquitoes and the protection of the sick against the bites of these insects. The specific cause of the disease remains to be discovered.

The Metric System. By Dr. Frank G. Wheatley.—The system is recommended because (1) it is simple, (2) it saves time, (3) it is cosmopolitan, (4) it is scientific, (5) it is in use in the United States Coast Survey

Service, in the Marine-Hospital Service, and in the United States Army.

Evolutional and Involutional Types of Mental and Nervous Disease. By Dr. Edward E. Mayer.—The author considers the different epochs of life as factors in the production and in the exacerbation of nervous instability, and he asserts that they are rarely passed through, even in the most healthy individual, without some psychical or physical manifestation. In childhood, inherited strain is rarely noticed. In writing of the period of childhood the author refers to the transient exaltation so common among children. Parents stand complacently observing it and do not seek to repress this unnatural excitation until suddenly the picture changes, the child becomes listless, cries, and upon being taken to bed tosses about, and after it has gone to sleep, awakes frequently with a cry of anxiety. Further on he says that even the laity is apt to be suspicious of a too bright mind in a frail body, and he asserts that most often a neurotic taint is back of it.

Lyon médical, January 20, 1901.

Albumosuria (Bence-Jones) and Albumosic Urines.—M. L. Hugoung says that the albumoses, the intermediate products between the peptones and the albumins, may be divided into two distinct groups: 1. Albumosuria of Bence-Jones, characterized by the fact that heated urine, without the addition of any chemical, is coagulated at about 212° F., and redissolves on boiling. It is very rare and is seen mainly in skeletal diseases, as in osteomalacia. 2. Ordinary albumosuria, without the characteristic sign of the first group. It is frequently seen in nephritis, but may exist independently of it.

True Calcification of the Lung. M. Devic and M. Peviot.—A pathological study. (*Concluded.*)

Presse médicale, January 19, 1901.

Disturbances of Sensation in Syringomyelia. By M. E. Huet and M. Georges Guillani.

Combinations of Terebene with Phosphorus, Iodine, and Bromine. By M. J. Hulot and M. F. Ramond.

Prognosis of Typhoid Fever by Cryoscopy of the Serum.—M. R. Romme says that the elevation of the cryoscopic point (Waldvogel) of serum is not always attributable to uræmia; in typhoid fever it stands in relation to the formation of antitoxines. If, in a given case of typhoid fever, the cryoscopic point sinks a little below normal and remains at or goes below 0.7, the prognosis becomes very grave.

Gazette hebdomadaire de médecine et de chirurgie, January 24, 1901.

Clinical Researches upon the Respiration, Laughter, Crying, and Yawning of Hemiplegics (*abstracted from the Italian*).—M. Giovanni Boeri says that the two cerebral hemispheres do not, so far as can be proved, act with absolute harmony in controlling the automatic or synergetic functions exercised on the two halves of the body. Thus, the two sides of the thorax do not expand equally in quiet or forced respiration or in the respiratory acts accompanying the so-called psychoreflex functions, such as laughing, crying, and yawning. In hemiplegics, the paralyzed side may show an increased movement in automatic acts in striking contrast to the diminished motility in the voluntary muscles. This may be due to a heightened excitation or to a suppressed in-

hibition (as in a cortical lesion). The exaggeration of respiratory movements in an access of convulsive laughter or crying on the paralyzed side is not necessarily followed by a similar exaggeration during quiet respiration. The author believes that the bulbar centres presiding over tranquil breathing will be found to be distinctly different from the tracts controlling the augmented thoracic movements in convulsive laughing, crying, and yawning. When these tracts can be differentiated, new elements for the localization of certain cerebral lesions will have been found.

Revue de médecine, December 10, 1900.

Ætiology of Vitiligo.—M. E. Gaucher divides the pigmentary dystrophies of the skin into two classes: (1) vitiligo of nervous origin; (2) vitiligo of toxic origin. In the latter group are included the chronic changes due to poisons, as arsenical melanoderma, the leucomelanitic, cutaneous disturbances of syphilis and leprosy, and the vitiligo of disordered nutrition.

Re-education of the Movements of the Heart by Methodical Exercises. By M. F. Lagrange. (*Continued article.*)

Variations in Oxyhæmoglobin of Nurslings Treated by Injections of Artificial Serum.—M. Labbé says that newborn infants possess a larger percentage of oxyhæmoglobin than adults, averaging from fifteen to sixteen per cent. In pathological conditions, the oxyhæmoglobin becomes diminished by the injection of artificial sera, although the weight and general condition show an improvement. The change is due either to the dilution of the blood or to the lack of manufacture of new blood because of the exhaustion of the blood-making organs. From these data the author concludes that it is not wise to prolong the use of artificial serum for too great a time in infants.

Heroine as a Substitute for Morphine. By M. A. Morel-Lavallée.

Pleurotyphoid.—M. P. Remlinger reports eight cases of typhoid complicated by pleurisy. The author regards the condition as a distinct entity. The prognosis of pleurisies complicating typhoid fever is always serious, and is grave if the effusion is purulent. The later such a pleurisy appears, the more likely it is to become purulent. The effusion is usually on the left side, subacute in its course, and slow of absorption.

Notes on Chinese Medicine. By M. J. Regnault.

Gastric Crises and Syringomyelia.—M. R. Pauly and M. R. Pouly report a case of undoubted syringomyelia with gastric crises. The point raised is interesting as showing the relationship between syringomyelia and tabes.

Origin of the Leucocytes in Bone Marrow.—M. O. Josué says, as a result of his experiments, that in infections the bone marrow produces leucocytes. He has found them in all forms, except the lymphocytes, from myelocytes to polymorphonuclear forms. It appears that the products of the development of the staphylococcus are active in infections, in evoking the leucocytotic power of the bone-marrow, rather than the influence of the nervous system.

Centralblatt für Gynäkologie, January 12, 1901.

On Gersuny's Paraffin Injections for Urinary Incontinence.—Dr. J. Pfannenstiel gives warning against the use of Gersuny's method, which is as yet not firmly

established as a curative agent. He has made trial of it in one case, and his patient suffered from pulmonary and cerebral embolism of paraffin. While he favors the idea as rational and ideal, he is fearful of its consequences.

Subcutaneous Incision of the Sphincter in Perinæorrhaphy. By Professor Fritsch.

Case of Uterine Myoma Complicated with Diabetes. By Dr. Jahreiss.

January 19, 1901.

Gynæcological Massage.—Professor R. Olshausen says that much evil is done by promiscuous and uncomprehended massage in female pelvic diseases. The only cases which are suitable for massage are the exudates into the pelvic connective tissue when they have run their course and all signs of active inflammation have disappeared. These exudates form suitable cases, too, only when the external hand can reach them, so that only the abdominal parietes lie between the external and internal hands. Tumors of the tube can rarely be successfully massaged, and only when they are hydrosalpingitides whose contents can be brought to discharge themselves through the uterus. Massage of the tubes with thickened walls, without fluid contents, can be productive of good only because the surrounding infiltration yields to the treatment. Peritoneal adhesions, hæmatoceles, displacements of the uterus and vagina are not suitable lesions for massage, even though the massage of the surrounding exudates may occasionally be indirectly useful in displacements.

Pregnancy; Uterine Cancer. By Dr. T. Michalitsch.

January 26, 1901.

Proof of Traces of Bullet Forceps on the Cervix.—Professor R. Chrobak says that his observations have led him to believe that after four days, traces of bullet forceps used in operations are not visible upon a puerperal uterus, while it takes nine days for the puncture wounds to heal upon a non-puerperal uterus. He explains the difference by the greater rapidity of the epithelial growth in the former class. The subject is of forensic importance.

Küstner's Suprapubic Horizontal Incision. By Dr. Fritz Kühne.

Puerperal Gangrene of the Lower Extremities. By Dr. E. Wormser.

Centralblatt für Chirurgie, January 12, 1901.

Treatment of Recent Luxation of the Peronei Tendons.—Dr. H. Reerink reports the case of a man who, while mounting his horse, slipped and dislocated the tendons of the peroneus group of muscles just behind the external malleolus. When the swelling had disappeared, perpendicular strips of zinc adhesive plaster were applied, and these held the tendons securely in place. After a few weeks recovery was perfect.

Simplification of Plastic Achillotomy. By Professor Carl Bayer.

New Operating Table. By Dr. Rathmann.

January 19, 1901.

How to Secure Deep, Regular, Quiet Breathing at the Beginning of Anæsthesia.—Dr. C. Hofmann urges competent assistants as anæsthetizers. He has achieved good results by giving ether by the drop method. To

secure regular, quiet respirations at the beginning of anæsthesia, he instructs his patients to count backwards, beginning at 200, so that the figures are somewhat difficult to pronounce, and to breathe deeply between the pronunciation of each two figures. The counting requires such a concentration of thought that the mind is freed from the contemplation of the operation and mental distraction allows the anæsthetic to be pushed.

New Method of Forming Double Flaps in Plastic Operation on the Cheek. By Dr. F. Neugebauer.

Sterilization of Silk Catheters.—Dr. M. W. Herman recommends the boiling of silk catheters for several hours in a saturated solution of ammonium sulphate. The procedure does not injure the catheters in any way. Boiled from three to five minutes, they are rendered absolutely sterile and may be used at once for catheterization.

Wiener klinische Wochenschrift, January 10, 1901.

Lactic-acid Bacilli.—Dr. Rudolf Schmidt has investigated the flora of the stomach. He says that the bacillus of Boas-Kaufmann (the lactic-acid bacillus) attains a very luxuriant growth on streak cultures from a carcinomatous stomach when blood is added to them; thus the absence of the bacillus in benign processes may be attributed to the absence of blood, which forms an excellent culture medium for it. Other features that aid its growth are, probably, stagnation of the gastric contents, diminished or absent hydrochloric acid, absence of fermentation, presence of albumin and blood from an ulcerating lesion. In carcinomatous stomachs, there may be a profuse growth of colon bacilli with no gastrointestinal fistula.

The Crossed "Sciatic Phenomenon." By Dr. J. Fajirsztajn.

Theories of Cardiac and Renal Disease. By Dr. Otto Gross.

January 17, 1901.

Relations between the Nose and Female Genitals.—Dr. Arthur Schiff accepts the work of Fliess, that the nose contains two so-called "genital spots" situated at the tuberculum septi. During menstruation, these areas become congested, swollen, and very sensitive to gentle touching with the sound. In cases of dysmenorrhœa, these areas are especially sensitive; if they are thoroughly anæsthetized, the pain disappears and the menstrual flow proceeds painlessly. It is important that perfect anæsthesia should be secured, and to this end the author advises the use of twenty-per-cent. solution of cocaine. A mere application to the nose is useless; anæsthesia of the "genital spots" must be secured. This is best accomplished by a visual application of cocaine through a nasal speculum.

Case of Unilateral Diffuse Mammary Hypertrophy.—Dr. Bernard Engländer reports such a case in which the right breast of a woman reached a colossal size.

Phosphorus in Rhachitis.—Professor Monti, in an elaborate clinical paper, says that the phosphorus treatment of rickets dates from the time of Trousseau. The cure of the disease has not yet been established by this method of treatment, especially since experimenters have not yet succeeded in curing the disease in its early stages when it is induced in animals. In spite of the use of phosphorus, the disease advances steadily in man. If beneficial osseous changes take place while phosphorus is being administered, they are rather to be ascribed to

the hygienic measures instituted at the same time. Exact measurements and weights of the body at intervals alone can determine the value of phosphorus as a therapeutic agent.

Centralblatt für innere Medicin, January 12, 1901.

Action of Morphine upon the Stomach.—Dr. Alfred Hirsch deduces from his experimental studies the following conclusions concerning the usual hypodermic doses of morphine given to man: (1) the gastric peristalsis is decidedly diminished; (2) the secretion of hydrochloric acid is at first diminished, later increased; (3) this influence varies with the dose employed and is more pronounced if the drug is given hypodermically than by mouth. The author thinks that the initial inhibition of hydrochloric-acid secretion is evoked by the excretion of the morphine by way of the gastric glands, while the subsequent increased secretion is due to central influences.

Action of Thyreoid Preparations in some Unusual Diseases.—Dr. Arthur Jaenicke reports successful results from the use of thyreoid extract in a case of malignant disease of the mamma, in two cases of lymphoma, and in one of pseudoleukæmia.

January 26, 1901.

Study of Disturbances of Pulmonary Circulation.—Dr. Joseph Esser says that the main causal element of a disturbance of the pulmonary circulation lies in the rigidity of the vessels due to sclerosis, a condition not as rare as is commonly supposed. The rigidity interferes with the work of the right heart as well as with the elastic distension of the alveoli in respiration.

Berliner klinische Wochenschrift, December 31, 1900.

Experimental Studies on Alopecia.—Dr. A. Buschke reports the case of a young woman who was taking one grain and a half of thallium acetate for the night-sweats of phthisis. After a few doses, severe neuralgias appeared in various parts of the body, including the head, and a general alopecia of the scalp then followed. The author succeeded in inducing alopecia in animals by the local and subcutaneous use of thallium. He does not explain the action of the drug.

Agglutinating Substances from Blood-cells in the Urine. By Dr. E. Friedberger.

Severe Spinal Symptom-complex Due to Serpentine Aneurysm (conclusion). By Dr. Felix Brasch.

Simplification of the Phenylhydrazine Test for Sugar. By Dr. A. Neumann.—A polemic article.

Deutsche Medizinal-Zeitung, January 21 and 28, 1901.

Obesity and its Treatment.—Dr. H. Strebel considers all the methods of reducing fat in obese people and gives in minute detail the methods he pursues, a combination of well-known measures. The paper is too full of minutiae to abstract.

Riforma medica, January 2 and 3, 1901.

Traumatic Syringomyelia. By Dr. G. Rummo.—The author reports a case of syringomyelia in a man aged twenty years who gave a history of severe traumatism. In speaking of the treatment, the author says that the first indication is to promote the nutrition and to stimulate the tone of the arteries in the spinal cord. For this purpose cannabis indica, ergot, and belladonna should be used. If there are symptoms of irritation, we must have recourse to belladonna or atropine. The second indication is to promote the nutrition of the centres. For this purpose we may use drugs that are beneficial in

stimulating the functions of the nerve centres, such as iron, phosphorus, and arsenic. Iodide of sodium must be used cautiously, as the iodides promote vasodilatation and oppose the formation of new connective tissue. In some places vasodilatation is beneficial, in others it is injurious. A favorite formula of the author's is as follows:

		Grammes.	
℞	Pyrophosphate of iron and sodium.....	4.0	1 drachm;
	Phosphate of zinc.....	0.06	1 grain;
	Calcium glycerophosphate.....	10.0	2½ drachms;
	Sodium arsenite.....	0.01	¼th of a grain;
	Hydro-alcoholic extract of ergot,		
	Extract of nuxvomica,	} of each. 2.0	½ an ounce;
	Extract of cinchona,		
	Extract of coca,	} of each. 3.0	45 grains.
Make 120 pills, and give one three times daily.			

January 4 and 5, 1901.

On the Possibility of a Return Flow of Urine from the Bladder into the Ureters. By Dr. Filiberto Iacobelli:—A series of experiments on animals, undertaken with a view of determining the very interesting question as to the mechanism of renal infection as the result of cystitis, etc., leads the author to the following conclusions: The chief defense of the kidney and ureters is the current of urine that issues continuously from the pelvis of the kidney. So long as this current flows with normal intensity, there is but little chance of renal infection. If, however, this current is interrupted, *e. g.*, by an obstruction above the bladder, or if it is impeded by an overfilling of the bladder (retention), bacteria easily reach the kidney. The author has experimented with the *Bacillus pyocyaneus* only, but will continue his researches in the same line, and hopes to be able to show that other bacteria act in the same way. The influence of urinary retention upon renal infection is therefore really indirect, and not, as has been heretofore taught, direct and due to backward flow of urine.

January 7 and 8, 1901.

Resection of a Portion of the Liver for Syphiloma. By Dr. E. Tricomi.—In 1889 the author published an account of five partial hepatectomies (two for adenoma, two for syphiloma, and one for echinococcus cysts). He adds another case in which he performed this operation for a syphilitic tumor. The patient was a man aged thirty-six years, who had the primary syphilitic ulcer at the age of twenty years, but who denied the occurrence of secondary symptoms. Six years ago, without apparent cause, he was seized with a sudden intense pain in the right hypochondriac region, radiating to the right shoulder. A blister was applied, and the pain gradually disappeared in two days. Three years ago he had a second attack of this kind, which was followed by a third within two weeks, and by a fourth within a month. Ten months before admission he had a fifth attack of extraordinary severity, and during this paroxysm he noticed a swelling at the site of the pain. At first this swelling was small, but it grew until it reached its present size. During the last ten months the patient had had six attacks of severe pain in the same region, accompanied by vomiting. A slight jaundice followed each attack. He

and constipation alternating with diarrhoea, but no calculi were passed in the fæces. On examination, no syphilitic manifestations were found externally. The swelling was found to be of the size of an adult's fist, hard, elastic, smooth, movable laterally and from below upward, but not from above downward. The tumor moved with the respiration and extended below the level of the umbilicus, internally to the parasternal line, externally to a line drawn through a point two fingerbreadths outside of the nipple. There was slight jaundice. The diagnosis was uncertain between syphiloma and biliary calculi. An exploratory operation was performed. The incision was oblique, parallel to the margin of the ribs, and two fingerbreadths away from this margin, beginning at the outer border of the rectus and ending at the prolongation of the anterior axillary line. A reddish-gray tumor situated on the right lobe of the liver was discovered as soon as the peritonæum was opened. The gall-bladder was normal. The tumor was not adherent to the intestines, was pyriform in shape, attached to the hepatic margin by a pedicle, and was slightly nodular in character. As the anæsthesia did not proceed favorably, the author decided to remove the tumor in two operations. He tied the pedicle with a rubber tube and sewed the liver capsule to the peritonæum. The hepatic tissue around the pedicle tore somewhat when the tube was drawn tight, but the hæmorrhage was slight. Eight days later the cutaneous sutures were removed, and ten days later the tumor and the adjoining portion of liver were found almost detached from the rest of the organ, and the separation was completed with scissors. While the patient remained in the clinic he received antisiphilitic treatment. He was discharged on the thirty-fifth day.

January 10, 1901.

Histologic Researches Concerning the Modifications in the Organs of Hibernating Mammals. By Dr. Luigi Baroncini and Dr. Arturo Beretta.—This is the third of a series of articles dealing with the subject, the two others having been abstracted in this column of this journal for May 26, 1900, p. 834, and August 18, 1900, p. 301. In the present article the authors take up the consideration of the changes in the suprarenal capsule during hibernation. They have found that there is a progressive diminution of the fat which is deposited in various parts of the organ at the beginning of hibernation. There is also a cloudy swelling of the whole gland, and in the cells a small corpuscle, having all the characteristics of a nucleolus, appears, while the nucleolus itself can no longer be demonstrated after hibernation.

January 11 and 12, 1901.

Concerning the Limitations of the Elastic Bandage in Surgery. By Dr. Guido Turazza and Dr. Gioacchino Avesani.—A report of a series of surgical operations, including various amputations, etc., performed with the aid of the Esmarch bandage. The discovery of the principle of elastic compression as represented by the Esmarch bandage is credited to an Italian, Grandesso-Silvestri.

Roussky Archiv Patologiyi, Klinitcheskoy Meditsiny i Bakteriologiyi, November, 1900 (Russian Archives of Pathology, Clinical Medicine and Bacteriology).

The Influence of the Fæces on the Blood. By Dr. F. Borodouline.—While it is well known that the gastrointestinal tract is a laboratory in which are formed certain products of decomposition, which, if retained, may

give rise to pronounced morbid phenomena, such as headache, vomiting, vertigo, etc., it is by no means clearly evident as yet in what way these excrementitious products act upon the blood. The author has studied this question experimentally by injecting solutions of fæcal material into rabbits and dogs, the fæces always being taken from the same species of animals as those into which the solution was injected. The solutions were prepared with water, alcohol, or ether, or with a mixture of alcohol, water, and ether. The watery solution was prepared as follows: One gramme of fresh fæces was mixed daily with ten cubic centimetres of distilled water and carefully rubbed with a glass rod, allowed to stand for one hour and a half, filtered through a double filter, the filtrate evaporated on a water-bath, and the residue dissolved in five cubic centimetres of water, boiled, and injected. The ethereal solution was prepared by adding eight cubic centimetres of ether to two grammes of fresh fæces, mixing for five minutes, filtering, allowing to stand until the ether had evaporated, and dissolving the residue in five cubic centimetres of water, boiling, rubbing once more with a glass rod, and injecting. The alcoholic extract was prepared by adding ten cubic centimetres of alcohol (92°) to four grammes of fresh fæces, mixing, allowing to stand for one hour, filtering, evaporating the filtrate, dissolving the residue in five cubic centimetres of water, boiling, and injecting. The extract prepared with a mixture of ether, alcohol, and water was obtained as follows: The fæces (200 grammes) were first dried at 100° C. for an hour, then 600 cubic centimetres of ether were added, the dried fæces rubbed up, and allowed to stand for twenty-four hours in a closed vessel. The solution was then filtered through a double filter, and allowed to stand until the ether had evaporated. The residue on the filter was extracted with alcohol and filtered, and the residue of the second filtration was extracted with water. The three extracts were then mixed and injected into the animal. The author gives a full account of his experiments and observations. The latter may be summed up as follows: If we consider what constituents of fæces are soluble in water, alcohol, or ether, we find that only a small percentage of the constituents are so soluble, and yet all products of bacterial life and of decomposition are soluble in one of these solvents. Thus, water dissolves phenol, cresol, and all the allied derivatives, and also the fatty acids with low amounts of carbon, the amines, leucine, and some of the ptomaines. All these substances affect the blood when introduced into the circulation. Thus the phenols will produce pernicious anæmia. It may therefore be assumed that a part of the effects of the injection of fæces into the blood is due to the phenols and their derivatives, and to the amines. The substances which are dissolved by alcohol produce such unimportant effects that they need not be considered, except, perhaps, the effect of a portion of the phenol which is soluble in alcohol. On the other hand, the substances dissolved in ether belong to the most poisonous constituents of the fæces. Such, for example, are excretin, liquid ptomaines, etc. Which of these substances produces the changes observed in the blood of the animals tested, the author cannot say. He concludes as follows. 1. Aqueous extracts of fæces injected in small doses into animals will produce pernicious anæmia. 2. Alcoholic extracts of fæces under the same conditions will produce a mild anæmia. 3. Ethereal solutions will produce an anæmia not so severe as that caused by aqueous extracts, but, in addition, there will be hæmor-

rhages in various organs. 4. Extracts prepared with ether, alcohol, and water, will produce pernicious anæmia and hæmorrhages. The clinical deduction is that in man a certain number of idiopathic anæmias depend upon self-intoxication as the result of absorption of products of decomposition from the intestine. Under normal conditions the products of intestinal decomposition go to the liver after having been absorbed by the portal vein. In the liver they are changed and become harmless; but if an excess of these substances is absorbed, as in constipation, the liver cannot take care of them, and they reach the blood in an unchanged state.

The Diagnosis of Acute Inflammations of the Spinal Cord. By Dr. V. A. Mouratoff.—The author reports two cases of acute myelitis presenting some interesting features, and takes these cases as a text for a discussion of the diagnosis of acute inflammatory processes in the cord. His conclusions are as follows: 1. The parenchymatous changes in the fibres and cells do not depend on lesions of the blood-vessels—on the contrary, they are primary, and due to toxic causes. 2. One may distinguish three forms of acute myelitis according to the clinical features and the results of the autopsies: (a) Acute hæmorrhagic myelitis. This is manifested by a sudden onset and irreparable symptoms due to mechanical pressure. (b) Acute interstitial myelitis, accompanied by various sets of symptoms, some temporary, others permanent. These two forms may exist as focal or disseminated myelitis (Westphal's type). The first is manifested by a sudden onset and localized symptoms; the second by a sudden onset, by remissions, and by the appearance of new sets of symptoms indicating dissemination. (c) Diffuse parenchymatous myelitis, characterized by an ascending or descending progression. It is distinguished from polyneuritis by the segmentary character of the symptoms. In polyneuritis the symptoms are localized in certain nerves. 3. Lesions of the spinal cord complicating Landry's paralysis are not always "medullary," as Leyden states; a true parenchymatous myelitis may be found in this disease.

Concerning Fragmentation and Brown Atrophy of the Heart Muscle. By Dr. V. A. Taranouchine.—The author has found the following lesions in the heart of a man aged sixty-five years who had died suddenly without any apparent cause: Sclerosis of the coronary artery; diffuse myocarditis; fatty degeneration of the cardiac muscle; marked fragmentation of the muscular tissue, and brown atrophy of the muscles of the heart, with the usual disposition of the pigment near the poles of the nuclei, as well as with bead-like masses between the fibres. He has studied the last two changes in detail, and draws the following conclusions as to fragmentation and brown atrophy in the heart muscle. 1. In view of the coexistence of marked narrowing of the coronary artery and of acute fatty, pigmentary, and sarcolytic degeneration, together with diffuse myocarditis, it may be said that the fragmentation of the cardiac muscle fibre is a complex phenomenon. It depends on an acute and a chronic process. The former is simple fragmentation, due, perhaps, to a strong vicarious contraction of the previously torn fibres during the death agony; the latter is the fragmentation that takes place as a result of sarcolytic changes in the muscle, due to malnutrition, developing slowly, and capable of producing myofibrosis. As regards the origin of the pigment, all the author's observations speak in favor of an albuminogenous nature of the pigment. The method of formation of this pigment is left to further investigations, but the author

calls attention to the rarity of the arrangement of the pigment which he has observed—the bead-like rows of granules between the fibrils of muscle tissue.

Concerning Artificial Cultures of the Germ of Leprosy. By Dr. V. I. Kedrovsky.—The attempts of numerous investigators who have experimented with the bacillus of leprosy with the intention of producing artificial cultures of this germ, have not been particularly successful, and the author took the opportunity of investigating the cultural peculiarities of this germ in three cases of leprosy which he had at his disposal. His experiments included a number of attempts at cultivation and staining, and the results may be summed up in the following conclusions: 1. The germs of leprosy suffer a number of alterations in their characteristics when grown outside of the body. 2. Babes classes them as members of the diphtheroid group, and styles them diphtherideæ, on account of their morphologic features. A more complete acquaintance with their biology, as the result of the observations of the author and of Barannikoff, shows that they should be classed in the group of ramifying germs, which has been until now known by the somewhat confusing terms *streptothrix*, *cladotrix*, *actinomyces*, etc. It is possible, however, that there is no considerable difference between the groups diphtherideæ and cladotrix, and that further study will show both groups to be members of the same class. 3. In artificial cultures, the bacilli of leprosy retain their power of resistance to acids in exceptional cases only. In the majority of cases this resistance is lowered, or is retained only in a certain stage of development, or, finally, this resistance may be present only in a part of the organism (metachromatic granules of Babes). 4. In some cases the germs are cultivated easily on artificial media; in others this is impossible or only feasible with great difficulty. The author used a medium which he had devised for the purpose of cultivating the lepra bacillus under the most favorable conditions of nutrition. This new medium is prepared as follows: A freshly expelled human placenta is finely chopped in a meat-chopping machine and is extracted for from eighteen to twenty-four hours in from one part and a half to three parts of distilled water. The resulting dark-red, thick fluid is passed through a filter and sterilized. The amount of water depends upon the quality of the placenta itself. The more full-blooded and rich in nutritious tissues the latter is, the less of it will be required for the culture medium. The filtration should be carried on slowly but accurately in a Chamberland filter. The medium is then poured into sterile tubes and may be kept for a considerable time without altering its nutritive value, although after a few weeks it may become brownish in color.

Concerning the Pollution of Streams by Sewage and the Measures to be Adopted for the Purpose of Removing the Latter. By Dr. G. V. Chlopine.—The author's conclusions, based on an extensive study of the subject, are as follows: 1. The most perfect method of purifying sewage is by subsoil irrigation of fields with the impure water. 2. Simple or periodic filtration does not give satisfactory results. 3. The so-called biological methods are better than the various modes of filtration. 4. Chemical purification, with subsequent sedimentation or filtration, removes principally the mechanical impurities, and affects the substances in solution but little. It is not cheaper than subsoil irrigation. 5. The methods of purification by means of the electric current are still in the experimental stage.

Letters to the Editor.

LEGISLATIVE RESTRICTION OF THE RIGHT TO PRACTISE.

103 STATE STREET, CHICAGO, February 12, 1901.

To the Editor of the *New York Medical Journal*:

SIR: While attending the meeting of the Medical Society of the State of New York, I was much interested in the hearing before the Senate committee upon the so-called Bell bill, upon which you comment in your last issue. In the State of Illinois we have recently gone through a rather trying period in amending our medical practice act so as to secure a State examination. Illinois was one of the first States to have a medical practice act, but it placed the power of regulating things in the hands of the State board of health and authorized them to accept diplomas from medical colleges in "good standing" as an evidence of fitness to practise. This rule prevailed for over twenty-five years. Finally the term "good standing" became so elastic as to practically cover any diploma mill that might be started. In the effort to change the law, it became necessary to draft an entirely new statute, although it was felt by the committee in charge that the main thing was to secure the examination. Many of the profession insisted upon having a medical practice act drawn somewhat on the lines of your proposed bill, which so restricted personal liberty as to make most of the provisions unconstitutional. Any statute that goes too far in this direction nullifies itself.

The difficulty in Assembly bill No. 167 is in defining the practice of medicine, and this will always be a stumbling-block. The definition adopted in the Illinois act is very simple; it states that it shall be simply the operating on, prescribing for, or giving of a material remedy to any one afflicted, with the usual exceptions relating to the army and navy and the domestic administration of remedies. It also excepts the treatment of disease by mental or spiritual means, thus taking the Christian Scientist from among those who practise medicine.

After this legislation had been secured and the matter had been thoroughly discussed in all its bearings, the committee was convinced that it would have been better to omit all definition of the practice of medicine. There is a well-defined idea in the community as to what the words "practising medicine" mean, and it is by no means certain that it is necessary to define the practice of medicine in a medical practice act, but it can safely be left to the judges and jurors, to be applied to the circumstances as they arise in particular cases. One of our judges, in construing the medical practice act of Illinois, convicted a "divine healer" who admitted that he cured a patient by the laying on of hands. It was the latter procedure which, the judge said, brought it within the limitations of the act. Had he not resorted to physical means, but had simply used prayer or exhortation, he would have been exempt.

It is doubtful if any statute can be devised that will prevent an individual from employing a man to pray his diseases away or to sit with his back to him and instruct him to think that there is nothing the matter with him. It is the inalienable right of every American citizen, guaranteed by the Constitution, to make a fool of himself if he wishes to. The danger to the public health and to the community at large is that the so-called Christian Scientists, faith healers, and other quackish pretenders will be regarded as practitioners of medicine

and receive a quasi-public recognition as such. If this can be prevented, about all that can be accomplished in the way of legislation will have been done. Therefore, a law which simply states that the practice of medicine shall not be undertaken by those who lack qualification is about as far as legislation can go.

There is a possibility that all the medical practice acts of the United States are somewhat defective in having started on a wrong principle. In attempting to restrict an occupation, there are always the difficulties of constructing a definition and of interference with individual liberty, but the principle of copyright might easily have been employed. The letters R. P., meaning registered practitioner, or M. D., or some similar title, might be employed to arbitrarily designate one who is qualified for the practice of medicine. This would operate as notice to the public that all others did not have the necessary legal qualifications, and hence were practising medicine illegally. Certain penalties could be inflicted upon those attempting to practise who were not registered, and for the unauthorized use of the designation. Such a law would be simple and easy to enforce. Any attempt to bring the ordinary usages of Christian Science within the meaning and limitations of a medical practice act is almost certain to fail.

HAROLD N. MOYER, M. D.

ELECTRICITY IN GOÎTRE.

25 SOUTH WILLIAM STREET,
JOHNSTOWN, N. Y., November 17, 1900.

To the Editor of the *New York Medical Journal*:

SIR: In looking over your valuable *Journal*, as is my weekly custom, I noticed an article by Dr. H. B. Anderson entitled Sudden Death in Goître, in the issue for November 10, 1900, on page 830, taken from the *Canada Lancet* for October. I must confess that, to me, the article appears of no little significance. There are so many factors of such signal importance and interest mentioned that a short review would not be unprofitable, since at the present day many diseases are treated by electricity with marked benefit.

If I may judge from my own experience, in no single disease are better results obtained than in the one under consideration, namely, goître. I am confident, however, that, in order to obtain the best possible results and to be positively free from any and all danger, a properly selected instrument, as well as a competent electrician, is absolutely and positively essential. I speak from that knowledge which is gained only by experience, and I have had considerable experience in the treatment of exophthalmic goître, not a single patient having thus far failed to respond in my hands kindly and satisfactorily to electrical treatment, and no untoward results having been observed. But I am digressing, perhaps, and will return to the subject.

I desire to consider the factors reported in this case. In the first place, I will say that the case, as reported by Dr. Anderson, certainly has many features resembling those found in cases in which the cause of death was known to have been by lightning or electric shock, for *post-mortem* examination of a body after a lethal shock will reveal similar conditions, and the results are the same, whether the lethal shock is received from the heavens or from the Leyden jar. The investigation made at the Polytechnic Institute by Dr. B. Ward Richardson (*Medical Times and Gazette*, May 15, 1869, and May 11,

1870; also Tidy's *Legal Medicine*, Vol. ii, 1882) shows that several kinds of sparks are obtained under different conditions, and that their discharge differs in effect, some expending their force on voluntary motion and common sensation, and these are not fatal; others on respiration and circulation, and these are fatal.

Dr. Anderson states, in regard to symptoms observed prior to the unfortunate and sad termination in death, that, on the application of the electrodes, while the patient was speaking, she was seized with spasmodic cough and choking, that the respiration became gasping and stridulous, and that the face was livid. If we consider these symptoms and make any deductions as to their probable cause, the most tenable explanation would suggest irritation of the recurrent laryngeal nerve, followed by spasmodic closure of the epiglottis, and resulting in asphyxia with accompanying loss of consciousness, interrupted respiration, suffocation, and enfeeblement and impairment (possibly with stoppage) of the heart's action.

What caused this? would be a natural question, but I do not feel justified at this distance in answering it; neither would it be wise or proper to say how much, if any, of this condition should be charged to the electrical current, for the current applied was to some extent an indefinite quantity. Dr. Anderson states that it was less than twenty milliamperes; how much less he does not say, nor does he say with what kind of meter the current was measured, what current-controller was interposed, or how suddenly the full strength of the current that was used was turned on. My experience leads me to believe that few persons will tolerate even half the quantity supposed to have been used, when measured by a Weston meter, if the electrodes are applied in the region of the neck and throat in such close proximity to the large blood-vessels and important nerves. In the cases that have come under my observation I have begun with one milliamperè and increased gradually to possibly five or six. Seldom, however, will a patient tolerate over two or three without exciting a cough vertigo.

In this case all the indications of asphyxia were present, such as the livid face before death; the dark, reddish color of the tissues; the color of the fluids that escaped from the incision; the dark-colored blood clots; the distended veins of the neck; the frothy, reddish-colored mucus in the trachea; the congestion of its membranes, and the facts that the lungs were normal, save for the hypostatic congestion at the base; the right side of the heart was full of dark fluid blood, and the left side contracted and empty. How far these conditions indicate the cause of death may be problematical. Yet, is it unfair to say that, when like conditions are observed in *post-mortem* examinations made on persons positively known to have received lethal doses of electricity, either by lightning or by the battery, the strength of the current reported by Dr. Anderson as having been used by him may have been an important factor in inducing the conditions observed, even though other factors and conditions may have been the real cause of death?

Another factor to be considered is the general condition of persons who have goitre. We find them weak and enfeebled in some one direction, if not in all. Generally neurasthenia is marked, and tachycardia and tremor, first described by Bascdow, are always present. Associated with this is a condition or feature noted by Charcot, namely, the general diminution in electrical resistance, believed to be due to the saturation of the skin with moisture, owing to the vasomotor dilatation. Owing

to this covering of resistance, a small electromotive force is sufficient to give the required strength of current (Jones, *Medical Electricity*, 3d edition, 1900). The number of cells in the circuit must, therefore, be small, beginning with as few as three or four, and the galvanometer reading must be carefully attended to. Cardew (*Lancet*, July, 1891) says that a current of two or three milliamperes should be applied for six minutes. Jones (*Medical Electricity*, page 267) says that for most forms of local treatment five milliamperes are sufficient, and that this amount may be too much for a child or a sensitive person. When the applications are made to the head or neck, additional care must be exercised, the effect upon the brain being peculiar and unpleasant. Liebig and Rhoe, page 282, allude to weak currents ($\frac{1}{40}$ to $\frac{1}{20}$) and short sittings. Davis (*International System of Electrotherapeutics*) states that a weak galvanic current is usually applied over the cervical ganglia.

In presenting these thoughts on this case I am not actuated by a desire to question the treatment employed by Dr. Anderson, or the results, or the cause of death; I desire only to caution those who employ electricity in the treatment of disease that suitable instruments, mild currents, and proper qualifications are a *sine qua non*.

JEHIEL LEFLER, M. D.

Miscellany.

Information for Candidates Seeking Appointment in the Medical Corps of the United States Army.—The surgeon-general has issued the following circular, dated February 4th: The medical corps of the army, as increased from a total of one hundred and ninety-two to three hundred and twenty-one medical officers by recent Congressional action, consists of a surgeon-general with the rank of brigadier-general, eight assistant surgeon-generals with the rank of colonel, twelve deputy surgeon-generals with the rank of lieutenant-colonel, sixty surgeons with the rank of major, and two hundred and forty assistant surgeons with the rank of first lieutenant, mounted, for the first five years, and the rank of captain, mounted, thereafter, until promoted to major.

Section 1172, Revised Statutes of the United States, provides that "No person shall receive the appointment of assistant surgeon unless he shall have been examined and approved by an army medical board, consisting of three surgeons or assistant surgeons, designated by the Secretary of War; and no person shall receive the appointment of surgeon unless he shall have served at least five years as an assistant surgeon in the regular army, and shall have been examined and approved by an army medical board, consisting of not less than three surgeons, designated as aforesaid." The act to increase the efficiency of the military establishment of the United States, recently approved, further provides "that the period during which any assistant surgeon shall have served as a surgeon or assistant surgeon in the volunteer army during the war with Spain or since shall be counted as a portion of the five years' service required to entitle him to the rank of captain.

All vacancies are filled by appointment to the junior grade (first lieutenant). Promotion through the intermediate grades of rank from that of captain to that of colonel is by seniority, but there is an examination for the rank of captain and another for that of major, to

ascertain the fitness of the officer for promotion. Advancement to lieutenant-colonel and colonel takes place without further examination. The surgeon-general is selected by the President from among the members of the corps.

Pay and Emoluments.—To each rank is attached a fixed annual salary, which is received in monthly payments, and this is increased by ten per cent. for each period of five years' service until a maximum of forty per cent. is reached. An assistant surgeon with the rank of first lieutenant, mounted, receives \$1,600 per annum, or \$133.33 monthly. At the end of five years he is promoted to captain and receives \$2,000 a year, which, with the increase of ten per cent. for five years' service, is \$2,200, or 183.33 per month. After ten years' service as captain the pay would be \$2,400 annually, or \$200 per month. The pay attached to the rank of major is \$2,500 a year, which, with ten per cent. added for each five years' service, becomes \$3,000 after ten years' service, \$3,250 after fifteen years, and \$3,500 after twenty years. The monthly pay of lieutenant-colonel, colonel, and brigadier-general is \$333.33, \$375, and \$458.33, respectively. Officers, in addition to their pay proper, are furnished with a liberal allowance of quarters according to rank, either in kind, or, where no suitable government building is available, by commutation. When traveling on duty an officer receives mileage for the distance traveled; the amount allowed is sufficient to cover all expenses of journey. On change of station he is entitled to transportation for professional books and papers and a reasonable amount of baggage at government expense. Mounted officers, including all officers of the medical corps, are provided with forage, stabling, and transportation for horses owned and actually kept by them, not exceeding two for all ranks below a brigadier. Groceries and other articles may be purchased from the commissary, and fuel from the quartermaster's department at about wholesale cost price. Instruments and appliances are supplied in abundance for the use of medical officers in the performance of their duties. Well-selected professional libraries are supplied to each hospital and standard modern publications on medical and surgical subjects are added from time to time; current issues of a number of representative medical journals are also furnished for use of medical officers.

Army Medical School.—In 1893 the Secretary of War authorized the establishment of an Army Medical School in the city of Washington for the purpose of instructing medical officers who have been appointed since the last preceding term of the school, and such others as may be authorized to attend. The course of instruction is for five months, and will be given annually, when practicable, at the Army Medical Museum, in Washington City, commencing in November. Five professors are selected from among the senior medical officers of the army, stationed in or near the city of Washington, also an instructor in first aid and ambulance drill.

The faculty of the Army Medical School consists of: 1. A president of the faculty, who is responsible for the discipline of the school, and who delivers a course of lectures upon the duties of medical officers in war and peace (including property responsibility, examination of recruits, certificates of disability, reports, rights and privileges, customs of service, etc.). 2. A professor of military surgery (including the care and transportation of wounded and operative surgery). 3. A professor of military hygiene (including practical instruction in the examination of air, water, food, and clothing from a

sanitary point of view). 4. A professor of military medicine. 5. A professor of clinical and sanitary microscopy (including bacteriology and urinalogy).

Duties and Privileges.—Leave of absence on full pay is allowed at the rate of one month per year, and this, when not taken, may accumulate to a maximum of four months, which at the end of four years is then available as one continuous leave. Beyond this, an officer may still be absent with permission on half pay. Absence from duty on account of sickness involves no loss of pay. Medical officers are entitled to the privilege of retirement at any time for disability incurred in the line of duty, or after forty years' service. On attaining the age of sixty-four they are placed upon the retired list by virtue of law. Retired officers receive three fourths the amount of their pay proper at the time of retirement. When medical officers with the rank of captain approach the period of their examination for promotion to a majority they are usually assigned to duty as attending surgeons in the principal medical centres of the United States, to enable them to become familiar with the practice of the leading physicians and surgeons in this country, and to attend medical lectures, meetings of medical societies, etc. These assignments are made for one year only, in order that as many medical officers as possible may be enabled to avail themselves of the advantages thereby afforded. At the end of this tour of duty they are required to make a detailed report to the surgeon-general showing how much of their time has been occupied by their official duties and to what extent they have availed themselves of the advantages offered for professional advancement.

Examination and Appointment.—Appointments to the medical corps of the army are made by the President after the applicant has passed a successful examination before the army medical examining board and has been recommended by the surgeon-general. Due notice of the meeting of the board is published in the medical journals. Permission to appear before the board is obtained by letter to the Secretary of War, which must be in the handwriting of the applicant, giving the date and place of his birth and the place and State of which he is a permanent resident, and inclosing certificates, based on personal acquaintance, from at least two reputable persons as to his citizenship, character, and habits. The candidate must be a citizen of the United States, between twenty-two and twenty-nine years of age, in the case of a candidate applying for appointment from civil life, and between twenty-two and thirty-four years of age in the case of a candidate who has served honorably in the army of the United States, either as a commissioned medical officer of volunteers or as an acting assistant surgeon during the war with Spain or since. He must be of sound health and good character, and a graduate of some regular medical college, in evidence of which his diploma will be submitted to the board. The scope of the examination includes the morals, habits, physical and mental qualifications of a candidate, and his general aptitude for service; and the board will report unfavorably should it have a reasonable doubt of his efficiency in any of these particulars.

The physical examination comes first in order, and must be thorough. Candidates who fall below sixty-four inches in height will be rejected. Each candidate is also required to certify "that he labors under no mental or physical infirmity or disability which can interfere with the efficient discharge of any duty which may be required." Errors of refraction, when not excessive, and

not accompanied by ocular disease, and when correctible by appropriate glasses, are not causes for rejection.

The professional examinations are conducted by both written and oral questions, upon anatomy, physiology, chemistry, hygiene, pathology and bacteriology, therapeutics and materia medica, surgery, practice of medicine, obstetrics and the diseases of women and children. Examinations are also conducted at the bedside in clinical medicine and surgery, and operations and demonstrations are required to be made by the candidate upon the cadaver.

Hospital training and practical experience in the practice of medicine, surgery, and obstetrics are essential to candidates seeking admission to the medical corps of the army, who will be expected to present evidence that they have had at least one year's hospital experience, or the equivalent of this in practice.

Candidates presenting a degree in arts, sciences (other than medicine), or literature, those who hold first-class teachers' certificates or who submit evidence of graduation from a reputable high school or similar institution (approved by the board) will not usually be examined in other than the professional subjects enumerated above. Should a candidate, during his professional examination by the board, present evidence of a deficiency in his general education in elementary subjects, he may be required to undergo an oral examination in arithmetic, history, geography, literature, and physics, and such examination, if unsatisfactory, will be cause for his rejection.

Candidates claiming special knowledge of the higher mathematics, ancient or modern languages, drawing, analytical chemistry, or branches of natural science, will be examined in those subjects as accomplishments and will receive due credit therefor according to their proficiency.

To save unnecessary expense to a candidate desiring a preliminary physical examination, written authority may be given by this office for him to present himself at the nearest military post, garrison, or recruiting station for such examination. Any opinion given as to the result of such preliminary examination must, however, be considered as purely advisory and not as determining the subsequent action of an army medical board in the case.

The merits of the candidates in each of the several branches, and also their relative merit as evinced by the results obtained from the entire examination, will be reported by the board, and in accordance with this report approved candidates are appointed to existing vacancies or to such as may occur within two years thereafter. An applicant failing in one examination may be allowed a second after one year, but not a third. No concession can be made for the expenses of persons undergoing examination, but those who receive appointments will be entitled to travel allowances in obeying the first order assigning them to duty.

As a result of the large increase of the medical corps recently authorized by Congress, there are now one hundred and twenty-three vacancies; medical men desiring to enter the military service have therefore an unusual opportunity for so doing. Candidates should at once place on file in this office such papers as are required by the terms of this circular. Successful candidates who have had previous service either as commissioned medical officers or as acting assistant surgeons, will have precedence in appointment over those without previous service.

To illustrate the general character of written ques-

tions submitted to candidates under examination, a few examples from the records of an army medical examining board recently convened are hereto appended.

EXAMPLES OF WRITTEN QUESTIONS.

Anatomy.—1. Describe the origin, insertion, and action of the several muscles attached to the scapula. 2. Describe the origin, course, branches, distribution, and relations to other organs of the nerves of the arm and forearm. 3. Describe the anatomy of the palm of the hand. 4. Describe the origin, course, branches, distribution, and relation to other organs of the internal pudic artery. 5. Describe the anatomy of the ankle joint.

Physiology.—1. Tell what you know about the cerebral localization of the functions of motion and locate some of the so-called motor areas. 2. What are the functions of the thyroid gland and the consequences of its removal? 3. What is the composition of atmospheric air and of expired air? 4. Give a list and a short description of some of the animal albuminoids. 5. What is urea? What is the normal quantity in proportion to body weight? How is it estimated?

Surgery.—1. Give in detail the preparatory and several following steps of a so-called aseptic surgical operation. 2. What is the nature and origin of pus? What is sepsis and also antisepsis? 3. Describe Chopart's amputation through the foot, with diagram. 4. Give the points of diagnostic differentiation in cases of lupous ulceration, syphilitic ulceration, and epitheliomatous ulceration. 5. Describe the different methods of procedure for the reduction of luxations of the head of the femur.

Hygiene.—1. What is the normal amount of CO₂ in the atmosphere, how much of this gas is considered admissible in inhabited apartments, and how is the amount determined? 2. What amount of cubic air space per bed would you consider a suitable allowance in a hospital ward? 3. What substances in well or river water indicate, by their presence, contamination from excreta or other organic matter of animal origin? 4. How is the hardness of water estimated and to what is it due? 5. What are the constituent alimentary substances in milk, and how does cow's milk differ from human milk? 6. What vegetable products used as food contain the largest proportion of carbohydrates and what the largest proportion of proteids? 7. What parasites dangerous to man may be present in the flesh of animals used as food? 8. How would you disinfect the excreta of patients sick with cholera or typhoid fever?

Obstetrics and Diseases of Women and Children.—1. Describe briefly the usual mechanism of a breech presentation; what dangers are to be guarded against and what difficulties to be met? 2. Under what circumstances is premature delivery demanded and how would you perform it? 3. What symptoms would lead you to suspect the presence of a uterine fibroid? State how an exact diagnosis can be made in such cases. 4. What measures, preventive or remedial, would you use in a case of puerperal convulsions? 5. What early symptoms indicate probable onset of the chief eruptive fevers in children? In which does temperature range highest, which has the shortest period of incubation, of invasion, of eruption?

Pathology and Bacteriology.—1. What are the different stages of exudative inflammation and what the products of such inflammation? 2. What are the causes of thrombosis, what the composition and varieties of thrombi, and what changes may they undergo? 3. What pathological changes are found in the spinal cord in posterior spinal sclerosis? 4. What changes occur in the

liver as a result of chronic interstitial hepatitis? 5. What bacteria are commonly found attached to the diseased valves in mycotic endocarditis? 6. What are the morphological and biological characters of the bacillus of diphtheria, and what are the evidences of its aetiological relation to this disease?

Therapeutics, Materia Medica, Toxicology.—1. By what various agents may antipyresis be produced? Give an example of each class of antipyretics and state how it acts. 2. In a case of typical acute pleurisy, state the indications for treatment in its several stages and how you would meet them. 3. What is salol? Give its physiological action and therapeutic uses. 4. Give the source and therapeutic uses of cocaine, the dose in each case, and its dangerous effects. 5. With what condition is poisoning from opium most likely to be confounded? How would you make a diagnosis and how treat such a case? 6. What are the poisonous effects of the lead salts? How is their presence detected? State briefly your plan of treatment.

Practice of Medicine.—1. Give an account of the aetiology, symptoms, physical signs, and differential diagnosis of lobular pneumonia. 2. Give an account of the aetiology, physical signs, and treatment of empyema. 3. Give an account of the aetiology, symptoms, differential diagnosis, and treatment of dilatation of the stomach. 4. What are the causes and symptoms of intestinal obstruction and what is the treatment? 5. What are the causes and results of mitral stenosis, and how would you recognize this condition? 6. Give the differential diagnosis between small-pox and measles.

Chemistry.—1. How may hydrogen be obtained? State its color and odor, and its weight as compared with an equal volume of atmospheric air under similar conditions. What is meant by "similar conditions" in the last sentence? 2. How would you obtain a jarful of carbon dioxide for experimental purposes? How would you recognize that the jar contained carbon dioxide? What is its chemical formula?—its molecular weight? 3. What is that which is known popularly under the name of "laughing gas"? What is its formula? How is it prepared? 4. What is an anhydride? Give the names and chemical formulas of two anhydrides? 5. How is sal ammoniac prepared commercially? 6. What chemical action takes place when copper turnings are heated with sulphuric acid? 7. What are the principal ores of zinc? What is the formula for zinc chloride?—for zinc sulphate? 8. What is glycerin chemically? 9. Explain the chemical action which takes place when gunpowder is exploded.

Carious Teeth as a Cause of Remote Septic Infection.—Dr. William Hunter (*Clinical Journal*, September 12, 1900), in a clinical lecture on Oral Sepsis as a Cause of Disease, with Illustrative Cases, delivered at Charing Cross Hospital, said:

"With regard to the treatment of these cases, what we want recognized on the part of all physicians, surgeons, dental surgeons, and patients, is the septic nature of this condition of caries of the mouth. The gastric trouble is not the result of any dyspeptic trouble, or of ill-health, or of insufficient mastication; but is the result of sepsis caused by the carious teeth.

"The matter, however, is important not only from the point of view of the gastric trouble, but of the infections in the body generally, caused by pathogenic organisms *locally*, acute and chronic tonsillitis, pharyngitis, otitis, follicular abscesses, glandular swellings in

the neck in connection with diseased teeth; or more *remotely*, as ulcerative endocarditis, meningitis, obscure septicæmia complicated by purpuric hæmorrhages, pyæmia, osteomyelitis—in fact, the whole series of conditions caused by pus organisms. The chief problem with regard to these conditions is to find out where the pus organisms have gained entrance. They are not ubiquitous, but are definite organisms causing pus formations. We take most elaborate precautions to ensure ourselves against typhoid infection, either from drains or from water, and we take great precautions to protect ourselves from tubercle; and there is no reason why, when we are doing all this, we should allow the most accessible part of the body to remain a favorable seat, not only for the propagation, but for the actual production of them. Therefore I consider that in regard to oral sepsis there is a wide field open for preventive medicine by the practice of oral antisepsis. When I say oral antisepsis, I do not mean any general application of mild astringents or antiseptic washes. I mean (1) the direct treatment of each lesion in connection with a diseased tooth by strong antiseptic solutions: carbolic acid (1 in 20 or 1 in 40) to be applied by means of a camel's-hair brush or a piece of cotton-wool directly over the diseased root. This application should be applied to each diseased tooth as long as the patient delays having the tooth removed. A teaspoonful of 1 in 20 carbolic acid in half a tumbler of water forms an agreeable mouth wash. (2) Still better, it can be done by removing all diseased stumps and roots, in particular those lying underneath any tooth plate. (3) There is a necessity for recognition on the part of the dental surgeon that the conditions he deals with are in all cases septic; he must not be simply content to give his patient a tooth plate and say 'Wear that.' The patient will have to be educated, and shown that these plates are the cause of septic trouble unless they are actually boiled. (4) There must be an entire avoidance of any dental apparatus which cannot be removed, and therefore which cannot be kept aseptic. This is a field of preventive medicine which I think you will find can be worked in with the most extraordinary success by the doctor, the surgeon, the dental surgeon, and the patient.

"There is another matter of very great practical importance. Who is to do all this? The physician sees the mouth condition, and sends the patient to the dentist. The chances are at least ten to one that the patient will not go there, because the dentist is associated primarily in his mind with the extraction of teeth. The surgeon looks upon sepsis in the mouth as coming within the domain of the physician, unless there be an actual disease of the jaw. The dental surgeon will treat the diseased tooth dentally, but he will not have his patients come back in order to be treated locally. So the poor patient is in the position of being driven about from one to another. I have been impressed by the neglect of the patient in this way, and I have tried, as I have narrated, the effect of sending patients in an extreme condition like case 3, that I have described, to the dentist. He came back without having anything done. Therefore the question is for each one to recognize that it is not an affair of the other. If you see a follicular tonsillitis or a quinsy you do not immediately pass the patient on to a throat specialist; you treat it yourself. This condition of oral sepsis is one which can be treated successfully by all, even by the patient himself, provided its septic nature and its importance as a disease factor be fully grasped.

"The effects I have described are very common. That

they are not even more common is solely due to the remarkably resistive powers possessed by the mucosa of the mouth. How rapidly wounds in the mouth heal is well known. Now, an important point in the cases of which I am speaking is, that pus derived from soft tissue is not so virulent as that which is derived from bone (tooth). It is only now and again, when the bone condition is very bad and the resistive power of the mucous membrane of the mouth is very much lowered, that you get the bad conditions which I told you of in the early part of the lecture.

"The great resisting power of the mouth is, however, no reason why such conditions of oral sepsis should be overlooked. How would you regard a physician or surgeon who allowed a patient to go about for many months, not to say years, with several small follicular abscesses in his tonsils? You would think it very neglectful; and if that patient came to you with a sallow look, and you saw pus on the tonsils, you would say at once, 'Here is the cause of the condition'; and rightly so. But it is the rule to neglect similar cases in connection with the teeth. It will show you how much it is overlooked when I tell you that notwithstanding all the literature pointing out the troubles due to septic organisms in the tonsils, oral sepsis does not seem to have received notice as a cause. Even in connection with stomatitis, mention is made of the irritation caused by a pointed tooth, or the stem of a pipe used by the patient, but nowhere is the reader told to look out for septic inflammation around the tooth. In connection with gastritis, mention will be found of the want of teeth, and the consequent imperfect mastication, as causes of indigestion; but nowhere, not even in the latest treatises on diseases of the stomach, will mention be found of necrosed teeth as a source of infection. Most strange of all, even when the condition of the stomach is one of suppurating gastritis, the rôle of every conceivable factor (errors in food and drink, etc.) receives full consideration; but not once is mention made of oral sepsis, even as a possible factor, although in one of the most striking cases related, the condition described as preceding the gastritis was that of septic ulceration all around the mouth, with necrosis of the jaw, and splinters of bone lying about."

Self-castration.—Dr. Daniel Stroch reports in the *Journal of the American Medical Association* for January 26th the case of a young white man, who was brought to the hospital about midnight on September 26, 1900. A couple of hours previously he had castrated himself, removing the entire scrotum. His appearance indicated that he had lost considerable blood, and the severed vessels were still bleeding. The scrotum was found to have been amputated close to the urethra, and the spermatic cords were retracted into the external abdominal rings. The vessels of the cords were ligated and the cutaneous flaps of the wound were sutured in the median line. A week subsequently the wound had healed by first intention; and it was expected that when cicatrization and contraction were complete there would remain only a median raphé, in close contact with the penis.

The man, in describing his operation, said he first tied a cord around the scrotum, above where he intended to cut, believing this was necessary to save him from a dangerous loss of blood. He then seized the scrotum and testicles in his left hand, and with a razor cut from above downward, with a sawing motion, severing successively all the structures. He said the "tendons" were more difficult to cut than the skin; that there was not much bleeding at first, but it became more severe in a few min-

utes. When asked if he was not tempted to abandon the procedure when he felt the pain of the cut, he replied that the pain was not very great, and he thought the flow of blood tended to prevent much suffering. He observed that the cord placed around the scrotum to prevent bleeding did not remain in position after the parts were severed, and to this fact he attributed the greater flow of blood that subsequently ensued. To the remark that he might have amputated the penis in his haste, he laughingly replied that he was careful not to do that.

A native of Switzerland, twenty-seven years of age, he had resided in this country fourteen years; a florist by occupation. His father, six brothers and three sisters were living, his mother dead, the cause of her death unknown. From his description, the members of his father's family were probably of a melancholy temperament and easily excited. Concerning himself, he said that he was always despondent, that his employers did not use him rightly; that he was nervous, and his memory poor. He always had some pain in his testicles, and frequently pain in the back. He had never practised masturbation; had never had sexual intercourse, and had never experienced strong desire for it. Involuntary emissions occurred at intervals of a month or six weeks, with the result that the pain in the back and testicles became less severe for a short period. Socially, he was always a recluse, and never associated with the opposite sex.

When questioned as to the immediate motive that prompted him to mutilate himself, he replied that it was because of the pain he experienced, and he thought by this means to obtain relief. He felt that his lack of success in life and his inability to please were due to the condition of his sexual organs, and he hoped by removing the offending members to obtain relief from the various influences that made him unhappy and a constant sufferer. He further said that he had for years meditated on the desirability of removing the testicles in certain individuals, to prevent the transmission of undesirable traits to posterity. He had no knowledge of the Skopzi, and was not familiar with the practices of that sect.

On the seventh day following the removal of the testicles an involuntary seminal emission occurred, during sleep, but was unattended with a lascivious dream: it caused him to awake immediately. The stain on the linen was examined ten hours later, and presented all the characteristics of dried semen. Washed with dilute acetic acid, a slide was moistened with the resulting mixture, and the microscope revealed the presence of spermatozooids, but not in large quantities, there being, on an average, from three to five in the field of observation. Following the emission, there was considerable pain in the wound.

The testicles, wrapped in a handkerchief, were taken with the patient to the hospital. They were of normal size and consistency, and minute inspection revealed that they were free from disease.

Cerebrospinal Meningitis.—Major Harold Brown, I. M. S. (*Indian Medical Gazette*, January), in a Report on an Epidemic of Cerebrospinal Meningitis in Calcutta, says:

"To sum up the treatment, it may be said that *fulminant* cases will die, whatever treatment be adopted, while the 'atypical' ones will recover with mere rest in bed. In the acute and subacute ones, general measures must be adopted, and symptoms should be treated on common sense principles, but it must be remembered that the sooner a case is removed from the place of infection, the better will be the chance of recovery."

Original Communications.

THE AXIS-TRACTION FORCEPS,
WITH SPECIAL REFERENCE TO ROTARY AXIS
TRACTION IN THE TREATMENT OF
POSTERIOR POSITIONS OF THE
ANATOMICAL HEAD.

By SIMON MARX, M. D.,
NEW YORK.

AFTER a very extensive experience with the Tarnier axis-traction forceps, I am in a position to call attention to the great scientific value of this instrument. This applies particularly to cases where a posterior position of the head, whether of the vertex or the face, presents; for I feel that the difficulties to be encountered in both these vicious positions are similar in a great many ways. But the occipitoposterior position is far more frequent than the mentoposterior, and yet the proper line of action is, in the eyes of many men, as much a moot point for the former as for the latter, even though the former, according to my experience, is of very common occurrence, either primary or persistent, while the latter is one of the rare complications encountered in midwifery. It is about two years since my first article appeared on this subject. At that time the attempt was made to impress upon my readers the absolute and great value of true axis traction. And yet there is still to-day as little interest shown in the use of the axis-traction forceps as formerly. Few know of its use, its application and worth; fewer still have ever applied it; and yet I doubt whether, when once its mechanism is understood, and once it is successfully employed, any other forceps would ever be tried again. It is remarkable that so valuable and truly scientific an instrument as the axis-traction forceps has found so little favor with the profession at large, and still more remarkable that so few of our obstetric teachers employ it. There is hardly a text-book but mentions axis traction, but they go no further. Most of them teach no mechanism of application and mode of delivery, simply stating that axis-traction instruments exist, and allowing the subject to pass in as few words as possible. In my first article I made use of the following lines, which I beg leave to quote: "To my mind, there are no instruments that we are called upon to use which are more, if I might say, intelligent than these. They are strength-saving to the accoucheur, safe for the mother, and eminently more safe for the child. Whilst they have much, very much, in their favor, yet there are certain objections to their use which, in a great measure, cannot be overcome, and these objections do not all hold good, since they apply with equal force to the ordinary obstetric forceps."

With many the greater expense of the instrument would deter them from procuring it. And the necessity of having more than one forceps would, again, be an ob-

jection. Since beginning its employment, now more than eight years ago, I have never found the need of using any other than the Tarnier forceps in a very large private, consulting, and hospital practice. In fact, it is the only obstetric forceps I have used in this time. The greater expense is certainly fully compensated for by the amount of muscular energy saved and the diminished risk to mother and child.

A possible objection to the forceps is its length, making proper sterilization a difficult task. This can be readily overcome by using a baby's bath-tub for this purpose.

FIG. 1.

There is no greater difficulty in the application of the blades themselves. But the necessity of the attachment of the traction rods would make the entire procedure seemingly a perplexing one: but does this not apply to the general statement that the more scientific an instrument and the more complex its mechanism, the greater the difficulty of its application? This is readily overcome and soon mastered by increasing experience.

Unless one is skilled in its use, or the lines for its application are not closely followed, the danger of slipping is vastly increased, being far greater than with the ordinary forceps. I have seen, in the hands of an otherwise very skilful accoucheur, who for the first time applied a

Tarnier, a complete rectovaginal laceration occur from an improper mechanism and consequent slipping of the instrument. When this accident occurs, the danger to the maternal and foetal structures is far more profound than ordinarily. And yet in all hands, expert or inex-

FIG. 2.

pert, slipping of the instrument occurs once in a while. No matter what forceps is used, an unsafe or uncertain seizure should at once suggest that a persistent use of no matter what forceps is fraught with considerable danger, not alone as to lesions, but also as to probable failure in extraction; hence one or the other of the alternate operations is called for. If the instructions given below are closely followed, the danger from this direction will be reduced to a minimum.

The last danger is one, not of life, but of disfigurement; but this can be overcome by entirely discarding the fixation screw. This screw, it was formerly believed, kept the forceps blades in place, and, giving them a firmer purchase, prevented the possibility of slipping. This has been proved incorrect in practice, for it is now a well-known fact that the blades are kept in place by the impact of the foetal head and the pelvic wall. With the fixation screw in action, it has been my painful experience to note, on many occasions, pressure necrosis at the points of application of the blades on the foetal

skull. In one case a permanent and ugly scar was the result. Accordingly, from my experience, the screw is an obsolete fixture and is of no value whatsoever. Since it is of no use and can only harbor dirt, as well as materially confuse the accoucheur and increase the difficulty of application, it should not be present in the newer models. As to the advantages of the modern axis-traction forceps, such as Tarnier's or the Jewett, they are overwhelming. This I pointed out in a paper which I read and published in March, 1894.* My very much increased experience since that time has not caused me to modify the views I then held. I must therefore be pardoned if I quote literally from this work. These remarks are limited to those instruments minus the perineal curve (new model). With the ordinary forceps in action we must, of necessity, influence moulding, rotation, and descent of the head, through our purchase upon the handles, by traction and pressure on the head. This is not so when the Tarnier instrument is used. Here the handles of the forceps are left alone. They

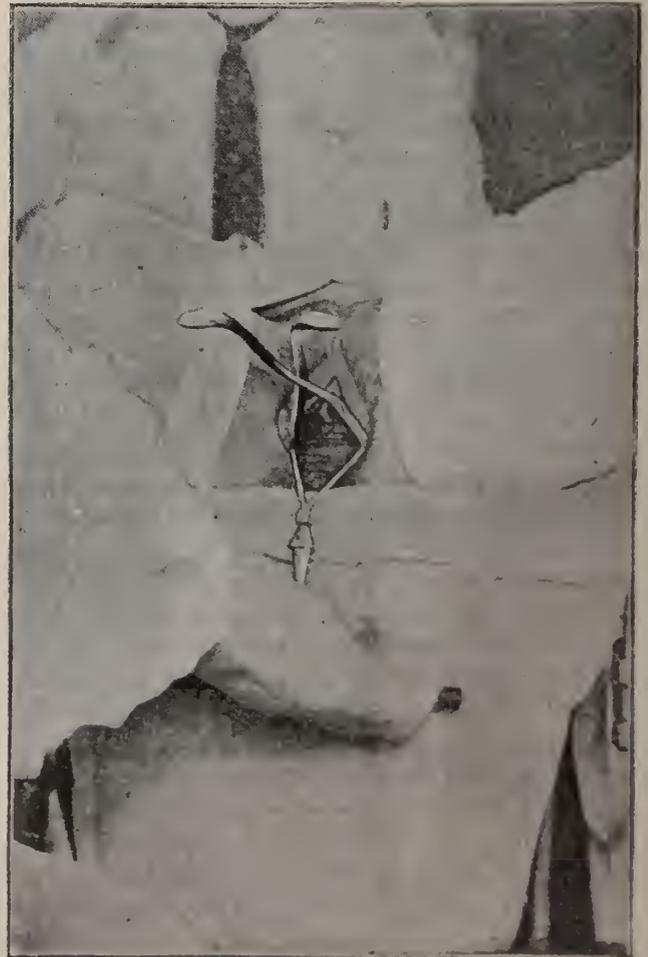

FIG. 3.

are simply used to act as an index as to the position of the head and as a guide to the direction in which we are supposed to make traction. Our extraction force is directly applied to the cross-bar of the traction rods,

* *Medical Record*. Study of Occipitoposterior Positions.

which is used to drag the head uninfluenced through the pelvic canal. Rotation can then occur in due time, as it does in the great majority of cases (occipitoposterior cases). Therefore, the great advantage in using axis traction is the free mobility of the forceps when applied to the head. With the ordinary forceps, the mechanism, as compared with the shape of the pelvis, seldom comes into operation; in fact, the mechanism is often interfered with unconsciously, so as to materially disturb the descent and evolution of the head, possibly checking or influencing what would otherwise be a normal position of the foetal head; while, with the Tarnier forceps, the head, with the body of the instrument, obtains greater freedom of mobility.

A further great advantage applies to the child, and is of the utmost importance, immediate and remote, as to life and health. The ordinary compression force, as applied to the foetal skull by the forceps, is variously estimated at about twenty-five pounds. Further, twice this compression force, or fifty pounds, represents the traction power. In a very difficult delivery, where enormous strength is exercised to deliver, this force is materially increased to a power one shudders to estimate in pound weight. Every pound of increased traction means half a pound of compression force. In other words, with the ordinary forceps, the more powerful the extraction force applied, the greater the compression exercised upon the foetal skull, no matter how carefully done; and no matter what amount of resistance is placed between the handles at any point, to lessen the compression power, too much space between the handles absolutely insures a loose or unsteady application of the blades, and consequently far greater disposition to slipping. This is entirely and absolutely overcome in the axis-traction instruments, where practically no pressure is brought to bear upon the head, since all the extraction force is applied directly to and from the cross-rods.

The last, and to my mind the greatest, advantage possessed by the instrument is its saving of muscle and strength on the part of the operator. A case that has proved to be futile of success with the ordinary forceps will yield with the axis-traction instrument in a remarkable and rapid fashion. With a minimum amount of force expended and none lost, it often seems marvellous with what ease delivery is effected in an apparently difficult case. Further, the severest trial the average physician has, is to determine in what axis he has to exercise traction in order to deliver the woman successfully. The tendency is generally to pull too far forward and upward. With the ordinary instrument there is absolutely no trustworthy guide as to traction in the proper axis. Consequently, there is not only greater danger to mother and child, but failure will almost invariably follow as to successful delivery. This is entirely overcome with the axis-traction forceps. Here, the handles of the forceps are an extremely useful guide as to the position of the head, and, consequently, an ever-

guiding factor, a compass, as it were, as to the direction in which the force of the extraction is to be applied. As to the indications for its use, they do not differ in any way from those of the ordinary forceps, generally speaking, as with it the head must be engaged, or, if it is not engaged, there must be a contra-indication to the performance of a version or other conservative operation; again, the position and presentation should be normal, or relatively so, or, if abnormal, readily correctible by hand or instrument, and the maternal parts in a condition to allow of the passage of the child without endangering their integrity.

FIG. 4.

In the application of the forceps, the same rule applies as in the use of the ordinary instrument, except that, when it is in position, the traction rods are attached. With the exception of those cases in which it becomes necessary to institute what I call "rotary axis traction," the forceps is applied, as an invariable rule, to the sides of the pelvis. Great stress must be laid on the following lines, for, if the directions are not properly followed, the most severe lesions may be provoked. It should be remembered that, when the ordinary forceps is used, especially if the head is at all high, the handles look much farther backward than when the axis-traction forceps is used. If one is not accustomed

to the latter, one will instinctively take hold of the cross-bar, and, taking no note of the forceps handles as a sure and positive index as to the position of the head in its relation to the pelvis, will pull directly backward and away from them, thus doing what one has been accustomed to do in what would be the proper line of procedure in using the ordinary forceps. Instantly, because of improper leverage and action, the handles will fly upward and away from the traction rods, and the operator will find the empty forceps in his hands and outside of the vagina, with probably a completely split rectovaginal septum. The following rule must always

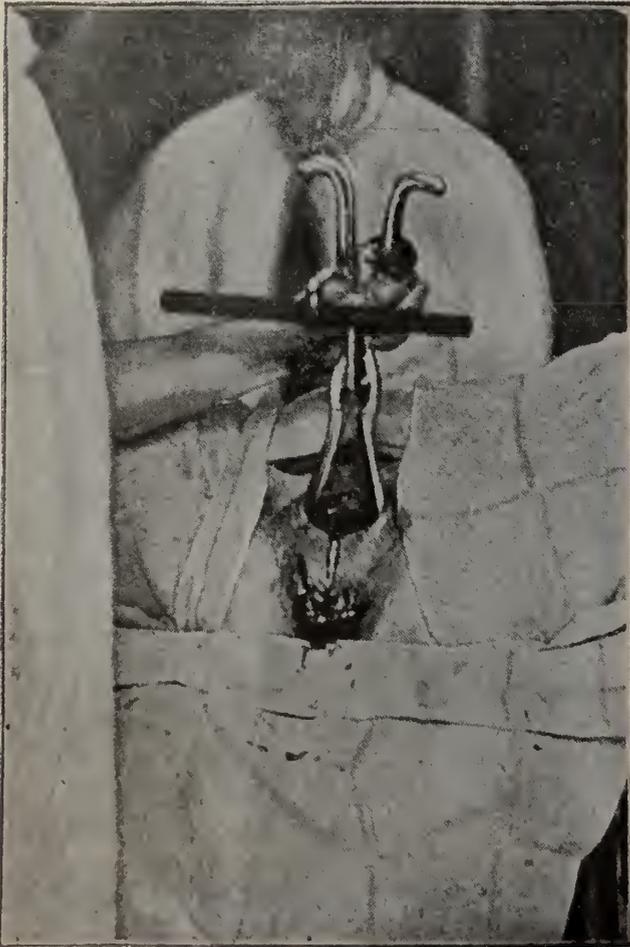

FIG. 5.

be borne in mind, and, if it is adhered to, no such accident can ever possibly happen: The handles of the forceps must always be our guide as to the direction of traction, no matter what their position. This is the secret of success and puts the whole thing in a nutshell. No matter how high the head is situated in its relation to the pelvis, it must never be taken into consideration, and certainly it must never influence us as to the direction of our traction energy. A maxim worth remembering is to follow closely the handles of the forceps, no matter where they point. The button on the traction handle or the point of junction of traction rods must always be nearly in contact with the traction handle, just barely

touching, and this relation must be maintained until the child is practically extracted. To allow the two parts, *i. e.*, forceps handles and traction button, to come in contact will at once influence the utility of the handle-tips as indices, for by this contact the tendency would then be to push the handles too rapidly forward, and so to give us a false conception of true and ideal axis traction. Thus its effect would be spoiled and our energy rendered futile. Grasping the traction cross-bar with both hands, one on each side of the central bar, traction is then made and continued, the traction handles being carried farther forward and upward, always following closely the direction of the handle-tips, until the head begins to crown. At this stage either the forceps is removed, or, if delivery is to be completed with the instrument *in situ*, the operator, standing to one side of the patient, grasps both traction rods and forceps handles in one hand while with the other he manages the perineum.

Having now finished with the simpler technique of ordinary axis traction, I beg leave to call attention to a method that I have been using for a number of years with almost uniform success. I have given it the name of *rotary axis traction*, because by this manoeuvre we fulfil a compound indication, *viz.*, axis traction and, at the same time, artificial rotation. These measures are particularly applicable in cases of posterior position of the head—occipitoposterior or mentoposterior positions. It is admitted by all accoucheurs that in the largest number of these malpositions spontaneous rotation occurs. It must further be remembered that this rotation, in the largest number of cases, occurs at the pelvic floor. Yet, in spite of all known legitimate measures to correct these vicious positions, it occasionally happens that the proper rotation does not occur. The measures to be instituted would include manual rectification and restitution, forcible flexion or extension of the head, postural treatment (in my hands the most efficacious), and forced instrumental rotation (risky and dangerous). Here, then, we are in the presence of a very disagreeable, if not positively dangerous, complication. The indications are given as above. We interfere only when we note a disposition to complete posterior rotation. When, instead of the small fontanelle swinging around toward the front, as in normal cases, it rotates into the hollow of the sacrum, we interfere at once, since, when once impaction occurs, nothing short of direct traction with the forceps or other alternative operations is indicated. This carries with it so much danger to the maternal structures as well as to the child that it has become, to me at least, a kind of nightmare. The most extensive lesions I have ever seen have occurred in just these neglected, or at best unrecognized, cases of occipitoposterior position. This is just what I wish to avoid, and it has been my good fortune to see this complication—that is, cases of impacted occiput or chin-posterior cases—but very seldom. In many, by the

use of the axis-traction instrument, I have often succeeded in rotating the head anteriorly by simply allowing the head, while traction is being made, to be influenced by the factors supplied by Nature (the resistance offered by the perineal structures and furthered by the turning points afforded by the ischial spines, especially when they are prominent) to provoke such rotation. And herein lies the utility of the instrument, as stated above. It allows the head to pass uninfluenced through the pelvic canal, except for the natural influence which promotes rotation; hence the great advantage in the free mobility of the forceps when applied to the head. This rotation begins to occur when the head descends to the pelvic floor, and is instantly evinced by the

oblique diameters of the pelvis, insure a more certain purchase, and very materially aid in the success of this otherwise rather simple manœuvre. With the right hand, steady traction is made (or an assistant can manipulate the traction bar), and at the same time, with the left hand, the handles of the forceps are compelled, or at least influenced, by gentle rotation to turn in the direction of the presenting part; to the left in left posterior cases, to the right in right posterior ones. This applies equally in face cases, taking the chin as the analogue of the occiput. This manipulation must be persisted in, slowly rotating all the time while making careful and intermittent traction, timing our measure so that when the head reaches the pelvic outlet complete

FIG. 6.

behavior of the blades. They begin to rotate with the head, the movement increasing with every traction effort, until the forceps has entirely rotated. They place themselves inversely, as Pajot would have us apply them in persistent posterior cases. They are then removed and applied as in ordinary cases. Where, however, for some reason or other, no such tendency to rotation occurs, the normal mechanism is probably at fault, and at this time the rotary axis traction becomes of supreme value. We assist Nature and stimulate rotation by rotary axis traction. The forceps is applied *lege artis*. It may be applied according to the pelvic walls; but an oblique application, *i. e.*, to the sides of the child's head, is far better. When in such a position, they conform to one of the

rotation shall have occurred and the forceps blades shall be found nearly or entirely inverted. At no time should brute force be used, but the greatest gentleness should be exercised at all times. I have on a number of occasions tried forcible rotation by the ordinary forceps, and have succeeded, but at the expense of the maternal structures, with resulting deep lesions of the vagina and pelvic floor. I have tried "rotary axis traction" scores of times, and have *seldom* failed when the forceps was applied to the sides of the pelvis, and *never* when it was applied to the sides of the foetal skull. The resultant lesions were no deeper or more frequent than in ordinary simple forceps extraction.

947 MADISON AVENUE.

METRORRHAGIA DUE TO INFLAMMATORY PROCESSES WITHIN THE PELVIS.*

By EDWIN B. CRAGIN, M. D.,
NEW YORK.

IN the discussion of the ætiology of metrorrhagia due to inflammatory processes within the pelvis, three factors must be considered:

1. The endometrium.
2. The muscular wall of the uterus.
3. The blood-vessels of the uterus.

A. The Endometrium.—The general rule holds that, given a metrorrhagia, expect to find an endometritis as its immediate cause. Exceptions will be spoken of later.

While it is generally recognized that endometritis may be either *acute* or *chronic*, and its origin either *bacterial* or *non-bacterial*, frequent bacteriological examinations of the uterine cavity, the seat of a chronic endometritis, have proved it sterile and the endometritis non-bacterial in origin, in a very large number, if not in the majority, of cases. It is acute endometritis, then, whose ætiology we assign to pathogenic bacteria, introduced at various times and in various ways; at full-term parturition, or the puerperium; at abortion or operation, by dirty fingers, dirty instruments, retained secundines, etc.

While it is admitted that during an acute endometritis there may be at different times a mucopurulent discharge streaked with blood, an acute endometritis is of such short duration and the metrorrhagia, if present, is so slight in amount, that we may practically dismiss acute endometritis as a common cause of metrorrhagia.

With chronic endometritis, however, metrorrhagia is commonly associated.

Given a uterus with a normal muscle wall and normal uterine vessels, a smooth endometrium usually means normal menstruation and no metrorrhagia. A rough, hypertrophied endometrium means menorrhagia or metrorrhagia, or both.

For the usual ætiology, then, of metrorrhagia we must look to a chronic endometritis and its causes. Although chronic endometritis may be the result of an acute endometritis of bacterial origin, certainly in a large number of cases it arises as a result of a chronic congestion, in the same way that chronic inflammation follows chronic congestion in any other mucous membrane.

Situated as the uterus is, between two viscera, one of which at least, the rectum, is often in the condition of distention, and prone as the uterus is to displacement from relaxation of its supports and increased weight, chronic congestion of the uterus in general, and of the endometrium in particular, is easy to understand, as a result of obstructed venous return.

When we consider the situation of the uterus, in

juxtaposition to the Fallopian tubes, ovaries, peritonæum, and cellular tissue, often the seat of inflammation, chronic congestion of the endometrium, as a result of increased flow of blood to the part, is also easily understood.

Chronic congestion of the uterus, the result of disease of distant organs, is to be discussed by other speakers.

In the opinion of the writer, then, the usual order of source and sequence is: chronic congestion of the endometrium; chronic inflammation of the endometrium; menorrhagia and metrorrhagia.

B. The Muscular Wall of the Uterus.—No one who observes carefully, during parturition, the action of the uterus in controlling hæmorrhage can fail to realize that on the contraction of the irregularly arranged fibres of the muscular wall depends the amount of blood flowing through and from the uterus. If this contraction is normal and unimpeded, the circulation of the uterus and the loss of blood from the uterus is normal. If the contraction of the muscular wall is in any way interfered with, the amount of blood flowing through and from the uterus is abnormally increased.

This same relation of muscular contraction and blood-flow holds, in the opinion of the writer, in the non-pregnant uterus, and anything interfering with the normal contraction of the uterine muscle, other things being equal, favors an excess of blood through the uterus, menorrhagia and metrorrhagia.

The two conditions most commonly interfering with normal contractions of the uterine muscle in the non-pregnant state are:

1. Tumors of the uterine wall, the discussion of which does not belong in the division of the subject assigned to the writer.
2. Chronic interstitial inflammation of the uterine wall, in which there is atrophy of the muscular tissue and an increase of new connective tissue.

Although both of these conditions most often produce metrorrhagia through the medium of a chronic endometritis, occasionally one meets with cases in which the endometrium seems but slightly involved, and the bleeding seems to be caused by a lack of sufficient elasticity in the uterine muscle, due to interference with the normal muscular contraction.

C. The Blood-vessels of the Uterus.—In the same way that interference with the normal muscular contraction of the uterine wall favors an excess of blood in and from the uterus, so interference with the normal contraction of the arteries themselves favors the same result. Occasionally, especially in the latter part of menstrual life, and often associated with the two conditions just discussed, viz., tumors of the uterine wall and chronic interstitial inflammation of it, one finds the vessels of the uterus in a condition of arteriosclerosis, with insufficient elasticity either to maintain the normal

*Read at a meeting of the Medical Association of the Greater City of New York, February 11, 1901.

balance of uterine circulation or to check the flow beginning at a menstrual period. Here, again, although this inflammation of the arterial wall usually produces metrorrhagia through the medium of a chronic endometritis, occasionally cases are met with in which the endometritis is slight, or does not respond to the use of the curette, and the hæmorrhage seems due to the lack of contractile power in the arterial wall.

The question of the treatment of metrorrhagia depends very largely on its ætiology. As the most usual immediate cause is a chronic hypertrophic endometritis, curettage, followed by endeavors to relieve the chronic congestion, is usually the best treatment.

When due to an acute endometritis, cleanliness, drainage, and rest usually give the best results.

The treatment of metrorrhagia due to interference with the muscular contraction of either the uterine wall or the uterine vessels, depends upon the presence or absence of an hypertrophied endometrium. The presence of the latter indicates curettage, perhaps several times repeated.

Metrorrhagia, with an absence of hypertrophied endometrium, or persistent after repeated curettage, may justify hysterectomy.

62 WEST FIFTIETH STREET.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

By NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

NEW YORK,

ATTENDING SURGEON, POST-GRADUATE HOSPITAL.

(Continued from page 324.)

CAUSES ATTRIBUTABLE TO THE MOTHER.—Having considered the general and specific conditions on the part of the father which may contribute to the death and expulsion of the fœtus, we will now proceed to investigate reasons which may be referable to the mother. We shall find them to be much more numerous and complicated. It is reasonable that this should be so. If the father supplies the ovum with spermatozooids of sufficient inherent vitality, his responsibility, so far as the future of the fœtus is concerned, comes to an end. Its subsequent career depends absolutely on the general constitutional and local conditions of the mother. These are extremely broad, comprehensive, and in many instances so inscrutable as to be exceedingly difficult to detect. There are almost innumerable agencies which may so affect the general health of the mother as to have a detrimental influence on the growth and development of the embryo. All agencies which conduce to deterioration of the mother's health converge in this direction. Thus, unhealthy surroundings, pernicious habits, unsuitable occupations, insalubrious climate, or extremes of heat and cold, have their influence in lowering the strength and vigor of the mother. The same may be said of artificial ways of dressing, tight lacing, irregular or late hours, lack of healthy

exercise in the open air, anxiety, worry, grief or mental depression of any kind. These all enfeeble and depress and have a baneful influence on the health of the mother, and consequently on the well-being of the fœtus. Many of these may not in themselves be sufficient to directly lead to intra-uterine death, but are yet of sufficient importance to so lower the resisting powers of the constitution that other and more remorseless diseases may supervene. Women who lead luxuriant and indolent lives, and those who endeavor to keep pace in the smart set of society, are more liable to miscarriage than those who are satisfied with a quiet, peaceful life, and who walk in the ways of physiological righteousness. The former are not the best candidates for maternity. Moving from a cold to a hot climate frequently has an indefinite, although an insidiously detrimental, influence upon the reproductive organs. Changes from sea level to mountainous regions cause a congestion of the pelvic organs and increased maternal circulation. Catamenial hæmorrhages are more profuse and the procreative machinery is prone to be thrown out of gear. These conditions are incompatible with normal pregnancy in many instances. Wild animals of the jungle, accustomed to roam listlessly about, bellowing out their freedom, are, when held in captivity, liable to abort. The seeds of trees or plants which grow in one climate will, when transplanted to another, bring forth monstrous leaves and seedless fruit, if they do not perish by the change. We have the parallels and analogues in women. Over-feeding and over-stimulation have a harmful effect upon child-bearing. It is difficult for an obese woman to become pregnant, and, if she does, there is great liability to a miscarriage. Stockmen have long recognized the influence of a superabundance of adipose tissue in their cows, mares, or sheep, and they tell you that it is almost impossible to breed from animals that are "too fat." Obesity has a pernicious influence in producing sterility as well as in imperiling the safety of the fœtus should pregnancy take place. The pathology of this is not thoroughly determined. We incline to the opinion that overloading of the tissues with more material than they can assimilate, becomes in a way a general disturber of many of the functions of the body and tends to pervert the physiological actions of the uterus. Indirectly, this influence is detrimental, but the particular manner by which the death of the embryo is brought about in these instances is, no doubt, due to passive congestion of the endometrium. An impediment to the regular normal flow of blood in both the uterine and ovarian veins could readily be caused by the extra amount of pressure from fat, and so cause such a condition. This is eminently theoretical, but presents logical reasons for this anomaly.

Anæmia.—That anæmia will produce the death of the fœtus is well recognized. Sudden losses of large quantities of blood from the maternal circulation have been known to produce convulsions of the unborn child and to cause its death. Gradual depletion may eventu-

ally lead to syncope of the pregnant woman, and may so disarrange the uteroplacental circulation and cause such a feeble amount of nourishment to the embryo as to starve it to death. It is quite possible for a very anæmic woman to become pregnant, but the condition is usually aggravated after conception, and the foetus generally starves.

Normally, there is relative chlorosis during pregnancy. The red blood corpuscles are materially diminished in number and the watery constituents of the blood become correspondingly increased. Long ago these changes were investigated and recognized. They can at any time be confirmed. For the first six months of pregnancy the fibrin of the blood diminishes perceptibly, but during the later months it increases again, and eventually becomes abnormal. Because of the extra amount of labor imposed upon the blood vessels, their tension is greater, they increase in size, and the pulse rate is accelerated. There is, as it were, a physiological anæmia or normal leucocytosis of pregnancy. Sometimes this condition becomes extreme and may endanger the health of the mother to such an extent as to imperil the life of the foetus.

Interbreeding in animals, as well as in plants, has a tendency to produce mental and physical deformities, defects, and even premature death in the former, and immature leaves and seeds in the latter. Conception occurring in either extreme of the productive period of child-bearing life is not conducive to a satisfactory progress of pregnancy. In eastern countries where girls mature early, and where the custom of early marriages is prevalent, miscarriages are exceedingly frequent. This is probably owing to the uterus not being yet sufficiently developed to meet the requirements of the drain it is so early called upon to fulfil. It is equally so in the other extreme of the child-bearing period. It frequently occurs that the last-born of a woman is defective in some particular. Abortions are common, but should gestation proceed to the full term, it is a prevalent opinion that the child may be an idiot or physically defective.

There have been known to be epidemics of abortion. During famines, sieges, or similar catastrophes, women abort quite frequently. In these instances, fear, famine, and emotional causes have probably acted in conjunction in bringing about the result. Women who have been sentenced to be hanged very often abort if pregnant.

Small-pox.—This affection has a serious influence on the safety both of the mother and child. It is said to be much more serious in the confluent than in the discrete variety. Abortion takes place oftener during the suppurating stage than during any other in the progress of the disease, although it may be brought about in any period. It may be regarded as a conservative and beneficent effort upon the part of Nature to get rid of the child in these cases. The poison is frequently too overpowering to save both mother and child, and when it centres

itself principally upon the foetus, it causes its death and expulsion, and in this manner diminishes the virulence of the attack, so far as the mother is concerned. It is difficult for Nature to reconcile any serious concurrent disease with pregnancy, especially if there is considerable increase of temperature. Just how abortions are brought about in such instances has not been fully determined. Probably the morbid poison circulating in the blood of the mother transfers poisonous gases to the foetus in the placenta, and in this way has the most potent influence in causing the death of the child. All diseases accompanied by an unusual degree of pyrexia have a dangerous effect upon the foetus, and it is altogether probable that the increase of temperature has a direct and powerful influence in such disasters. That the mother can convey the disease to the child is abundantly established by finding small-pox pustules covering its skin. Uterine hæmorrhage is stated to be a frequent accompaniment of small-pox, and many authors attribute the expulsion of the child to hæmorrhagic endometritis. Brouardel maintains that the death of the foetus in a woman suffering from small-pox is entirely due to the alterations of the maternal blood, consequent on the increase of carbonic acid, which asphyxiates the child, and this in turn brings about uterine contraction and its ultimate expulsion.

Typhoid Fever.—Many of the older writers maintain that typhoid fever renders pregnant women immune against typhoid fever, but more recent investigators have sufficiently disproved this theory. When a woman in such a condition, especially if pregnancy is far advanced, contracts this disease, it is almost universally fatal to both the mother and child. In typhus, on the other hand, the danger is not nearly so great to the mother, and the child generally goes to the full term and is born alive. Relapsing fever, from some unexplained reason, is unusually fatal to the foetus. Smith and Jackson give the history of thirty-six pregnant women who were attacked with relapsing fever, and all aborted except one. Should pregnancy be far advanced, almost universally the child is stillborn. Weber, of Berlin, investigated sixty-three cases of typhoid fever in pregnant women. Twenty-three of these patients aborted and forty went to the full time. Charpentier collected 322 cases of pregnant women having typhoid. Of this number, 182 aborted and 140 children were born alive. This gives a foetal mortality of fifty-six per cent. Both Charpentier and Spiegelberg claim that the death of the foetus is not so much due to the form that the fever may assume as it is to the period of pregnancy. The danger, according to these authors, is greater in the early stages than it is when the foetus reaches the later months of pregnancy.

Scarlatina.—This disease does not seem to be so inimical to pregnancy as might be expected. It is even inferred by many that scarlet fever is to a certain extent incompatible with pregnancy. This, however, is not so, for there have been known epidemics of scarlatina so virulent as to assume an alarming form and to cause

many women to miscarry. It is a particularly perilous complication during the puerperal state.

Erysipelas and *Measles* are not so dangerous to the life of the foetus as typhoid fever or scarlatina. They do, however, sometimes bring about the death of the embryo. During the progress of measles it is in the midst of the eruptive stages, and when the fever is at its height, that abortion is the most liable to occur.

Pneumonia.—Abortion is singularly prone to follow severe forms of pneumonia. The safety of the child depends considerably upon the date of pregnancy. When in the last months of gestation pneumonia attacks a woman, it is quite possible for a viable child to be born, provided the child is rapidly expelled. In the earlier stages, when miscarriage is brought about, the placenta is usually retained, which fact gravely aggravates the seriousness of the disease. There may be several conditions, acting singly or in conjunction, to account for the death of the foetus in pneumonia. There are general constitutional derangements with their various sympathetic reflex disturbances; the severity and violence of the cough; the rapid rise of temperature and the suddenness of the attack; disarrangement of the maternal circulation and accumulation of carbonic acid in the blood. Each and all of these are inimical to the well-being and safety of the embryo. Rican, in investigating this subject, collected forty-three cases of pneumonia having pregnancy as a complication, and found that the foetus was killed and prematurely expelled in twenty-six.

The manner in which these various acute diseases, somewhat hurriedly enumerated, cause the death and expulsion of the foetus are no doubt numerous, and in many instances complicated. A study of these symptoms is singularly interesting and instructive. There are certain of them of much greater importance than others. In taking a general survey of the subject, it will be found that they are all associated with elevation of temperature, and we affirm that, when pregnancy accompanies any of these diseases, the safety of the foetus depends largely upon the degree of temperature that is attained. There are no doubt subsidiary influences contributing toward this end, but the fundamental disturber of life, so far as the embryo is concerned, is the unusual degree of body heat. According to Hohl's investigations, he found that the temperature of the mother invariably had an influence on the child and affected in a peculiar manner the temperature of the foetus. When the mother's temperature increased, that of the child was correspondingly elevated. When it diminished, again, the pulse rate of the child was similarly affected. Huter carried out a series of observations on the same line with a like result. Friedler had an opportunity of watching two cases of typhus fever in pregnant women. The pulse of the foetus in each case showed the foetal circulation to be increased in parallel ratio with that of the mother, even to the morning remissions and evening elevations. During an epidemic of typhus in Rus-

sia, Kaminsky saw no less than eighty-seven cases accompanied with pregnancy. Of this number, fifty-five were during the first half of pregnancy, and thirty-two were in the last half. So long as the temperature was but slightly elevated, no perceptible effect on the foetus was noticed, except a corresponding rate of the heart beat. When, however, the thermometer indicated a temperature in the mother of 104° F. or over, there was a distinct disturbance to the foetus besides the increased heart beat. Increased movements in the uterus were noticed; sometimes these were quite tumultuous. They continued well marked until the temperature reached the neighborhood of 108° F., when they ceased entirely and the child died, as was discovered afterward. It was not however, always immediately expelled from the uterus, but was retained for a certain time. When the pregnancy was in the latter months, there were only two cases where uterine hæmorrhage was present. When pregnancy was not far advanced, hæmorrhage was fairly frequent. The danger line was reached at a temperature of 104° F., and increased with its advance. The greater the degree of maternal heat above 104° F., the more surely came the death of the foetus. When Runge was made familiar with these observations of Kaminsky, he determined to make investigations on lower animals as to the effects of high temperatures on the gestation of animals that were pregnant. For this purpose he experimented upon rabbits. A number of these pregnant animals were placed in a box specially constructed so as to admit of good ventilation and of its maintenance in keeping with usual atmospheric conditions. In ten minutes he increased the temperature in the box to 122° F. The temperature of the rabbits increased one degree every minute for forty-five minutes, or until a temperature of 109° F. was reached, when they died, if they were not removed from the heat. The interesting and practical point is that the foetuses invariably died when a temperature was reached which was not yet sufficiently high to kill the mother. In another series of experiments, the same author took the maternal temperature every ten minutes until it recorded 39° C. to 42° C., when he killed the animals. When the uterus was opened, it was discovered that the temperature of the foetus was always a little higher than the maternal temperature. Every time the temperature reached 106° F., the foetus was found to be dead, and it was always alive when the temperature did not reach beyond 104° F. In the margin between 104° F. and 106° F., the foetus was sometimes found dead, but as many times it was alive. On examination as to the lesion found after death, the right ventricle was found distended with blood and widely dilated. The left ventricle was contracted and quite firm. From these experiments the author draws the following deductions:

1. A foetus has always a higher temperature than that of the mother.
2. In zymotic diseases of the mother, the foetus dies

when the temperature goes above 104° F., and before the same temperature becomes fatal to the mother.

3. The danger to the foetus does not cease after the temperature has risen above 104° F., although the mother's temperature may in a short time become normal. In order to ascertain the accuracy of these inferences and to know for a certainty whether the animal heat of a foetus is proportionately higher than that of its mother, when normal conditions prevail, as well as when the temperature is elevated from some disease, a number of investigations were undertaken on our own behalf. As the temperature of a rabbit is normally from a degree and a half to two degrees higher than human heat, it was thought best to select an animal whose temperature corresponded to that of man. For this reason cats were used. The best clinical thermometers were selected, after being thoroughly tested as to their accuracy. It will be remembered that chloroform has a tendency to lower the ordinary temperature of these animals, if given suddenly and in large quantities. Before putting the cats under the anæsthetic and submitting them to the experiments, their temperatures were all taken, to see what difference, if any, there was between them. This was done by placing a thermometer in the rectum for the period of five minutes in each case. They ran uniformly at 99.4° F. in each case. After the anæsthetic was given, the temperature was again taken, and it was found that it had fallen between 0.1° F. to 0.2° F. The abdomen was then opened and the uterus exposed. An incision was made into it sufficiently large as to bring a foetus into view. A thermometer was placed in the cavity of the womb, another in the body of a foetus, and still another in the vagina. They were held in their respective places for five minutes and then removed. They showed the following registration:

Vaginal.	98.4° F.
Uterine.	98.8° F.
Fœtal.	99.3° F.

The remaining cats were similarly operated on and gave practically the same results. Hysterectomy was performed on all of them, and four of the number recovered. On three occasions we have had an opportunity of ascertaining the temperature of a foetus *in utero* in breech presentations. When the os was sufficiently dilated, and in the interval of the pains, a thermometer was inserted into the foetal anus for a period of five minutes. The vaginal temperature of the mother was taken at the same time. In each instance the temperature of the foetus ranged a little higher than that of the mother. The average was six tenths of a degree. When taken collectively, these various experiments on different animals are singularly instructive. They demonstrate that the foetal heat is higher than that of the mother, and that when the temperature of the latter is increased by disease the foetal temperature rises synchronously with it. During gestation, it is quite prob-

able that, from the increased activity of function of the uterus, there is a greater amount of bodily heat in this organ than in other parts of the body. It is quite well known to physiologists that when increased metabolism is going on in the liver, the heat of this organ is greater than the normal temperature of the body would indicate. Especially is this the case shortly after meals.

We have dwelt at considerable length on increased bodily heat as a factor in bringing about the death of the foetus because of its importance.

Just how a temperature of 104° F. or over kills the foetus is a disputed point, and conflicting views have been maintained upon the subject. There is no doubt that the *cardio-accelerator* centre becomes much affected for in these cases the heart beat is greatly increased, indicating that its control centre has become much disturbed. For a time it is much agitated, and afterwards paralyzed. It is extremely probable that the solution may be found in the amount of imperfectly aerated blood which is charged with a greatly increased quantity of carbonic acid during these diseases. We know that this acid has a remarkable way of stimulating the medulla and other nerve centres. When the proper balance between the amount of oxygen inhaled and of carbonic acid displaced is properly maintained and correlated, no detrimental effect is produced, either to the mother or the foetus; but when the maternal circulation accumulates in the uterine sinuses, laden with carbonic acid, uterine contraction is induced, and in the meantime the foetus may perish from asphyxiation. When a foetus is expelled from a mother who is suffering from a disease associated with high temperature, it almost always has a cyanosed or livid appearance. This is caused by the capillary vessels becoming overcharged with carbonic acid as a result of a deficiency of oxygen. If a post mortem examination is made, it will be found that the blood vessels in the interior of the body will be highly engorged and congested, as well as those on the cutaneous surface.

Eclampsia.—This disease is particularly fatal to the foetus, and frequently to the mother as well. Whether or not it arises from the accumulation of urea, albumin or some other deleterious substance circulating in the blood of pregnant women, its poisonous influence during the later months of pregnancy is one of the most formidable conditions with which the obstetrician has to contend.

Its exact ætiology still remains in doubt, and its precise pathology is yet being considered. When Leveillé demonstrated to the profession, in the year 1843, that women suffering from the convulsions of eclampsia usually had their urine heavily loaded with albumin, it was thought that the pathology of the disease was at last understood. This opinion was not, however, long entertained, for it was found that many pregnant women who had an abundance of albumin in the urine showed no evidence of convulsions. Later, Ferriehs maintained

that they were not due to albumin or urea, but to carbonate of ammonium, a decomposition product of urea. It is very probable that the toxæmia resulting from the retention of urea circulating in the blood will not clearly account for the onset of such convulsions. Puerperal eclampsia and the convulsions of uræmia are markedly dissimilar in one important particular. In eclampsia, the temperature invariably rises from the beginning of the attacks to the end. During the interval the high temperature is maintained, and rises still higher with the succeeding attacks, and may even reach 109° F. In uræmic convulsions, in either man or woman, the temperature becomes subnormal. It is to be remembered that there is an undue excitability of the nervous system during pregnancy. Some yet unknown toxine which the system is unable to eliminate so stimulates the nervous centres as to throw them into a paroxysm of confusion. Not only in the kidneys are to be found changes in connection with eclampsia, but the blood vessels of the lungs, liver, and brain are shown to be highly thrombosed. However caused, it is seldom that an attack occurs without first showing certain premonitory symptoms. The patient will usually be somewhat drowsy and complain of headache. This headache may be limited to one side. Impaired vision, spots before the eyes, and intellectual dullness are frequent precursory symptoms. These last out for a short time, when the patient is seized with general tonic spasms. This is quickly followed by violent clonic convulsions which whirl the unfortunate victim into a precipice of danger that contrasts in awfulness and suddenness with the peace and serenity of her previous condition. The great nervous centres reel, rock, and splutter, form centres of delirium, the eyes roll up under their lids, the features are unrecognizable and the mouth is twisted into horrible grimaces. Should the onset of convulsions be delayed until the end of pregnancy and delivery speedily follow their supervention, it is quite probable that the child may survive. If there is any delay between the attacks and delivery, the child almost uniformly perishes. In those cases in which eclampsia comes on before the completion of pregnancy, the fœtus is seriously impressed by the first, and nearly always perishes after the second or third attack. The cause of death to the fœtus is attributable to the condition interfering with the hæmostasis of the blood, and indirectly producing asphyxiation. When the mother dies during the last stages of labor, it is not advisable to endeavor to save the child by Cæsarean section, for it will be found to be dead.

Phthisis.—For some unexplained reason, there is a fertility among this class of pregnant women which may be considered abnormal. The tendency to abortion in phthisical women, although admitted not to be particularly striking, is nevertheless greater than in healthy women. The degree of vitality and the measure of endurance of a fœtus, or a living child for that matter, bears a close relationship to the degree of strength or

exhaustion of the mother at the time of conception, and to the condition of her health during pregnancy. For a time the profession entertained the opinion that pregnancy arrested the progress of this disease, but the hypothesis was not well founded. It is quite probable that during the early weeks and months of pregnancy the progress of this disease appears to be held in abeyance. This is no doubt due to the increased nutritive impulse which is given to the system generally; but when the fœtus assumes a large size, there are naturally greater demands made upon the nutritive resources of the mother, and, as a consequence, her vital energies are put to such dire straits that the disease then advances much more rapidly. It is asserted that when gestation takes place in a woman already well advanced in phthisis, and a child is born, a future pregnancy but rarely goes to the full term.

Heart disease is a much more serious condition in pregnancy than phthisis. The disease is much aggravated during pregnancy and there is a great liability to shorten gestation. During the earlier period very little disturbance is appreciable, and it is not until midway in gestation that signs of distress appear. It is quite reasonable that this should be so. In valvular disease, the leaking valve allows a certain amount of blood to regurgitate, and as a consequence the heart is laboring under a great disadvantage. Compensatory enlargement follows, and a sort of unstable equilibrium becomes established. When pregnancy is advanced, a corresponding increase of power and force is demanded of it to meet the necessities of the incessant nourishment to the fœtus. Compensation is, by this new demand, again unbalanced, and the condition becomes much aggravated. From the general backward pressure of blood, the liver, kidneys, and lungs assume a condition of passive congestion. When this reaches a certain limit, the whole nervous system participates, with the result that transudation takes place, followed closely by albuminuria, enlargement of the liver, and general dropsy. There will be congestion of the pelvic circulation; defect of aeration of the maternal blood, which may so affect the uterine circulation as to cause the death of the fœtus.

Syphilis.—When speaking of the causes of intra-uterine death produced by conditions referable to the father, we had occasion to mention syphilis as one of the most frequent and pernicious. We will now proceed to consider its adverse influence so far as the mother is concerned. A controversy has arisen as to whether a healthy woman who marries a man tainted with syphilis can be contaminated through the father or the fœtus. Fournier maintained that such a man, if afflicted with the third stage of the disease, could not contaminate his wife. Neither would the fœtus of such a pair taint the mother until after its death in the uterus. His reasonings are probably not well founded, for reasons which we will consider shortly. If the mother is syphilitic before conception takes place, the offspring almost invariably

becomes affected by the poison. Anatomically and physiologically, there is a constant and intimate relationship between the mother and child during the whole period of gestation. The mother supplies it with nourishment and oxygen to develop its various structures. True it is, that though there is no direct vascular communication between the membrane intervening between the vessels of the mother and the small loop-like projections of the foetus, the membrane is so thin that the necessary ingredients for the nourishment of the foetus pass through readily and constantly, probably by osmosis. The white blood corpuscles are supposed to be the agents conveying the infection. It is known thoroughly well that these cells possess the power of penetrating such a thick wall as that of the vessels in which they normally dwell. They will then, with greater ease and comfort, be capable of penetrating through the utero-placental circulation. It would seem that this was so. The white blood corpuscles can without doubt convey material substances from the mother to the foetus. This has been demonstrated by experiments upon lower animals. Pregnant animals have been injected with such substances as cinnabar or indigo, and, when killed shortly afterward, the white corpuscles in the foetuses contained the particles injected into the blood vessels of the mother. We have already seen that when a pregnant woman contracts small-pox she can convey the disease to the foetus, and that the foetus is frequently found to have the pustules on the skin. If it is possible for the blood of the mother to convey to the foetus substances like cinnabar or the germs of small-pox or scarlet fever, we may conclude without any hesitation that the morbid virus of syphilis can be similarly transmitted. The necessary elements for the growth and development of the embryo transude: why not the stealthy, insidious germ of syphilis? The uterine sinuses may be considered the trysting place for the foetus to exchange its excreta for nutritive elements. For practical purposes, it is immaterial whether or not there is an immediate or indirect vascular communication between the mother and her child. It is fairly well established that either parent may infect the foetus independently. When the virus in either the father or the mother has exhausted itself and has become attenuated, it is quite possible for a viable child to be borne. There will, however, very likely be evidences of perversions of growth or other defects noticeable. It is well established that the mother may beget a syphilitic child long after she has ceased to show any evidence of the disease herself. Whether transmitted by the father or the mother, syphilis remains one of the most frequent and fatal diseases, so far as the foetus is concerned. Where the infection is active, its impression upon the ovum causes it to blight early in the course of uterogestation. When the virus is not so concentrated, the foetus may go on developing for a time, but ultimately hæmorrhagic effusions may take place between the foetal envelopes, and so cause a detachment.

Hæmorrhagic, waxy, and other changes take place in the placenta, and so interfere with the nutrition of the foetus as to cause it to perish and be cast off. In these unfortunate women, abortions follow each other in frequent repetition, and apparently with undeviating persistency. Even where there are no external or other evidences of the malady, a succession of abortions or dead children can be traced to a latent form of this disease. When they are placed under a systematic line of antisyphilitic treatment for a sufficiently long time, the tendency to abortions disappears and pregnancy goes on to the full term. The unfortunate feature of this mischievous and insidious disease is its persistent and extended lethal influence. It is exceedingly difficult to determine when its poisonous effect will expend itself. Occasionally it happens that after all signs of the disease disappear from one or both parents, they still continue to produce abortions, dead children or living children showing by their emaciation that the venereal taint is not yet fully eradicated. The public generally know but little of this insidious and noxious disease, and of the ill effects it may produce upon numberless unborn children and women absolutely innocent of any trace of immorality. If they did, the evil consequences that too frequently follow in the wake of this loathsome disease might not be so frequently propagated.

(To be continued.)

THE ELECTROCHEMICAL ACTION OF THE X-RAYS IN TUBERCULOSIS.

By J. RUDIS-JICINSKY, A. M., M. D., M. E.,

CEDAR RAPIDS, IOWA,

SECRETARY OF THE RÖNTGEN SOCIETY OF THE UNITED STATES; MEMBER OF THE INTERNATIONAL CONGRESS OF MEDICAL ELECTROLOGY AND RADIOLOGY, PARIS; OF THE AMERICAN MEDICAL ASSOCIATION; OF THE WESTERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION, ETC.

SINCE 1896 I have reported a few cases of lupus cured with the x-rays (1). It has long been known that the rays of light (2) were the most powerful bactericide known, and the work done by the investigators and experimenters with the x-rays shows that their effect upon some bacteria is of a marked electrochemical character; so that we may have in the near future another field of investigation, in regard to tuberculosis pulmonalis, which still remains the disease most to be dreaded.

What is the ætiology of lupus vulgaris? It is supposed to be due to the presence of the tubercle bacillus in the skin. The local treatment aims to destroy or remove the affected areas. To this end various measures are recommended, the x-ray treatment being the latest and perhaps the most successful. In my cases, at least, it has given satisfaction when all other methods had failed.

Knowing this, and thinking of the destruction of the bacilli in the living structure, with the proper immuniz-

ing of the organism against the effects of the bacilli, I have been independently experimenting for the last four years, pursuing my own way in the direction of solving the problem of possible cure of the diseased condition by removing the exciting cause of consumption.

Is there a cure possible? Naegeli divides his 217 cases of non-fatal tuberculosis into 74 cases of active disease, 111 healed cases, and 32 which he regards as uncertain (3). One hundred and eleven cases out of 217 were healed, and this information about the curability of tuberculosis comes directly from the *post-mortem* room, the only tribunal for definite and possible determination.

With the cases of lupus, it seems to be fully demonstrated that the *Bacillus tuberculosis* can be destroyed locally with the x-ray, or that necrosis of healthy tissues caused by exposure to the rays renders the parts unsuitable for the growth of the bacilli. If this can be done externally upon the skin, why not bring the rays into direct contact with those parts of the diseased lungs which the fluoroscope or a skiagraph marks as tuberculous? We know that the infecting agent of tuberculosis is the tubercle bacillus (4), that this disease cannot exist without it, and that when it is present it is invariably given off when the disease has progressed far enough, in the form of broken-down tissue, in the sputum. A consumptive expectorates at times as many as 7,000,000,000 bacilli in twenty-four hours (5). From this fact the nature of the first step of our experimentation was not difficult. With the help of the microscope, the presence of the bacilli in the sputum was determined; a certain quantity of the sputum was placed in a fish-bladder filled up with veal bouillon containing two per cent. of peptone and two per cent. of glycerin, and closed, and the whole properly boxed and marked. Each box was then alternately exposed to the x-ray, giving one case treated with all the opportunities for constant growth of the bacilli that a private laboratory allowed.

Before exposure to the x-ray, I made stroke cultures on glycerin agar from each box named, and kept the same in the brood-oven for ten days at the temperature of 37° C. These preparations, agitated once a day, showed under the microscope a thick, curled-up centre around which threads were wound, with the bacilli in profusion. These pure cultures, with others of anthrax bacillus, streptococci, staphylococci, and the bacilli of cholera, typhus, and diphtheria, were also alternately exposed to the x-ray, and the results of these two experiments showed that certain x-rays were similar in their actinic properties to the rays of light at the violet end of the spectrum, and that various bacteria reacted under such radiation differently, according to the quality of the plasma and the degree of the liquid they contained. With mildly alkaline culture media, the propagation of *Bacillus tuberculosis* is secured and the growth of the germs accelerated by the influence of an x-ray tube, but in acid media the *Bacillus tuberculosis* is rendered inert:

UNDER X-RAY RADIATION.

	Media.—	
	Acid.	Alkaline.
<i>Bacillus anthracis</i>	Negative.	Negative.
<i>Bacillus tuberculosis</i> , in sputum, destroyed. . . .	48 minutes.	Negative.
<i>Bacillus tuberculosis</i> , in flask, destroyed.	50 minutes.	Growth accelerated.
<i>Spirillum cholerae</i> , in flask, destroyed.	51 minutes.	55 minutes.
<i>Bacillus diphtheria</i> , in flask, destroyed.	46 "	48 "
<i>Bacillus typhi abdomi-</i> <i>nalis</i>	45 "	49 "
<i>Streptococcus</i>	Negative.	Negative.
<i>Staphylococcus</i>	Negative.	Negative.
<i>Micrococcus pyogenes al-</i> <i>bus</i>	Negative.	40 minutes.
<i>Micrococcus gonorrhœa</i> . .	35 minutes.	49 minutes.

The third step taken was to inoculate ten guinea-pigs and ten rabbits from the foregoing cultures. Beginning with the tenth day, they were all exposed to the x-ray daily. Eight of these animals whose secretions were rendered alkaline, six guinea-pigs and two rabbits, died of tuberculosis; the others inoculated from the box with acid media, having been in the first stage of tuberculosis—so to say—and exposed to intense irradiation daily for ten seconds, were, under observation, living and seemingly in good condition, for two years.

The bodies of the six guinea-pigs and two rabbits were dissected. In all these cases we found cheesy transformation, lungs undergoing destruction, with cavities; in the walls of some of the bronchioles, semi-solid granulation, tuberculous. The apices and the opposite upper lobe gave marked traces of the process of repair, showing plenty of more or less structureless connective tissue without cheesy material. In the majority of the cases we had obliteration of the pleural cavity. In two cases, depositions in the brain, one in the liver and the intestines. In forty per cent. of the animals treated with the x-ray and killed after the lapse of two years, the *post-mortem* examination showed that actual cure of the tuberculous process has occurred in the real sense of the word when acid condition was produced. Giant cells were not found, but there were chalky masses enclosed in dense tissue, connective tissue, and adhesions, without the *Bacillus tuberculosis*.

It is not necessary to demonstrate any further that the rays penetrated deeply into the tissues of all the bodies. Every skiagraph of any part of the body is a sufficient proof of it, and the experiments, as we were able to show, gave us the opportunity to observe also the electrochemic action of the x-rays almost to their point of penetration.

The discovery of the *Bacillus tuberculosis* was the first great step in medicine. The recognition of the fact that tuberculosis is a contagious disease was the second. The next important step forward, since the discovery of the ray by Professor Röntgen, is surely the very important application of the x-ray in connection with the

early diagnosis of tuberculosis. Keeping in mind that a very large proportion of those affected with tuberculosis may recover their health under proper treatment, or their life may be prolonged (6) if the diagnosis is made in time, we shall find in the application of the x-ray a great help to us (7). Abrams says (8): "The results of treatment in special sanatoria for pulmonary tuberculosis are marvellous. From twenty-five to forty-two per cent. of cases are cured." The diagnosis with the x-ray is not difficult. But the next step is yet to come. It is to be hoped that this step may mean the recognition of the method of cure with the yet unknown ray, when it comes to be known to all of us.

Satisfied with the results of my experiments described above, I have in the last two years, with the patients' consent, applied the x-ray in every case of earlier stage of tuberculosis which I have had, or which has been sent to me for diagnosis. Nearly all these cases, giving, on x-ray examination, a slight haziness, indicating the beginning of tuberculous infiltration in the apices, I have treated accordingly, attacking the seat of the disease, and not forgetting the three most important factors—pure air, suitable temperature, and good hygienic surroundings. From twenty selected patients in one year, one died with tuberculous intestinal complication, another committed suicide after two sittings, four proved complete failures, and the rest are doing comparatively well.

The exposure varied with each case from ten to fifteen minutes at each sitting. The rays have to be observed with the fluoroscope at each exposure, the tube tested to see that it is working at its best, and the apparatus will also be under the full control of the expert, who, with the help of the x-ray, will not only determine what portions of the tissues are diseased, but locate the area over which the disease extends, and ascertain what changes have taken place since the first exposure. The treatment ceases with the induction of a favorable condition of the patient, and when the lungs give us upon the plate of the fluoroscope an image of shadows of new-formed adhesions—which are opaque to the x-rays—in a transparent field of healthy tissues. Remember that healthy tissue allows the x-ray to pass freely, and thus we may record the changes, situation, and the size of isolated foci also.

The patient is seated in a chair without a back, and the Crookes's tube held from fifteen to eighteen inches from the body, directly in line with the diseased spot, as shown on the screen of the fluoroscope in the front, which must be applied firmly, and to the bare chest if necessary. At the next sitting the procedure is repeated, the Crookes's tube being in front. The proper distance between the light and the screen is about thirty inches, but this depends altogether upon the character of each given case, and may be gradually extended or diminished. It is very difficult to find just the length of exposure to make in these cases. If the exposure is not

made long enough and at regular intervals, the desired result is not obtained, and if it is too long, it may set up an inflammatory action which may cause hæmorrhage from the irritated lung tissue and weakened vessels, and accelerate the growth of the bacilli instead of destroying them. In other words, the diseased tissue of the lungs is of such a low vitality that the influence of the x-rays may cause its absorption, or even destruction, before having any marked effect upon the healthy tissue.

While the removal of the bacilli, or, rather, of the cause, is essential to permanent cure, it is well—I am speaking of earlier stages only—in order to retain the patient, to institute some measure to support the nutritional changes in the healthy part of the lung tissue with increased metabolic change, stimulating more rapid and complete oxidation of the blood; and nothing has answered so well in my cases as static electricity, which may be used alternately with the x-ray. Such static electrization tones up the patient for the next x-ray exposure, and, with all the other hygienic and therapeutic measures necessary, according to the symptoms, will give Nature an opportunity to deposit healthy lung tissue, so that repair may take place. The great function of the x-rays—and, in my cases, the results so far obtained are very encouraging—is to destroy the bacilli directly in the lungs, while the franklinization improves and restores nutrition, not only of a part, but of the whole (9). By such a process of treatment the healthy tissue is kept immunized on one hand, and, on the other, the further proliferation of the bacilli is stopped. The majority of our patients improved, the bacilli disappeared from their sputum, the night-sweats ceased, and now the patients do not cough; they say that they feel better and are restored to usefulness. But *I should not like to state that the cases were cured by the x-ray exposure only*, for it may have been spontaneous cure in all of them. They are, however, certainly now well, and are feeling in good condition; and also just as certainly they had tuberculosis pulmonalis when the treatment began.

As to the danger accompanying the use of the x-rays, I have to state, and can prove it from my experimental work, that there is absolutely none, when proper care is taken. During the actual daily applications of these rays to my patients for diagnostic and therapeutic purposes, I have not had one case of dermatitis or necrobiosis (10) of my own, and, if certain precautions are taken, proper apparatus is used, and exposures are not unnecessarily prolonged, the danger of too intense action of the rays will be avoided. At the first trace of slight burning sensation or itching, or of brownish coloration of the skin, the treatment must be stopped at once. It must be certainly employed systematically to secure some results, because the x-ray may act, not as a stimulant as desired, but as an irritant, not only giving all the inflammatory phenomena at the focus of irritation, but spreading, perhaps, over a large continuous surface, with changes directly dependent upon the disturb-

ances of the circulation. It is clearly apparent that, if the x-ray in sufficient strength and proper form is made to reach the tubercle bacillus in the living tissues, its destruction may follow, and it remains for us to demonstrate these facts, not only theoretically, but clinically. The employment of the x-ray in cases of phthisis pulmonalis is worthy of extended trial. This is a practical question, which, with a practical test, will show us whether we have finally found the weapon against this baneful scourge and can put an end to the spread of the terrible and deadly contagion. Let us have a number of establishments where this work can flourish, sanatoria, public and private, which would do a world of good by curing the curable tuberculous cases and taking care of the hopeless ones, thus diminishing the countless centres of infection.

THE PALLIATIVE OPERATIVE TREATMENT OF CARCINOMA OF THE POSTERIOR WALL OF THE STOMACH.*

By ALBERT VANDER VEER, M. D.,

ALBANY, N. Y.

To the surgeon who has been a close observer of, and participant to some extent in, the advances that have been made in abdominal surgery during the past two decades there has come much to gratify and encourage the efforts put forth for the relief of patients suffering from malignant growths of the stomach. All of this work has demonstrated the fact that operations for resection of portions of the stomach, and even its entire removal for malignant growths, have in many instances proved a success as regards the saving of life, or, to say

the least, in the prolongation of and making a patient's existence more comfortable.

For a time operations were confined, more particularly, to the pyloric end of the stomach, and were limited; but gradually surgeons have grown more and more dexterous, and, while cases are rare which permit of entire removal of the stomach, yet there are many in which after a careful examination a resection can be done, and an anastomosis, when the surgeon is called too late to grant relief permanently. The case may be one in which there is little hope of complete removal of the growth, yet the patient is suffering greatly, is desirous of some relief, if possible, and in many instances voluntarily encourages the surgeon to make an exploratory incision to learn positively just what can be done for his comfort. It is to this class of cases I wish, more particularly, to direct the few moments assigned to this paper. Up to within a very few years, as surgeons we were sometimes obliged to say to our patients, after an exploratory incision, that conditions were found such as prevented a removal of the growth, and that we were forced to retire from the field of operation without granting any relief. Gradually, however, these cases have been brought under the control of the surgeon to the extent that some form of intestinal anastomosis can be done, so as to give our patients decided relief for a time well worth the effort, and the patient and friends have, later on, entered heartily into the endorsement of such a line of treatment, because of the good results.

By degrees pathological changes, of whatever nature, have been brought by the surgeon to some form of operation, and in many instances the most brilliant work of modern surgery has accomplished that which a few years ago was considered quite impossible. Beyond a doubt, early operation on the stomach, for the relief of malignant growths, brings the best recoveries.

Yet, notwithstanding the many operations that have resulted in perfect recovery, and in many instances the prolongation of life, still some few cases are so obscure in the development of the history that the tumor, in the form of malignancy, is allowed to grow quietly, evading every effort of diagnosis made possible by the attending physician. When, too late, the surgeon is called, he then realizes that, while there can be but little hope for a radical operation, yet something can be done for the comfort of the patient, and the manner and method of doing this little have earnestly engaged the attention of the operating surgeon, making it a subject worthy of record and of some discussion. The present situation is one that impresses us with another illustration of the fact that in many ways it is necessary for the physician and the surgeon to work hand in hand.

Take, for instance, the great advances that have been made within a few years by the physician in the examination of the secretions of the stomach, either in the form of vomit, removed as a test meal, or otherwise. How great have been the rapid strides in a more careful

*Read before the Third Pan-American Medical Congress, held in Havana on Monday, Tuesday, Wednesday, and Thursday, February 4, 5, 6, and 7, 1901.

diagnosis brought about by the chemical, bacteriological, or other examinations, as to the presence or absence of free hydrochloric acid, or many manifest signs of malignancy, such as loss of appetite, emaciation, reduction of the hæmoglobin in the blood, progressive to sixty-five per cent. or under, and a moderate leucocytosis that may be present, and when recognized early by the attending physician he should, without delay, call upon his consulting surgeon.

As was once the history in appendicitis and other obscure abdominal conditions, the two members of our profession must unite their efforts, and do early and promptly what is to be done for the relief of this particular patient.

This is what I wish to emphasize thoroughly, that when once a suspicion or a positive belief is expressed by the family physician of malignant growth of the stomach, the surgeon should be made acquainted with the condition of the patient, and the possibilities of relief by surgical intervention must be considered.

It is probably quite true that only a small percentage of these cases, where there is a suspected malignancy, are allowed to go on to any great degree, in surgical centres, without the surgeon being consulted, yet it is in some forms of growths about the posterior wall of the stomach that we see the most serious complications presenting. It is in this class of cases, I believe, that the operating surgeon—at least my own experience has been in that direction—finds the most serious complications of involvement of the glands and adhesions, making it impossible to remove the diseased mass, and yet we are permitted to do much that will relieve the patient, particularly when the disease has advanced toward the pyloric end of the stomach, causing a stenosis that brings with it all the symptoms of distress, first called dyspepsia; then, as vomiting occurs, the possibility of some malignant growth dawns upon the physician and patient.

I am satisfied that these patients can be made comfortable, in some instances for many months, possibly but a few weeks, and yet are so decidedly relieved from suffering that the operation of gastro-intestinal anastomosis should be encouraged. So convinced am I of the good to follow an exploratory incision, in the most serious cases, that, though "lactic acid may be present; the Oppler-Boas bacillus, and the epigastric tumor," yet I would not deny the patient the slight chance it may offer for his greater comfort to follow. It is here, in this operative intervention, that we note the marked advances that have been made within a comparatively short time in the method of doing the operation.

Let me illustrate:

CASE I.—MR. F., fifty years old, had suffered for over five years from symptoms of stomach disturbance, and had had many diagnoses given him. For a period of two months he was under my observation at the Albany Hospital, suffering much from severe pain and vomiting frequently. By various tests and examinations—the clinical history being taken into consideration—

it was evident he was suffering from some growth in the posterior wall of the stomach and encroaching upon the pyloric end. I advised an exploration, to which he readily consented. I found a growth measuring nearly four inches at its longest diameter and two inches in width, fastening the lesser curvature of the stomach to the connective tissue posteriorly, and somewhat above the common bile-duct, yet well underneath the diaphragm. The extent of the growth and its many attachments made it impossible for me to remove any portion or in its entirety. "The lymphatics and lymph nodes, so well defined by Cunes and Most as associated with carcinoma of the stomach," were here well shown.

I made a direct anastomosis of the extreme upper end of the jejunum with the anterior wall of the stomach by means of the Murphy button, the button passing after the twentieth day. After the operation the patient was nourished by rectal enemata entirely for a period of thirty-six hours, then small quantities of matzoon were given every two hours, and at the end of the third day he was given milk, broths, and liquids quite freely.

The result in this case was most gratifying; the patient could taste and enjoy his food, and was better in every respect. He gained in flesh, but about every three weeks he would have attacks of nausea and vomited quite a good deal of greenish-looking fluid, having all the appearance of bilious material. He would then be better for a while, but during these attacks the pain was quite severe and required hypodermics. The patient continued in this condition for a period of over eight months, not emaciating and taking food very well. He then moved to another State and I lost track of him.

I had studied this case carefully as to the cause of the vomiting at times, and believed it to be mechanical from some defect in the manner of anastomosis, when my second case presented.

CASE II.—MR. C. N. G., fifty-two years old, married; habits good and regular in every respect; grocer by occupation; normal weight, 240 pounds. Past history: Patient always well until three years ago. Family history, negative. He stated that a little more than three years previously he began to have attacks of vomiting, at intervals of from two weeks to a month, usually coming on at night. Pain very severe and well localized in the centre of the epigastrium, being very noticeable at this point. As it grew more severe he usually vomited a large amount of mucus and undigested food. During the past two years these attacks have gradually grown more and more frequent, and for the past four months have occurred almost every night. Once or twice he has vomited some clotted blood. He has lost fifty pounds in weight. The epigastrium was very tender on pressure. Physical examination did not reveal any evidence of disease elsewhere about his system, and examination of the blood showed only a moderate amount of leucocytosis. Tests for hydrochloric acid indicated a moderate amount. On deep pressure over the epigastrium, a thickening could be felt, but not a distinct, well-formed tumor. I advised an exploratory incision, to which he readily agreed, saying most emphatically that he could not live long in this condition, and, if possible, he would like relief, preferring death to his present existence.

The operation was done January 30, 1900, at the Albany Hospital. The usual incision was made, and

the condition found very much like that described in the first case, but I did a somewhat different operation. Finding it impossible to do a resection of the stomach, or to remove the mass, which was so firmly attached posteriorly, I made an opening through the mesentery, so as to reach the posterior wall of the stomach, well toward the left, then brought up the upper portion of the jejunum, about twelve or fifteen inches from the duodenum, made an opening into the intestine, passed the medium-sized Murphy button down, one portion toward the duodenum, another portion toward the ileum, and, after bringing the button together (this suggestion was made at the time by my assistant, Dr. Macdonald), attached the jejunum by silk sutures to the posterior wall of the stomach.

After the operation the patient was treated very much in the same manner as in Case I, a hypodermic of morphine being given him to control pain. There was very little vomiting, and at the end of the fourth day he expressed himself as feeling better than he had in a year. He could swallow fluids without their giving him any distress, nor did he have any return of his pain at night. The nurse was instructed to watch his stools somewhat carefully, but along about the twentieth day a pupil nurse was on duty for part of the day, and one or two stools were lost without being carefully examined. Although the examination of the stools was kept up for some two months afterward, yet he was never known to have passed the button.

This patient did not have any return of his vomiting, he could take some little food and any amount of liquid nourishment, and at the end of four months had gained twenty pounds in flesh, having good movements of the bowels, and in every way was very comfortable.

I believe that the direct tract made here between the duodenum and the jejunum permitted the bile and pancreatic secretions to pass directly into the intestinal tract without regurgitating, or backing up, as it were, into the stomach, and saved this patient from the attacks our first patient had, even after the anastomosis. This patient is yet living and in very good health; he is able to attend to his business, and, although during the past four months he has vomited two or three times, which he attributed to the kind of food he had taken, yet in every way he has been very comfortable, and certainly his life has been prolonged and made bearable. On January 30, 1901, this patient is looking and feeling well in every way.

CASE III.—Mrs. H. L., forty-one years old, married, mother of five children. Family history, negative. Never had any serious illness; menstruated normally; but for the past four months has been unable to eat solid food and retain it. Has occasionally had attacks of vomiting, not of large quantities, but accompanied with considerable pain, with more or less pain during the past two years, in the intervals between her attacks. For the last three or four months she has rapidly grown worse; lost very much in weight, had pretty continuous pain, been unable to take even liquid food into the stomach, and had very severe pain in the left shoulder at times.

At this time the patient weighed about one hundred pounds. On direct physical examination, she presented

no evidence of disease elsewhere, except in the region of the epigastrium, where pain on pressure was very pronounced, and an immovable tumor could be located. I advised her husband and herself to have an exploratory incision in her case, an opinion in which her family physician, Dr. Trego, readily concurred, and let us see what we could do for her relief.

An operation was done at the Albany Hospital on May 23, 1900, in almost precisely the same manner as in Case II. The growth was found to implicate more of the pyloric end of the stomach, also the posterior wall quite markedly, and reaching back toward the head of the pancreas and pressing on the common bile-duct. At first I thought possibly I might have a case of gall-stones to deal with, but it was unmistakably a carcinoma of the posterior wall of the stomach. Her treatment was precisely the same as in the other cases. She passed the button on the seventeenth day, and has been perfectly free from suffering since the operation. She has gained twenty-five pounds in flesh, can take almost any amount of nourishment, and does not know but the diseased mass was entirely removed; is happy in her make-up, and is certainly being made very comfortable for one whose disease is so serious.

CASE IV.—Mr. S. W., fifty-three years old, a German, married. His father died of tuberculosis; six sisters and two brothers are alive and well. He had pneumonia twenty years ago, from which he made a good recovery, and remained well until his present trouble began, about four months ago. For a time he had diarrhoea, followed by very marked constipation. At this time gas began to form in his stomach and intestinal tract, and gave him a great deal of trouble. He got into the habit of making eructations of gas as the stomach became distended, and this afforded him relief. No pain; usually sleeps well; appetite not good. Was unable to take solid food and only cared for broths. He had lost thirty pounds in four months. Complains of a dull, heavy feeling in the region of the stomach. States that he was examined by Dr. E. T. Rulison some three months ago, and his stomach washed out. In a communication from Dr. Rulison, he stated he had examined the contents of the stomach and found a decided absence of hydrochloric acid, but there was lactic acid present, and the test meal was undigested. The doctor advised an early exploration, but this the patient declined.

Mr. W. was sent to me by Dr. Louis Faust for operation. On direct physical examination, the patient appeared emaciated, skin and membranes pale, heart and lungs normal; slight tenderness over the stomach on deep pressure, but no tumor could be made out. Urine normal on examination.

January 8, 1901.—Blood examined by Dr. Cooper-nail, of the house staff: Hæmoglobin, 65 per cent.; leucocytes, 11,440; red cells, 4,200,000. The patient was ready and anxious for an operation, stating he could not get on and nourish himself unless he received aid in some way.

9th.—A. C. E. mixture and ether administered. The usual incision was made and the tumor found to be of the size of an orange, involving a portion of the pyloric end of the stomach and the posterior wall, also the glands adjacent thereto. It was difficult to lift the growth forward free to any extent, and upon very thorough examination it was found impossible to make even a resection of the stomach. A gastro-intestinal anastomosis was done between the upper portion of the jejunum

and the left posterior wall of the stomach, the Murphy button being used for the lower anastomosis. The wound was closed by layer sutures; standard dressing. The patient suffered severely from shock. He was given strychnine and nitroglycerin hypodermically, also an infusion of nearly a quart of normal salt solution while on the table. While the operation did not consume more than the average time, yet he was kept upon the table for an hour and ten minutes. He had then revived sufficiently to be taken to the recovery room, and hypodermics of strychnine and nitroglycerin were continued every four hours. He rallied well during the night, becoming thoroughly conscious, and the kidneys secreted in a normal manner. In every way his treatment was about the same as in the previous cases.

This patient became very cheerful and hopeful after the operation, and on the evening of the third day the house physician telephoned me that Mr. W. complained of being hungry, and if he did not get something to eat he would get out of bed and help himself. He was given milk and broths quite early during the third night after the operation. Since then he has continued to take liquids, then semi-liquid food, and now he can enjoy eating almost anything. His bowels were moved on the fifth day by slight laxatives and the use of rectal enemas. He was looking much better, and was able on the fourteenth day to sit up out of bed, the wound being entirely healed.

Although I did not incise this growth, yet I am satisfied from the feel and appearance of it that beyond a doubt it was carcinoma of the posterior wall of the stomach, gradually invading the pylorus, the latter not yet stenosed, which unquestionably accounted for the absence of vomiting.

I believe these cases are of such importance that we may gather some practical points.

1. I would say that, in all cases of continued gastric disturbances that do not yield to medical treatment, a careful examination and experiment should be made as to the possibility of malignancy being present.

2. That, whether a positive diagnosis of malignancy is made or not, the patient continuing to emaciate, suffering more and more, I believe an exploration should be done, and if there is no malignant growth a gastro-intestinal anastomosis should be made, along the lines suggested by Dr. Weir in his excellent paper, and which I have done with the happiest results.

3. That malignant growths in the posterior wall of the stomach are certainly more difficult of diagnosis, and sometimes escape the notice of the most careful diagnostician.

4. That when we have made an exploratory incision, and the growth is found to be in the posterior wall of the stomach, malignant in character, with no possibility of removal by resection or otherwise, although quite deep, yet I believe we should not refuse our patient the benefit of a gastro-intestinal anastomosis.

5. In all of these cases the blood should be carefully examined, as part of the history of the patient, in order to learn of such conditions as may have a bearing upon the nature of the growth.

28 EAGLE STREET.

CANCER OF THE UTERUS.*

By ANDREW F. CURRIER, M. D.,

NEW YORK.

LIKE cancer elsewhere, this disease is well defined in Waldeyer's concise terms as "an atypical epithelial new growth."

All attempts to prove cancer to be a germ disease have thus far failed, but it is by no means certain that a germ will not ultimately be found as its primary cause.

Like tuberculosis, it attacks certain families in certain locations, and a cancerous family history is not without importance in determining the diagnosis and the outlook in a given case.

Traumatism is an important factor in the determination of the disease, though the unavoidable lesions of the os uteri in connection with parturition have probably played a more important part in its ætiological history than they really merit. The errors and imprudences which often follow parturition may have much to do with the bad condition of the tissue of the uterus which predisposes to cancer.

The poor are apt to suffer from this disease more often than the rich, for they must work harder, have fewer comforts and luxuries, and can pay less regard to their physical well-being and nutrition. So far as we can obtain definite information, this is a disease of civilized rather than savage life, though it is not unknown to the latter.

Climatic conditions may have a certain influence; the crowded cities are more favorable to its appearance than the country.

In order of frequency, the disease attacks the breast, the stomach, and the uterus.

No particular line of conduct or treatment, other than that which is associated with a well-regulated life, can be looked upon as prophylactic for this disease, and this will by no means bring immunity in all cases. For women who have a bad or suspicious family history it is wise to submit to a rigid surgical inspection at intervals of from three to six months, a radical surgical operation being urged on the slightest appearance of definite malignant disease.

Women with a tendency to this, as well as any other serious constitutional disease, should also be discouraged, by every possible argument, from becoming impregnated.

The disease may begin upon the flat epithelium of the surface of the mucous membrane or the cylindrical epithelium of the glands. It may attack the vagina, either lip of the os uteri, the endometrium of the cervix, or the endometrium of the corpus uteri. The softer the tissues invaded the more rapid its extension; in other words, its progress is along the lines of lesser resistance. The more rapid the development of the disease the greater the vascularity of the tissues and the consequent tendency to necrosis and hæmorrhage. The dis-

*Abstract of paper read before the Pan-American Medical Congress at Havana.

ease elements may be transmitted by the lymphatic current to other tissues and organs, and the absorption of infected material and frequent losses of blood will be followed by marked wasting of the vital forces. The density and great resisting power of the lymphatic gland structure explain the rather infrequent metastatic phenomena, this being especially true with the aged, in whom the glandular system is inactive. The disease is sometimes seen between the thirtieth and fortieth years, more frequently between the fortieth and fiftieth, most frequently between the fiftieth and sixtieth, and quite rarely after the sixtieth year.

The influence of the change of life upon this disease has been much misunderstood. It is probable that it has little, if any, influence in its production. The first noticeable symptom is hæmorrhage, which sometimes occurs in connection with the monthly periods and sometimes in the intervals.

Too often such a note of warning remains long unheeded. If the os uteri or the epithelium of the vagina is first attacked, a superficial ulceration, which resists the substances that usually produce healing, will be observed on careful inspection. This is followed by spreading, infiltration, and breaking-down, with hæmorrhage and discharge of decomposed and very offensive material. The longer the interval between the hæmorrhages, the severer and more copious are they likely to be. A hæmorrhage following sexual intercourse may be the first decided intimation that a serious condition exists. In addition to hæmorrhage from the uterus, it may also proceed from the vagina, rectum, and bladder, when these organs have been invaded.

Pain is an important symptom, but is seldom present in the early history of the disease, and it may be absent until the end. It may be felt not only in the uterus, but in the ovaries, broad ligaments, bladder, rectum, intestines, and kidneys. The skin of the external genitals may become excoriated and sensitive.

Cachexia, or sallowness of the skin, is a frequent, but not a necessary, complication. There may be a similar appearance with almost any wasting disease. Emaciation usually occurs if the disease is of long duration.

Disease involving the cervix is much more frequent and much more rapid in its progress than that which first attacks the body of the uterus. The structures to which this disease most frequently extends, in addition to the pelvic viscera, are the peritonæum, retroperitonæal glands, including those of the mesentery and omentum, the ureters, and the kidneys.

The corrosion of the vagina, bladder, and rectum, converting all into one cloaca, forms a distressing feature in the late history of the disease. The rectum may be nearly or quite occluded by cancerous ingrowths.

If the disease is observed or suspected in an early stage, examination with the microscope of a portion of the tissue or of scrapings from the endometrium may reveal the situation. Repeated examinations at short

intervals should be made if the condition is one which admits of doubt.

In the advanced stages of the disease the clinical diagnosis can hardly be mistaken. The disease is local at its inception, and often remains so for a long time.

When once the existence of cancer has been determined the radical removal of the organ must be effected as soon as possible, provided its removal is still possible, and the situation in each case must decide whether the avenue should be the vagina or an abdominal opening.

The ligation of the great vessels of the pelvis has not thus far led to results which seem to warrant the procedure, except in particular cases.

The free use of the actual cautery upon tissues which may be deeply infiltrated is often effective. The potential caustics, chloride of zinc, nitric acid, etc., are often useful, but should be employed with the greatest caution, as they cause great pain, may excite intense inflammation, and may injure tissues which should not be injured. None of the substances which have been recommended for injection into cancerous tissues seems to have been of very great or permanent value, unless used at a very early period. Palliative operations, scraping, cauterizing, packing, douching, if used intelligently, may bring great, if only temporary, relief. Diet and hygiene should also play a prominent part in the treatment of the disease.

By these and kindred measures the severer aspects of a terrible affliction may often be reduced to a minimum of intensity.

130 EAST THIRTY-SIXTH STREET.

HÆMORRHAGE FROM A CIRCUMTONSILLAR ABSCESS.*

BY WALTER F. CHAPPELL, M. D., M. R. C. S., Eng.,
NEW YORK.

PRIMARY or secondary hæmorrhage from a tonsillar abscess occurs so rarely that the following case seems worthy of our attention:

T. O'B., aged twenty-seven years, a porter by occupation, had had two attacks of quinsy in the past two years, each resulting in an abscess, which had to be opened. The present attack began about December 1, 1899, with great pain on the right side of the throat, extending down the neck. The left side was also swollen and slightly painful. He remained under his family physician's care for five weeks, during which time four incisions were made, with little relief.

He came under my care at the Manhattan Eye, Ear, and Throat Hospital on January 15th, presenting the well-known appearance of patients with quinsy. An examination showed intense swelling of the tissues, internally and externally, and an abscess pointing in the middle of the posterior pillar of the soft palate. A small

*Read before the American Laryngological Association at its Twenty-second Annual Congress.

longitudinal incision was made at this point and about half an ounce of foul pus escaped.

He remained in the hospital, some pus continued to discharge from the opening, the swelling diminished, and his condition improved daily. Early on the morning of January 21st, four days after the abscess was incised, he complained of a sudden severe pain in the throat, followed in a few minutes by a hæmorrhage of about six ounces, which ceased on the application of tannic acid. Four hours later a second hæmorrhage occurred of about eight ounces, which was also stopped by an astringent gargle. An examination of the urine was made at this time, which showed the presence of albumin in large quantities, also epithelial and pus cells, and granular casts with pus corpuscles adherent. The local condition of the throat again improved, without further bleeding until January 26th, when the third hæmorrhage occurred. This partially ceased after about eight ounces of blood had been lost, but more or less oozing continued during the morning. I saw the patient in the afternoon, and found the tonsillar and cervical tissues much distended and painful; some blood still oozed from the opening in the posterior pillar and the abscess cavity was filled with blood clots. A large incision was made through the anterior surface of the soft palate and carried backward until the abscess cavity was reached. After thorough washing out of the blood clots with hydrogen peroxide, the ascending pharyngeal artery was seen at the outer and back wall of the cavity. No ulcerations could be discovered in the walls of the artery, but, naturally, little effort was made in that direction. The cavity was packed with iodoform gauze and the patient returned to bed. The packing was changed daily for ten days, when the wound had healed and no further hæmorrhage occurred.

On the 28th of January a very interesting attack of rheumatism occurred, accompanied by severe pains in the muscles of the calves, and also the abdomen, and some slight joint symptoms. No cardiac implication could be discovered. I might also add that the kidney affection continues at the present time, and there seems to be no doubt that the tonsillar abscess was responsible for the nephritis, as well as the rheumatism.

An examination of the literature of this subject gives reports on ten cases, with two recoveries. The first case occurred in the practice of Dr. Samuel Walker, in 1825. The patient had a double tonsillar abscess. The left one opened spontaneously. On the right side a tumor pointed in front of the thyroid cartilage, and, on being opened, it was found to communicate with a right tonsillar abscess. Two days later the patient died from a great hæmorrhage, the blood gushing from the mouth and nose.

The second case was reported by Dr. Thomas Watson in 1828. Two days after the tonsillar abscess was opened, twelve or fourteen ounces of blood suddenly gushed from the throat and nose, and the hæmorrhage recurred in the evening of the same day, and also on the following morning. The patient then improved for two weeks, when, after he had eaten some meat, the bleeding returned, and while preparations were being made to tie the carotid he died suddenly from suffocation. An autopsy revealed the trachea and bronchi full of blood clots and a large erosion of the lingual artery.

The third case, reported by Dr. Luke in 1829, was a tonsillar abscess, which broke spontaneously and was followed at once by a discharge of about six ounces of blood. Three days later the patient bled again, and in two days had another recurrence, during which it was said he lost pints of blood. The following day he had a fourth attack, when the carotid was tied with success.

The fourth case was reported by Dr. Reeves. The quinsy had opened spontaneously, and hæmorrhage took place the same day, and recurred six or eight times before a physician was consulted. Ligature of the carotid was recommended and declined, the patient dying from several further hæmorrhages.

Dun's case was that of a child, three and a half years of age, suffering from a circumtonsillar abscess, which opened spontaneously. Twenty-four hours later bleeding began from the posterior pillar of the soft palate. Later a blood tumor appeared in the neck. The carotid was tied with success.

Norton's case was that of a child, four years of age, which terminated fatally. An autopsy showed ulceration of the internal carotid.

In Clayton's case, the tonsillar abscess opened spontaneously, and this was followed in some hours by a hæmorrhage which resulted fatally. The internal carotid was found severely ulcerated at the autopsy.

In Grisolle's case the abscess had opened spontaneously and resulted fatally from hæmorrhage. The internal carotid was implicated in a large ulcerating surface.

In Müller's case the abscess had opened spontaneously and several hæmorrhages had occurred, which eventually resulted fatally, and ulceration of the carotid was found at the autopsy.

Brewer's case was seemingly in a healthy man who had an ordinary sore throat. He had several hæmorrhages, which seemed to come from the rupture of a small abscess on the posterior surface of the soft palate.

Remarks.—The spontaneous rupture of the tonsillar abscess in all these hæmorrhage cases is very suggestive, and one cannot but feel that an early incision would have prevented the extensive ulcerations which implicated one of the large vessels. There seems no reason for the great mortality which these reports have shown. Immediate ligation of the carotid, on the occurrence of the first hæmorrhage, should be practised, or, as proved successful in my case, a free incision through the anterior wall of the soft palate and firm packing of the abscess cavity with antiseptic gauze.

The Stylus, a monthly medical journal heretofore edited by Dr. William Porter, of St. Louis, has been purchased by and consolidated with the *Interstate Medical Journal*. Dr. Porter will be associated with Dr. W. B. Outten, Dr. R. B. H. Gradwohl, and Dr. O. F. Ball in the editorial management of the consolidated journals.

Therapeutical Notes.

Enemata of Artificial Serum in the Collapse of Infants.—Rumpelmayer (*Thèse de Paris; Klinisch-therapeutische Wochenschrift*, January 6th) gives the following formula:

- R Sodium chloride. 1 part;
- Sodium sulphate. 2 parts;
- Distilled water. 200 “

M. From one to three drachms to be injected once or twice a day, and caused to be retained by digital pressure on the anus. If an evacuation occurs, the enema is to be repeated.

Naphthalan in the Treatment of Hæmorrhoids.—Rauch (*Deutsche medicinische Wochenschrift*, 1900, No. 39; *Centralblatt für Chirurgie*, January 12th) has seen the use of twenty-per-cent. suppositories of naphthalan followed in ten cases by prompt diminution of the size of the piles, as a result of enduring contraction of the blood-vessels, mitigation of the pain, and the healing of excoriations and rhagades.

A Hæmostatic Pill.—Huchard (cited in the *Klinisch-therapeutische Wochenschrift* for January 6th) recommends the following formula:

- R Quinine sulphate. 90 grains;
- Extract of ergot. 30 “
- Powdered digitalis, } each. . . . 6 “
- Extract of hyoscyamus, }

M. Divide into forty pills.
S. Six to ten pills daily for two or three days.

For Typhoid Fever.—Dr. William Ewart (*Lancet*, December 8, 1900; *Merck's Archives*, January) highly recommends the following:

- R Solution of bichloride of mercury (B. P.). 20 minims;
- Tincture of perchloride of iron, from 15 to 20 minims;
- Syrup of orange or lemon. 1 drachm;
- Water. 1 ounce.

M. This dose is to be administered every six hours throughout the attack, and for ten days after defervescence to guard against a relapse.

The liquor hydrargyri perchloridi of the British *Pharmacopœia* contains one grain of the salt in two ounces of water. Twenty minims, therefore, equals $\frac{1}{48}$ th of a grain of the drug.

For Dysentery.—Hospital Assistant Zahur Pir, C. M. S. (*Indian Lancet*, January 21st), recommends highly the following treatment for dysentery, as having proved of the greatest value when a good deal of trouble through griping pains and frequent stools with mucus and blood were present:

- R Turpentine. 10 minims;
- Tincture of opium. 10 “
- Powdered acacia. 1 drachm;
- White sugar. 1 “
- Peppermint water. 1 ounce.

To be taken three times daily for three days only, after cleansing the intestines with a dose of castor oil. At the expiration of this time:

- R Powdered ipecacuanha. 10 grains.

To be taken thrice daily, half an hour after the following draught:

- R Tincture of opium. 10 minims;
- Compound tincture of cardamoms (B. P.). $\frac{1}{2}$ an ounce;
- Water. 1 ounce.

M.

Apply a sinapism over the pit of the stomach in order to prevent vomiting, which often attends the administration of ipecacuanha in large doses.

For Painful Menstruation.—The *Canadian Practitioner and Review* for February gives the following:

- R Acetanilid. 3 grains;
- Citrate of caffeine. $\frac{1}{2}$ a grain;
- Bicarbonate of sodium. 3 grains.

M. To be taken at one dose, and repeated in one hour if necessary.

Methylene-blue in Hysteria.—Aposti (*Rivista critica di clinica medica*, November 24, 1900; *British Medical Journal*, February 16th) has administered pills of methylene-blue (the dose is not stated) in several cases of hysteria, and states that the morbid symptoms ceased as soon as the blue began to show in the urine. Suggestion is credited with some of the effect. Marimo has had identical results, and considers the antiseptic effect upon self-intoxication from the digestive system as a partial cause of the good effect.

Local Applications for Whooping Cough.—Dr. Guida (*Journal de médecine interne*, January 15th) advises carbolic applications to the pharynx to be made during the access. He uses:

- R Crystallized carbolic acid. 15 grains;
- Glycerin. 180 minims;
- Solution of cocaine hydrochloride, 2 per cent. 75 “

Hydrochloride of Apocodeine in Constipation.—M. Raviart and M. Bertin (*Echo médicale du nord; Journal des praticiens*, January 26th) have found apocodeine, when pure and free from apomorphine, to be a sedative and hypnotic possessing no noxious action on the organism, and increasing the peristaltic action and glandular secretion of the digestive tract. They laud, in habitual constipation, hypodermatic injections into the muscular tissues of thirty minims of the following solution:

- R Hydrochloride of apocodeine. . . 7 $\frac{1}{2}$ grains;
- Sterilized water. 750 minims.

M. The injection may be repeated on several successive days.

For Cystitis.—M. Bazx (*Journal des praticiens*, January 26th) recommends the employment of sodium benzoate in conjunction with turpentine and tar, as follows:

- R Benzoate of sodium, } of each. . 1 $\frac{1}{2}$ grains;
- Pure gum turpentine, }
- Norway tar, }

M. For one pill. From six to eight may be taken daily. At meals tar may also be given, and buchu tea, or tea of uva ursi.

THE NEW YORK MEDICAL JOURNAL,
62-68 West Broadway.

NEW YORK, SATURDAY, MARCH 2, 1901.

THE MUNICIPAL HOSPITALS OF NEW YORK.

WHEN, some months ago, a premature and incomplete account had reached us of the changes in the management of Bellevue and the other municipal hospitals of New York proposed by the charter revision commission, we were doubtful as to the utility of what was then understood to be the chief purport of the changes, and we expressed the doubt in our issue for November 24th. There had then come to our knowledge nothing calculated to correct the natural impression that, in substituting for the present commission a board of trustees to be appointed by the mayor, the revision contemplated such a board as that which exists in Philadelphia, all of whose members are appointed at once or individual members as vacancies arise, and all to hold office for a definite term of years, only the members appointed to fill vacancies holding over. This system would work a useless and even injurious division of responsibility, and would not take the institutions "out of politics."

It subsequently appeared, however, that the commission's recommendation was for a board constituted on the general plan of the boards governing the municipal hospitals of Boston and Cincinnati, the only American cities that we know of in which the public hospitals are what they ought to be. The *personnel* of these boards does not change suddenly, but interstitially, so to speak, one or more members retiring from office at a stated time, so that the methods of hospital management that have been settled upon as the result of experience are not rudely overturned by a new board, and the board in perpetuity—for it often happens that a retiring member is at once reappointed—has a responsibility quite as definite and a policy quite as continuous and undisturbed as one man could have, and even more, for the one man must eventually die or resign or become super-

annuated, and then an untried successor, ignorant of the traditions of the office, would necessarily be called upon to manage affairs of which he knew little or nothing. A board that is practically self-perpetuating is, therefore, more individual in a long term of years than a single person. Moreover, the board of seven trustees proposed by the charter revision commission would in all probability be appointed by the mayor from nominees presented by the New York Association for Improving the Condition of the Poor, the Particular Council of New York of the Society of St. Vincent de Paul in New York, and the United Hebrew Charities of the City of New York. At least, it is provided that the mayor shall call upon these organizations for twice as many nominations as there are trustees to be appointed. He is not bound to appoint any one of the nominees, for it is unconstitutional to limit his appointing power; it is inconceivable, however, that he should ignore the nominations of such important and trustworthy bodies in appointing men to offices wholly destitute of emolument.

The trustee system has worked well for many years in Boston and in Cincinnati. The Boston City Hospital ranks with the best hospitals of the world, public or private. A gold medal was awarded to it for its exhibit at the recent Paris Exposition, where it was rated with the Massachusetts General Hospital, of Boston; the Presbyterian Hospital and the Mount Sinai Hospital, of New York; and the Johns Hopkins Hospital, of Baltimore. The Cincinnati City Hospital has been managed with economy and efficiency, and has thus far been practically undisturbed by the politicians. According to all we have been able to learn, the municipal hospitals of other large American cities, certainly those of Philadelphia (where a quick-transformation board travesties the permanent-board idea), Chicago, St. Louis, and San Francisco, as well as our own, are more or less dominated by petty politics, and it is a matter of common knowledge that they are not creditable to our civilization. There seems now to be a chance to redeem Bellevue and the other municipal hospitals of New York by the enactment of the charter revision commission's recommendations, and we hope to see the redemption accomplished.

THE PLAGUE IN SAN FRANCISCO.

WE have never feared that the few cases of bubonic plague which have occurred in San Francisco would give rise to an epidemic, for we have felt confident that Dr.

Kinyoun, of the Marine-Hospital Service, the Federal quarantine officer there, was the best man that could have been chosen to detect the existence of the disease in case it occurred and to check its spread. Dr. Kinyoun's course for both these purposes has been such as to win for him the admiration of all well-informed persons, and we believe that it will be upheld in spite of the nonsensical and disgraceful denial by the governor of the State that there has been any plague in California, and in spite of the State Senate's bold demand that Dr. Kinyoun be removed from his post. The governor, in a recent message to the legislature, intimates that certain physicians having cultures of plague bacilli in their possession have, "innocently or otherwise"—that is, ignorantly or criminally—inoculated the dead body of some Chinaman with them, and that the finding of the germs in such dead body has resulted in spreading a false alarm calculated to strengthen Dr. Kinyoun's hands and to induce the city of San Francisco to appropriate more money for its board of health. A more preposterous insinuation, a greater insult to an accomplished, experienced, and high-minded sanitarian was never put forth in an official document. The facts of the case are ably stated in the February number of the *Occidental Medical Times*, which has the support of the *Sacramento Evening Bee*.

We do not believe that the people of California are so blind to their own real interests and to their good name as to approve of the State government's course in this matter. Nevertheless, that government must be dealt with by the Marine-Hospital Service. We have no doubt as to the result. An investigation is being carried on by Dr. Simon Flexner, Dr. F. A. Novy, and Dr. Lewellys F. Barker, all men of renown in science and of unimpeachable integrity, and the people may confidently depend on their report to bring the government of California to its senses. Meantime, San Francisco is suffering from a natural distrust which has led to quarantine declarations outside of the State, but, as the *Occidental Medical Times* well says, "if the governor would quarantine infected houses, acknowledge the truth, Colorado, Louisiana, Texas, British Columbia, Mexico, the Hawaiian Islands, etc., would not do in their own behalf what is plainly the duty of the governor of the State of California." No good has ever yet come of denying the existence of infectious diseases which really existed, and we are confident that the people of California will not long tolerate such an ostrich-like policy as the governor and the legislature of their State are now displaying.

THE REPORT OF THE BRITISH MEDICAL ASSOCIATION'S ANÆSTHETICS COMMITTEE.

A COMMITTEE appointed by the British Medical Association in 1891 to investigate anew the subject of anæsthetics presented its report last summer. The report, as now printed, makes a quarto pamphlet of 134 pages. For a copy of it we are indebted to the association's general secretary, Mr. Francis Fowke. The committee delegated its work to an analysis subcommittee consisting of Mr. Hutchinson, Dr. Childs, Dr. Dudley Buxton, Mr. G. Eastes, Dr. Hewitt, and Mr. Rowell. Principally from the hospitals of Great Britain, but to some extent from private practice, the subcommittee obtained a large number of data concerning cases of anæsthetization, which, in their analysis, they classified into "uncomplicated cases," in which, so far as the effects of the anæsthetic were concerned, nothing unusual occurred; "complicated cases," in which there were unusual symptoms or sequelæ referable wholly or in part to the anæsthetic; "cases with minor complications," showing some noteworthy departure from the usual phenomena, but not giving rise to actual anxiety or danger; "cases of anxiety," with symptoms due wholly or in part to the anæsthetic and requiring the adoption of remedial measures, but not involving immediate danger; "cases of danger," with effects due partially or entirely to the anæsthetic and threatening the patient's life; and "cases of death" due wholly or in part to the anæsthetic. The anæsthetic substances employed, including mixtures and sequences of substances, were forty-five in number. In all, there were 25,896 cases analyzed, including 13,393 in which chloroform was used, and 4,595 of ether anæsthesia. This disproportion shows the extent to which chloroform is still employed in the United Kingdom, in spite of repeated demonstrations of its comparatively dangerous nature, demonstrations that are emphasized in the report now under consideration.

The data relate only to general anæsthetics. They have been analyzed from various points of view, and the report, which is largely tabular, shows abundant evidence of arduous and painstaking work on the part of the subcommittee. At present we can deal with it only in so far as it relates to fatal cases, and, even at that, we must limit ourselves to the deaths from chloroform and those from ether. There were eighteen deaths under chloroform anæsthesia, of which three are considered to have been due entirely to the anæsthetic, and four to the anæsthetic principally and to the patient's condition secondarily, while in the eleven others either there was

doubt as to the relative shares taken by the three elements, the anæsthetic, the patient's condition, and the operation, or death was distinctly due to one or both of the two other causes rather than to the anæsthetic. Of the deaths under ether anæsthesia, which appear to have been three in number, not one was held to be due entirely to the anæsthetic. Grouping the fatal and the dangerous cases together, the subcommittee find that with chloroform there is a danger rate of 0.582 per cent., and with ether one of 0.065 per cent. Taken as a whole, the report bears out the opinion, which is growing to be a more and more widely disseminated conviction, that, of the two general anæsthetics most commonly employed, chloroform is far the more dangerous.

A DOCTOR AS A MAJOR-GENERAL.

THE *Philadelphia Medical Journal* for February 23d comments on the deserved promotion, of which we of the medical fraternity may well be proud, of Dr. Leonard Wood, formerly an assistant surgeon in the United States army, to the substantive rank of major-general. But the *Philadelphia Medical Journal*, proceeds to relate that his appointment is regarded in army circles as "practically an appointment from civil life to high rank in the regular army"; and further states that "because the appointment is in the line and not in the medical staff" "it is unprecedented, so far as we can recall, in this country or in any other; in fact, in any other country than this such a promotion would, we suppose, be practically impossible." If this is meant to refer to the leap in rank from that of captain—Dr. Wood's army medical rank—to that of major-general, it may be correct, though, even in this event, it must be remembered that General Wood had passed through the intermediate grades in the volunteer forces engaged in active service; but the transfer from one branch of the service to another—and specifically from the medical branch—has, as we have mentioned on more than one occasion, occurred in both England and France. In the Crimea more than one medical officer was transferred to "combatant" rank, and even rose to command a regiment. So late as in the eighties a veterinary officer in an English hussar regiment was transferred to his corresponding rank of captain in the line during the progress of a campaign in Egypt; while General J. Frédéric Canonge, who in 1899 commanded the Fifteenth French Army Corps, was, as we stated in our issue for February 18th of that year, another medical man exercising high "combatant" command.

So the case of General Leonard Wood, M. D., though conferring additional lustre on the ranks of physicians who have attained high "combatant" rank, is by no means unique.

THE AMERICAN HUMANE ASSOCIATION'S ANTI-VIVISECTION PAMPHLET.

DR. W. W. KEEN, of Philadelphia, has been good enough to furnish us with a copy of certain recent correspondence between himself and the president of the American Humane Association, Mr. James M. Brown, concerning Dr. Keen's statement, made at a Senate committee hearing, held about a year ago, on Senator Gallinger's antivivisection bill, to the effect that many of the reports of alleged instances of cruel experimentation on human beings referred to in the association's pamphlet were so vague and indefinite that he had been unable to look them up, and some of them garbled and inaccurate. All this Mr. Brown denies, and he challenges Dr. Keen to show grounds for his criticism. In his reply, dated January 21, 1901, Dr. Keen demonstrates with regard to case after case the utter inadequacy of the reference to authority, and in a number of cases such garbling of the original reports as clearly shows intentional misrepresentation. We hope the correspondence will be as freely circulated as the pamphlet was. It will, of course, have no effect on the antivivisectionists themselves, but to the mind of any mature, intelligent, and fair-minded human being it must show the straits to which the American Humane Association is reduced for alleged facts with which to bolster up its accusations.

HEAT AS A TEST OF THE PRESENCE OF PUS.

IF certain observations of Lewin's (*Semaine médicale*, 1901, No. 3; *Wiener medicinische Blätter*, January 31st) are corroborated, we shall have a simple means often available for the detection of the presence of pus. In cases of inflammation of the knee joint he has observed alleviation of the pain consequent upon warm applications; if pus was present, however, the pain was aggravated. His observation has been to the same purport also in cases of inflammation of the vermiform appendix.

THE FORMATION OF GAS IN THE LIVER.

A MORBID phenomenon not before recorded seems to have been observed by Kerchensteiner, of Munich (*Deutsches Archiv für klinische Medizin*, lxi, 1; *Wiener medicinische Blätter*, January 31st), namely, the formation of gas in the liver during life (in the death struggle), due, he thinks, to colon bacteria finding their way into the organ and multiplying at the periphery of the acini so as to interfere with the capillary circulation and then giving off gaseous products.

SYPHILIS AGGRAVATED BY SMALL-POX.

THE profound impression often made on the system by small-pox, even in its modified form, was well illustrated at a recent meeting of the French Society of Dermatology and Syphilography (*Annales de dermatologie*

et de syphiligraphie, January) by M. Du Castel, who showed a young girl who had had syphilis of medium intensity for a year and a half when she was attacked with mild varioloid. Nothing special occurred during the attack, but with her convalescence the syphilis took on a grave form; she became covered with a crustaceous eruption and with ulcerations, particularly on the lower limbs.

FRACTURE OF THE LARYNX AS A CAUSE OF SUDDEN DEATH.

L. STEPHENS (*Guy's Hospital Reports*, liv, 1900; *Centralblatt für Chirurgie*, February 9th) reports the case of a man who received a blow on the larynx and fell down dead. At the *post-mortem* examination no other injury or abnormality was found anywhere in the body than a fracture of the right greater cornu of the hyoid bone and one of the left wing of the thyroid cartilage. He asks why the man died, and if sudden death can result from a fracture of the larynx. R. von Hippel, who abstracts the report for the *Centralblatt*, says that the latter question must be answered in the affirmative, and adds that death may take place from suffocation. We may suggest that the mode of infliction of the injury, whether by constriction or by a blow, may have a bearing upon the result and upon the mechanism of its occurrence. In the case of a blow, it is conceivable, it seems to us, that rapidly fatal shock may follow the concussion of the great nerves of the neck that may be a concomitant result of the violence.

ANOTHER MEDICAL V. C.

ACCORDING to the *British Medical Journal* for February 16th, yet another Victoria Cross for conspicuous bravery on the field of battle has been awarded to an army medical officer. Lieutenant W. H. S. Nickerson, of the Royal Army Medical Corps, is the recipient on this occasion. The unusually large proportion of these rewards "for valor" which have been awarded to members of the medical branch of the British service must be a source of gratification to the medical profession all the world over; and there is no room for doubt that, even in countries where no such certifying hall mark exists, there is as great a proportion of sterling mettle" in the medical members of the army as in Great Britain.

TETANY ATTRIBUTED TO GASTRIC DILATATION.

GRUSINOW, of Moscow (*Klinitscheski Journal*, 1900, No. 2; *Berliner klinische Wochenschrift*, November 2th), relates the history of a case of tetany apparently due to enormous dilatation of the stomach, which reached quite to the pubic symphysis. Improvement followed drainage of the stomach and the use of appropriate diet, and a cure was effected by gastro-enterostomy. Gastrectomy may, we presume, be counted as among the rarer causes of tetany.

News Items.

Society Meetings for the Coming Week:

MONDAY, March 4th: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association (annual); Hartford, Connecticut, Medical Society; South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society.

TUESDAY, March 5th: New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Herkimer (annual, Herkimer), N. Y.; Essex, Massachusetts, South District Medical Society (annual, Salem); Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Maine, County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, March 6th: New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (New Brighton), N. Y.; Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, March 7th: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, March 8th: Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, March 9th: Obstetrical Society of Boston (private).

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending February 23, 1901:

DISEASES.	Week end'g Feb. 16.		Week end'g Feb. 23.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	20	11	28	5
Scarlet Fever.....	404	24	437	24
Cerebro-spinal meningitis.	0	0	0	0
Measles.....	159	7	198	5
Diphtheria and croup.....	296	50	257	37
Small-pox.....	25	6	46	9
Tuberculosis.....	280	189	250	179

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from February 9 to February 23, 1901:

ASHFORD, BAILEY K., First Lieutenant and Assistant Surgeon, will accompany a detachment of recruits from Fort Slocum, N. Y., to San Francisco.

BACHE, DALLAS, Colonel and Assistant Surgeon-General, is granted leave of absence for three months, on account of sickness.

BOYER, ARTHUR L., Acting Assistant Surgeon, is granted leave of absence for one month. During his absence Acting Assistant Surgeon HARRY D. BELT will, in addition to his present duties, attend the sick at Fort Terry and Fort Michie, N. Y.

CHAMBERLAIN, WESTON P., First Lieutenant and Assistant Surgeon. Upon his return to Fort Adams, after leave of absence, Acting Assistant Surgeon ADRIAN D. WILLIAMS will proceed to Fort Greble for temporary duty.

KENDALL, WILLIAM P., Major and Surgeon, will proceed to Fort Slocum, N. Y., to relieve CHARLES M. GANDY, Captain and Assistant Surgeon, who will proceed to San Francisco for transportation to Manila.

PENROSE, GEORGE H., Major and Surgeon, will report to the commanding general, Department of California, for temporary duty.

REED, WALTER, Major and Surgeon, is detailed as a member of the board of medical officers appointed to meet in Washington for the examination of candidates for admission to the Medical Corps of the Army.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending February 23, 1901:

HOLCOMBE, R. C., Assistant Surgeon. Detached from the *Glacier* and ordered to duty with a detachment of marines in Pollok, Philippine Islands.

ROSS, J. W., Surgeon, retired. Ordered to report to the chief sanitary officer of the city of Havana for duty. Special order of the Department of Cuba, February 15th.

Marine-Hospital Service Health Reports:

The following cases of small-pox, cholera, and plague were reported to the surgeon-general during the week ending February 23, 1901:

<i>Smallpox—United States.</i>			
Los Angeles, California.....	Feb. 2-9.....	1 case.	
San Francisco, California.....	Feb. 2-9.....	7 cases.	
Jacksonville, Florida.....	Feb. 9-16.....	5 cases.	
Chicago, Illinois.....	Feb. 9-16.....	14 cases.	
Wichita, Kansas.....	Feb. 9-16.....	9 cases.	
New Orleans, Louisiana.....	Feb. 9-16.....	4 cases.	4 deaths.
Manistee, Michigan.....	Feb. 9-16.....	3 cases.	
St. Paul, Minnesota.....	Jan. 26-Feb. 9..	8 cases.	
Manchester, New Hampshire...	Feb. 9-16.....	1 case.	
New York City, New York.....	Feb. 9-16.....	25 cases.	6 deaths.
Ashtabula, Ohio.....	Feb. 9-16.....	3 cases.	
Cleveland, Ohio.....	Feb. 9-16.....	48 cases.	
Youngstown, Ohio.....	Feb. 9-16.....	1 case.	
Allegheny City, Pennsylvania...	Feb. 9-16.....	3 cases.	
Erie, Pennsylvania.....	Feb. 9-16.....	1 case.	
Greenville, South Carolina.....	Feb. 9-16.....	1 case.	
Memphis, Tennessee.....	Feb. 9-16.....	19 cases.	1 death.
Nashville, Tennessee.....	Feb. 9-16.....	9 cases.	
Green Bay, Wisconsin.....	Feb. 10-17.....	1 case.	
Milwaukee, Wisconsin.....	Feb. 8-16.....	1 case.	

<i>Smallpox—Foreign.</i>			
Antwerp, Belgium.....	Jan. 19-26.....		1 death.
Bradford, Great Britain.....	Jan. 6-13.....	15 cases.	2 deaths.
Naples, Italy.....	Jan. 20-30.....	26 cases.	2 deaths.
Officially reported.			
City of Mexico, Mexico.....	Jan. 27-Feb. 3..		1 death.
St. Petersburg, Russia.....	Jan. 19-26.....	8 cases.	1 death.
Odessa, Russia.....	Jan. 19-26.....	13 cases.	8 deaths.
Glasgow, Scotland.....	Jan. 25-Feb. 8..		34 deaths.
Singapore, Straits Settlements.	Dec. 22-29.....		1 death.

<i>Yellow Fever.</i>			
Havana, Cuba.....	Feb. 2-9.....	3 cases.	1 death.

<i>Plague.</i>			
Hong Kong, China.....	Jan. 5-12.....		2 deaths.
Tainan, Formosa, Japan.....	Jan. 1-16.....	28 cases.	22 deaths.

<i>Cholera.</i>			
Singapore, Straits Settlements.	Dec. 22-29.....		16 deaths.

A Doctor Fined for Issuing a False Death Certificate.
—A Brooklyn physician has been fined \$100 for filing a false certificate of death in a case of small-pox.

Changes of Address.—Dr. J. F. Chmelieck-Luhan, to No. 318 East Seventh-ninth Street, New York; Dr. J. E. Dearden, to No. 1368 Lexington Avenue, New York.

A Medical Union in Jamaica, L. I., is about to be formed, with a view to protecting physicians against imposition by persons who systematically refuse to pay their bills.

Dr. Paul M. Mecray, surgeon at the Cooper Hospital, Philadelphia, has been appointed surgeon and physician to the Pennsylvania Railroad Company, to succeed Dr. Dowling Benjamin.

A Site for the Oakland Medical College has been selected at Thirty-first and Grove streets, Oakland, Cal. measuring 80x115 feet. Architects are at work preparing plans for the erection of a substantial modern structure.

County Medical Society Committee on the Social Evil.—At the meeting of the New York County Medical Society, held on February 26th, the president was authorized to appoint a committee of seven to investigate the social evil in this city.

New York City's New President of the Board of Health.—The appointment by Mayor Van Wyck of Colonel M. C. Murphy to the head of the police force of Greater New York made vacant the office of president of the health board, and to that position former Police Commissioner Sexton was appointed.

Dr. Daniel Lewis Appointed State Health Commissioner.—Dr. Daniel Lewis, of New York city, who has served on the New York State board of health since 1895, having been its president for three terms, has been appointed State health commissioner by Governor Odell under the recently enacted law which substituted a single-headed commission for the State board of health. His salary will be \$3,500 annually.

Sand Filtration for Washington Water Supply.—The Senate Committee of the District of Columbia has recommended the adoption of a system of filtration through sand, supplemented by a series of sedimentation basins in which, during periods of excessive turbidity of the water, the use of coagulants can be carried on. It is estimated that this latter step will be necessary about one eighth of the time.

Medical Legislation in Colorado.—The Colorado Medical Liberty League, the Colorado Antivaccination Society, and the Spiritual Truth Society have instituted an active campaign against the passage of any bill regulating the practice of medicine in the State by law. Such bills have been introduced into both the Senate and the House, but it seems probable, from the tone of the newspaper reports, that the efforts to prevent the passage of any medical legislation will prove effectual.

A Medical Practice Law for California.—A bill regulating the practice of medicine in California has been passed by the legislature, after being so amended as to be no longer obnoxious to the Christian Scientists and osteopaths. The act provides for the creation of a board of medical examiners to be appointed by the medical societies of the allopathic, homœopathic, and eclectic schools. The provisions regarding the qualifications of practitioners are more strict than heretofore power is given to revoke licenses for unprofessional conduct, and advertising improbable or excessive claims to curative powers is ground for the charge of unprofessionalism.

First Aid to the Injured.—The annual meeting of the Society for Instruction in First Aid to the Injured was held recently in New York city. The annual report, which was read by President Charles H. Marshall showed that over 13,000 persons had been instructed by the society since its beginning. Word was received from Fire Chief Croker that he hoped his men would have the usual instruction this year. President William H. Bald-

in, Jr., of the Long Island Railroad, wrote that the instruction given to the employees of the road last year was very beneficial.

Free Clinical Lectures on Syphilis.—A series of nine clinical lectures on syphilis by the members of the visiting and consulting staffs of the New York Skin and Cancer Hospital, will be given at the hospital on Wednesday afternoons at 4:15 o'clock, beginning on March 6th. The lectures are free to members of the medical profession on presentation of their professional cards. The lecturers include Dr. A. Jacobi, Dr. L. Duncan Bulkley, Dr. D. Bryson Delavan, Dr. David Webster, Dr. Edward Janeway, Dr. Edward D. Fisher, and Dr. Willy Meyer.

An Assistant Surgeon of the Russian Navy Charged with Desertion.—Leo Alexandroff, an assistant surgeon of the Russian cruiser *Variag*, who was arrested as a deserter, was set free on July 23, 1900, by a decision of the United States Court of Appeals. Alexandroff came to this country with a crew intended for the *Variag* while the vessel was building at Cramps' shipyards. Shortly after his arrival he took out his first naturalization papers, and was later arrested as a deserter. The surgeon claimed that, as the *Variag* was not in commission, he could not desert from a ship that did not exist. It is probable the case will be taken to the United States Supreme Court.

Plague Quarantine in Louisiana.—Declaration of the existence of bubonic plague at Cape Town has caused the officers of the Louisiana State board of health to renew their stringent measures of quarantine, due directly to the fact that New Orleans is the shipping port of horses and mules bought by the British government for the army in South Africa. The Louisiana State board of health will require special quarantine observances. Ships will be detained five days, and, to prevent the landing of rats, vessels are required to provide their awnings with metal discs, and funnels opening toward the ship, the funnels to be twenty inches in diameter, with sharp serrated edges. At sunset vessels must withdraw one hundred feet to an anchorage.

The Brooklyn Water Supply.—The committee on public health of the Kings County Medical Association submitted a report to the association upon the Brooklyn, N. Y., water supply, which, after rehearsing the facts ascertained regarding the water supply, concluded with the following resolutions, which were adopted by the association:

Resolved, That this society recognizes that certain sources of the water supply of the Borough of Brooklyn are a menace to the public health;

Resolved, That this society urges upon the department of health, and the department of water supply, the necessity of the sanitary patrol of the whole watershed, as provided for by the charter of the city;

Resolved, That it is the sense of this society that the early construction of a sand filtration plant for the filtration of all our supply is necessary for the protection of the public health.

Mark Twain Defends Osteopaths.—Mark Twain appeared before the committee on public health of the Assembly of the State of New York on February 28th in behalf of a measure introduced by Mr. Seymour designed to license osteopaths. Mr. Clemens did not propose to know anything more about osteopathy than that

he had been treated by an osteopath in Europe and been benefited by the treatment. His interest, he said, was in the preservation of personal liberty. He said that as we had full liberty of choice in selecting spiritual advisers, we should have the same liberty as regards advice regarding the care of our bodies. A large delegation from the New York County Medical Society appeared in opposition to the bill. Speeches in opposition to the measure were made by Dr. Elliot Harris, Dr. Floyd Crandall, Dr. Frank Van Fleet, Dr. Charles N. Dowd, Dr. Henry D. Didama, regent of the Medical University of Syracuse, and Jacob Bolin, the president of the New York Society of Masseurs.

A Meeting of the Legislative Committee of the American Medical Association was held in Washington recently. Among the matters discussed was the army reorganization bill, which the committee denounced as unfair in its dealings with the medical men of the army. Objection was also made to the codification of the postal laws, or rather to that section which affects weekly publications, the medical journals being included. This law, it was declared, will increase the expenses of the journal many thousands of dollars a year. The meeting was largely attended and the results very satisfactory to all concerned. Decided action was taken in opposition to the army reorganization and to section 18 of the codification of the postal laws. It was also determined to urge the passage of the Senate bill now pending in the House relative to the Marine-Hospital Service, and the precautions to be taken in regard to the spread of diseases along the coast. The chairman, Dr. H. L. E. Johnson, was given authority so as to facilitate action on matters affecting the profession.

The Richmond Academy of Medicine and Surgery.—At the last regular meeting, on Monday evening, February 25th, the subject for discussion was a paper by Dr. W. A. Deas entitled *Cyclic Albuminuria*.

The St. Louis Medical Society of Missouri.—At the last meeting, on Saturday, February 23d, Dr. John Young Brown read a paper entitled *Surgical Management of General Peritonitis Resulting from Perforating Appendicitis*.

The New York State Medical Society organized a Chautauqua county branch in Buffalo recently. The following officers were chosen: President, Dr. Thomas D. Strong, of Westfield; first vice-president, Dr. William M. Bemus, of Jamestown; second vice-president, Dr. O. C. Shaw, of Cassadaga; secretary and treasurer, Dr. H. A. Eastman, of Jamestown.

The New York Academy of Medicine.—At the next stated meeting, on Thursday, March 7th, the order for the evening is as follows: Alcohol and Alcoholism, by Professor R. T. Chittenden, of New Haven; and a discussion on Alcohol as a Food—Its Direct Action on the Nerve Cell, its Effects on Americans, and the Aspect of the Law and the Inebriate, by Dr. A. A. Smith, Dr. M. Allen Starr, Dr. H. M. Biggs, Dr. Walter B. James, Dr. James Ewing, Dr. James Collins, and others.

Small-pox.—New cases of small-pox have been reported from several localities in various parts of the United States, but the disease does not appear to be spreading as rapidly as it was some two weeks ago. Isolated cases are reported from several localities in Wisconsin, hitherto not visited by the disease. In

Washington three public schools were temporarily closed on account of the discovery of a case of small-pox in a house inhabited by children attending these schools.—In response to a parliamentary inquiry in the legislature of Ontario, the government stated that in all there had been 118 cases of small-pox in thirty-five districts. In the recent Toronto Junction, Port Arthur, and Sudbury outbreaks there had been forty-four cases, and on each occasion the disease had not been first diagnosed as small-pox, and many people had thus been subjected to infection. The department had required isolation and vaccination in the infected districts, and as a consequence there had been a general vaccination of the school population. In many of the mining, lumber, and railway camps thousands of men had been vaccinated.—In New York city and Brooklyn several new cases have been reported, and the health officials have expressed the fear that owing to the laxness in regard to vaccination the disease will continue to spread.

Vacancies in the House Staff of Mount Sinai Hospital, New York city, will be filled by a competitive examination to be held at the hospital on March 28th and 29th. The appointments are open to graduates in medicine or to those who will graduate before July 1, 1901. Written application should be made to J. Rudisch, M. D., Mount Sinai Hospital, New York city.

Hospital Staff Changes.—Dr. James T. Burdick, of Brooklyn, has been appointed head surgeon at the hospital of the State Soldiers' and Sailors' Home at Bath, N. Y., by the trustees of that institution. The present head surgeon is Dr. Oran W. Smith. The trustees declared that Dr. Smith had resigned. When seen by a newspaper reporter, Dr. Smith said two months ago he handed his resignation to Commandant Davidson, but about two weeks ago withdrew it. He is a veteran, and an appointee of the civil service, and cannot be removed except upon charges. No charges have been made against him.—Dr. Frank H. Glazebrook and Dr. Henry P. Merrill have resigned their positions as house physicians in the Orange Memorial Hospital. The resignations are said to have been due to a disagreement with the superintendent.—Dr. J. Halpenny, one of the resident medical assistants of the general hospital at Winnipeg, Manitoba, has been appointed assistant medical superintendent.

Hospital Buildings and Endowments.—A bill has been introduced into the Michigan legislature to provide Detroit with a free hospital, to cost that city \$100,000.—A site for Mary's Help Hospital, to be established in San Francisco, has been purchased. The hospital will cost \$250,000, which sum was the bequest of the late Mrs. Kate Johnston, and in the institution women and children will be treated free of all cost.—The sum of \$75,000 has been appropriated for an addition to the county hospital at Milwaukee.—The foundation of the big annex to the Home for Incurables at New Orleans has been laid, and the corner-stone will soon be set in place.—Plans for a new hospital for Oakland, Cal., are being considered.—With the condition that the institution is not to be used for contagious or infectious diseases, James E. Martine, of Cedar Brook, N. J., has offered a site for the new Muhlenberg Hospital at Plainsfield, N. J.—Plans have been drawn up for the enlargement of the Chicago Lying-in Hospital and Dispensary.—A bill has been introduced into the Wisconsin legislature to establish a State hospital in

some suitable location for the treatment of incipient pulmonary tuberculosis. The bill makes an appropriation of \$100,000 for the hospital, which is to be called the Wisconsin State Sanatorium, and is placed under the supervision of the State board of control. A site embracing not more than 1,000 acres is to be secured.—Much trouble is being met with in finding a suitable location for the proposed new Civic Hospital at Montreal. The suggestion that meets with most favor is that it be located on St. Helen's Island. The board of aldermen have declined to vote an appropriation for the hospital.—The sum of \$1,000 has been donated to the general hospital endowment fund of Montreal by Mrs. J. B. Boulter.—It is proposed by the Boston board of health to establish a home for incurable consumptives, and the sum of \$400,000 is to be asked for with which to establish it.

Births, Marriages, and Deaths.

Married.

BONNER—BERLINER.—In Brooklyn, on Thursday, February 21st, Dr. Adolph Bonner, of New York, and Miss Rachel Berliner.

LAFERME—HAMMOND.—In Baltimore, on Saturday, February 23d, Mr. Charles Laferme and Dr. Katherine L. Hammond, of Chicago.

ORBISON—GILE.—In Overbrook, Pennsylvania, on Monday, February 25th, Dr. Thomas J. Orbison, of Philadelphia, and Miss Virginia Gile.

POPE—WRIGHTMAN.—In San Francisco, on Tuesday, December 25th, Dr. Saxton Temple Pope, United States Army and Miss Emma Wrightman.

Died.

BATCHELDER.—In Danvers, Massachusetts, on Friday February 15th, Dr. Henry F. Batchelder, in the forty-second year of his age.

BLACK.—In Moberly, Missouri, on Tuesday, February 19th, Dr. W. E. Black, in the fifty-ninth year of his age.

CAMP.—In Great Barrington, Massachusetts, on Sunday February 24th, Dr. Samuel Camp, in the seventy-third year of his age.

FAGIN.—In Santa Cruz, California, on Friday, February 22d, Dr. Pierce B. Fagin, in the eighty-third year of his age.

GIVEN.—In Clifton, Pennsylvania, on Saturday, February 23d, Dr. S. A. Mercer Given, in the forty-first year of his age.

GLEZEN.—In Evansville, Indiana, on Wednesday, February 13th, Dr. Samuel Glezen, aged eighty-two years.

HODGES.—In Chicago, on Monday, February 18th, Dr. Frederick J. Hodges, of Ashland, Wisconsin, in the thirty-seventh year of his age.

HODGMAN.—In New York, on Tuesday, February 26th, Dr. Abbott Hodgman, in the sixty-ninth year of his age.

LINSLEY.—In Burlington, Vermont, on Sunday, February 17th, Dr. J. H. Linsley, in the forty-third year of his age.

MARSH.—In West Point, Mississippi, on Friday, February 15th, Dr. Walworth Marsh, in the twenty-ninth year of his age.

NICHELL.—In Buffalo, on Friday, February 15th, Dr. Henry Nichell, in the eighty-first year of his age.

O'REILLY.—In St. Louis, on Sunday, February 24th, Dr. Thomas O'Reilly, in the seventy-fifth year of his age.

PLEEN.—In Minneapolis, Minnesota, on Thursday, February 21st, Dr. William Pleen.

POTTER.—In Lafargeville, N. Y., on Monday, February 18th, Dr. H. B. Potter, in the sixty-second year of his age.

SEAMAN.—In Brooklyn, on Sunday, February 17th, Dr. Richard S. Seaman, in the seventy-sixth year of his age.

SISTRUNK.—In Society Hill, Alabama, on Monday, February 11th, Dr. John Sistrunk, aged sixty-eight years.

SMITH.—In Colorado Springs, on Wednesday, February 20th, Dr. M. G. Smith, in the eighty-fifth year of his age.

TEDFORD.—In Moberly, Missouri, on Wednesday, February 13th, Dr. J. Tedford, aged seventy-five years.

THOMAS.—In Corry, Pennsylvania, on Tuesday, February 19th, Dr. John M. Thomas, formerly of the United States Army, in the seventy-fifth year of his age.

Pith of Current Literature.

Boston Medical and Surgical Journal, February 21, 1901.

U. S. Army Pathological Laboratories in the Philippine Islands. A Description of the Work of the Army Pathological Laboratories and General Remarks on the Investigation of the Diseases of the Philippines. By Dr. Joseph J. Curry.—The author says a word as to the advantages of laboratories on hospital ships. In smooth water and at anchor, it is possible to do practically the same work as in a laboratory on land, and, in addition to the value of a laboratory for the purpose of establishing diagnoses in cases on shipboard, the hospital ship, moving as it does to the various ports in the islands, can render the service of a portable laboratory to the cities and towns the ship reaches. The author considers the subject of the obscure fevers of the Philippine Islands to be a promising one. Some space is devoted to the difficulties that hamper bacteriological investigation in the tropics, and the author asserts that the bacterial flora of the tropics is apparently as rich and varied as its botanical flora.

Dysenteric Diseases of the Philippine Islands, with Special Reference to the *Amœba Coli* as a Causative Agent in Tropical Dysentery. By Dr. Joseph J. Curry.—The author believes that the *Amœba coli* plays a very important part in the ætiology of tropical dysentery, and he asserts that the finding of the amœba in healthy intestines is no more weighty an argument against it as an ætiological factor than the finding of the Klebs-Löffler bacillus in healthy throats is against that organism being the causative agent of diphtheria. There are, however, two distinct types of dysentery in the Philippines, one amœbic dysentery, and the other an acute dysentery, in a number of cases of which the *Bacillus dysenteriae* of Shiga occurs. There are, in addition, cases of subacute and chronic dysentery, in which neither the *Amœba coli* nor the *Bacillus dysenteriae* is found.

Uterine Fibroids. By Dr. Homer Gage.—The author agrees with the statement of Kelly that no more important advances can be made by the gynæcologist in the immediate future than by extending the indications for myomectomy and narrowing the field of hysteromyomectomy. Myomectomy is contra-indicated in extreme anæmia, when it is desirable to avoid a protracted operation, in the presence of extensive pelvic inflammation, and when the uterus is larger than a six months' pregnancy. With these few plain limitations, myomectomy within the proper age limit must always be the operation of election. The author believes that a steady improvement in technique will still further widen the field for its practice, and will give us, at least in a very large number of cases, a safe, non-mutilating method of dealing with uterine fibroids.

Dysbasia Intermittens Angeiosclerotica (Intermittent Lameness of Vascular Origin). By Dr. James J. Putnam.—Among the diseases which count as very rare, this deserves a prominent place. According to the author, the characteristic intermittence during rest and recurrence during exertion is probably due to the fact that, when the muscles are in use, either an unusual supply of blood is needed or a vascular cramp is induced.

Rupture of the Right Iliac Artery. By Dr. F. C. Shattuck.

Lead Encephalopathy. By Dr. F. C. Shattuck.

Osteo-arthritis. By Dr. F. C. Shattuck.

Friedreich's Ataxia. By Dr. James J. Putnam.

Splenectomy. By Dr. J. C. Warren.

Loose Semilunar Cartilages. By Dr. J. C. Warren.

Plastic Operation for Rodent Ulcer. By Dr. J. C. Warren.—The author presents a case illustrating how this form of cancer may remain localized for great lengths of time; calling attention to the necessity of performing a major operation in many of these cases, and holds out hope for a permanent cure, even in cases which physicians are prone to regard as too far advanced for further treatment.

Philadelphia Medical Journal, February 23, 1901.

The Value of Sputum Examinations to the General Practitioner. By Dr. M. Howard Fussell.—In cities such as Philadelphia and New York, where the board of health attends to the matter free of charge, there is not the slightest excuse for the very busiest man to neglect the precaution of early sputum examinations. Outside of such centres, doctors should familiarize themselves with the necessary procedures; such advice, according to the author, is practical. A working knowledge of the microscope and the ability to recognize various organisms when seen under the microscope, are indispensable, and Austin Flint's statement that "the time will soon come when, in order to corroborate the diagnosis, microscopical examinations of the sputa will be considered as much a matter of course as examinations of urine for evidence of renal disease," should be ever present to all of us.

Resection of the Rectum per Vaginam. By Dr. John B. Murphy.—According to the author, the advantages offered by the vaginal route are: (1) The sacrum and posterior bony wall of the pelvis are not disturbed; (2) the field of operation is as extensive and the anatomical parts as accessible as in the transsacral operations; (3) the peritoneal cavity is opened in both the vaginal and sacral operations, and in neither is it a source of great danger; (4) the diseased tissue is more accessible for inspection, and the extent to which the operation may be carried in an upward direction is as great as, if not greater than, by the sacral route; (5) the peritonæum may be drained freely through the vagina; (6) a perfect end-to-end approximation, either by suture or by the use of the button, may be secured. The preferable method of uniting the two ends is by interrupted suture of silk, because, as there is no peritonæum on the sphincteric segment, failure of union with the button is to be feared; (7) the sphincter is retained and the perineal body is restored. There is diminished action of the levator ani muscle; (8) when the operation is complete, the parts are practically in their normal positions.

Amputation of Both Feet under Spinal Anæsthesia with Cocaine. By Dr. Augustus C. Behle.—The author especially commends this method of inducing anæsthesia to the country practitioner. He asserts that with this procedure the skilled anæsthetist may be dispensed with. In the present instance, fifteen minims of a sterile two-per-cent. solution of cocaine produced an anæsthesia lasting about two hours. No shock followed the operation, and none of the sequelæ, such as nausea, vomiting, and headache, which some surgeons have reported after the use of this method, were observed. The

rise of temperature after the operation was very slight. Recovery was rapid, and the patient was discharged on the fifteenth day after the operation.

Sarcoma of the Ribs. By Dr. C. C. Worden.—The author reports a case and gives a summary of the literature of all the seventy-three cases thus far reported; sixty-five were susceptible of operation. The total mortality was forty-eight per cent. The mortality of the cases susceptible of operation was forty-six per cent. Traumatism is etiologically concerned in twenty-two per cent. The patients in sixty-four per cent. of the cases were males; the youngest was ten years old, the oldest sixty-six.

Congenital Umbilical Hernia; Report of a Case, and Table of Cases Hitherto Reported. By Dr. Homer E. Safford.—A rational treatment of congenital umbilical hernia is, according to the author, based upon two things: aseptic practice in surgery, and a better understanding of embryological development. Intervention should take place as early as possible after birth: waiting endangers the membranes from gangrene and peritonitis; and radical operation is always the most rational if we have the means and assistance at hand.

Medical Record, February 23, 1901.

The Necessity for a More Careful Investigation as to the Cause of Outbreaks of Infectious Diseases. By Dr. Alvah H. Doty.—The conclusion at which the author has arrived, after a number of years' experience, is that the clothing of well persons and the cargoes of ships are rarely the means of transmitting disease, and, though no reasonable precautions to prevent possible danger from this source should be omitted, the author calls attention to the urgent necessity of looking elsewhere for the cause of an outbreak of infectious disease the origin of which is unknown. This cause he believes to be mild ambulant or convalescent cases which pass unrecognized. The author points out that an acceptance of this view certainly does not mean that we should relax our efforts to protect the public health, but tends to bring about a more careful and thorough investigation as to the means of transmission of infection, which, he believes, is imperatively called for.

A Method of Fixation for Loose Kidneys. By Dr. Robert T. Morris.—In the author's opinion, loose kidneys are so common that every general practitioner presumably has a number of patients who are suffering from this cause, and the reason that more cases are not discovered in *post-mortem* examinations is that the kidney promptly assumes its normal position, usually while the patient is in the recumbent posture, and rigor mortis fixes it quite securely in place. Cases for operation, according to the author, are the ones which continue to produce important symptoms after the diagnosis has been well made and abdominal support and general medical treatment have been well tried. The method of examination described by Israel is the one favored by the author. In the operation proposed a flap of capsule, including the larger part of the mesial surface of the kidney, is incised with a scalpel, and the flap of capsule is then stripped up from the parenchyma, but remains attached to the convex border of the kidney. The flap of the capsule is then drawn through a slit in the psoas muscle or in the quadratus muscle, and is there sutured into place. This brings bare parenchyma also into contact with the psoas or quadratus fascia, where it forms a firm connective tissue attachment.

Convulsions with Scarlet Fever, and the Report of a Very Severe Case, with Perfect Recovery, and Important Deductions from the Treatment. By Dr. Herman E. Hayd.—Every case of scarlet fever is a law unto itself; convulsions may occur, and do occur, when least expected, and every case should be closely watched for many weeks. The urine should be frequently tested as to its specific gravity and for albumin, and the urea calculation should be often made. Only the most digestible food should be given, and, if possible, such foods as produce little gastric and intestinal putrefaction. If milk cannot be digested or will not be taken, only water should be given by the mouth and the patient should be nourished by nutrient enemata. Hypodermoclysis is a very valuable and safe method of introducing water into the system, and as much as two or three pints can be used; with proper precautions no danger will result or severe abscess formation follow. Enteroclysis, if much fever is present, should be employed once or twice during twenty-four hours, and a number of quarts, or even gallons, of water may be used at a time. Strychnine and digitalin are our most valuable heart stimulants, and brandy is our best food and diffusible stimulant.

Journal of the American Medical Association, February 23, 1901.

The Bacterial Toxines. By Dr. Victor C. Vaughan and Dr. Thomas B. Cooley.—The colon bacillus in virulent form contains within the cell a toxine which is fatal to guinea-pigs of from two hundred to three hundred grammes weight, in quantities of less than one milligramme. The aqueous extract of the cells of the colon bacillus grown on agar is inert. The entire germ is highly resistant to heat and to dilute acids and alkalies. The cell wall of the colon bacillus is digested by the prolonged action of artificial gastric juice, which does not alter the toxine. The toxine, as thus obtained, is insoluble or but slightly soluble in dilute acid, but is slightly soluble in water, and more readily in dilute alkalies. This toxine responds to the ordinary proteid reactions. The toxine, after being freed from the cell membrane, is not destroyed by being boiled.

The True Rôle of Drugs in the Management of Consumptives. By Dr. Solomon Solis-Cohen.—Bearing in mind the limitations of drugs as well as their powers, and carefully selecting them for definite purposes, they may be made to fulfil a useful, but secondary, part in the treatment of patients having pulmonary tuberculosis.

The Importance of an Early Diagnosis of Tuberculosis. By Dr. A. Mansfield Holmes.—The author believes that the fact should be more generally recognized that, if the vital forces become impaired from any cause whatever, the resistance to the tuberculous infection is diminished and the danger of infection increased. An early diagnosis is of supreme importance, and, if we hope to secure good results, we must resort to means of examination which will enable us to detect the disease before it has become firmly established. Expectoration is frequently present for a considerable time before bacilli can be found, and the diagnostician who waits for the appearance of bacilli in the sputum fails to diagnose the disease in its incipency, and loses the most valuable period for treatment. After carefully considering the previous history, the general appearance of the patient, and the symptoms, we should resort to early and

repeated physical examinations of the chest; a bacteriological examination of the sputum, if the disease has advanced to this stage; a microscopical examination of the blood; and, if doubt remains, we should finally resort to the tuberculin test. With the exercise of greater care on the part of both physicians and patients in recognizing the early symptoms of tuberculosis, and a more rational use of means to prevent infection, we may expect fewer cases of tuberculosis and a greater percentage of cures.

Three Cases Illustrating Cerebral Complications of Otitis Media Suppurativa. By Dr. Charles W. Richardson.—The difficulties attending work along the line of otitic cerebral surgery are pointed out. The localization of the lesion is not always clear; lesions may exist other than those made clear through the grouping of symptoms, and the pathological changes exposed may have progressed so far as to preclude the possibility of successful issues, all of which are independent, in the light of our present knowledge and skill in diagnosis and surgical intervention. The author earnestly advises that we report not only our successes but, more especially, our failures, as through them not only we, but likewise others, may profit. The author reports in detail two cases of fatal sinus thrombosis and one of cerebral abscess.

Suppurative Tympano-mastoiditis in Children. By Dr. Herman Knapp.—The author lays great stress upon the importance of an early diagnosis.

Some Observations in Mastoid Operations. By Dr. A. W. Calhoun.—The author calls attention to the infrequency of mastoid disease as compared with the large number of cases of suppurative otitis media; to the mild type of the disease; to the comparative exemption of the negro race; and to the presence of serious mastoid disease without marked outward symptoms and without apparent middle-ear involvement. Not every case requires radical operation.

Differential Diagnosis between Chicken-pox and small-pox. By Dr. Herman Spalding.

Misstatements on Antivivisection. Correspondence with American Humane Association. By Dr. W. W. Keen.—This article gives a letter from the president of the American Humane Association to Dr. Keen, and Dr. Keen's reply thereto is printed, in which he demonstrates that in the association's pamphlets entitled *Human Vivisection* there are vague and indefinite references and garbled and inaccurate statements.

Anastomosis of the Ureter with the Intestine. A Historical and Experimental Research. By Dr. Reuben Peterson.

Medical News, February 23, 1901.

The Value and Accuracy of the Röntgen Method of Diagnosis in Cases of Fracture. By Dr. Charles Lester Leonard.—Anatomical and surgical knowledge is as essential to the accurate employment of this method of physical diagnosis as it is to other methods. It must, however, be combined with the necessary technique in handling the apparatus, and with the clinical experience which fits the observer to make a correct diagnosis. Conducted by a properly equipped and competent observer, the author asserts that these examinations are invaluable in the diagnosis and treatment of fractures. Every medical society and medical community owes it to itself and to its patients to see to it that some one of its number possesses the knowledge requisite to the correct employment of this method for

the benefit of the community at large. The author advocates that whenever a skiagraph is introduced in court as evidence, the defendant should demand the privilege of having a similar examination made, and should employ expert testimony to fully explain its meaning to the jury.

Pharyngeal Adenoids and Hypertrophied Tonsils. By Dr. J. H. Woodward.—The author points out, as the symptoms common to all cases of adenoids, (a) hyperplasia of the lymphoid tissue in the vault of the pharynx; (b) chronic congestion of the submucous blood-vessels of the inferior turbinated body; (c) a more or less profuse mucopurulent discharge. The author calls attention to the facts that a certain development of lymphoid tissue in the nasopharynx is normal, and necessary to the patient's well-being, and that the so-called Luschka's tonsil is not a pathological structure, and that it becomes a pathological structure only when it has undergone hypertrophy or hyperplasia. Its function is to secrete mucus for the lubrication of the nasopharynx.

A Report of Some Cases of Abdominal Surgery, with Remarks on the Diagnosis of Carcinoma of the Cæcum and the Surgical Treatment of Carcinoma of the Liver and the Gall-bladder. By Dr. Charles Greene Cumston.—Of the difficulties with which the surgeon has to contend in operating on the liver, the author places first and foremost hæmorrhage from the hepatic parenchyma. The question of a proper incision in order to freely expose the tumor is also an important one for consideration; but he believes that, in the vast majority of cases, one carried along the border of the right rectus muscle will be quite sufficient for extirpation of the gall-bladder alone. He does not approve of the incisions recommended by Micheli and Lannelongue, on account of the complicated condition to which they give rise.

The Sustaining Treatment of Typhoid Fever, with Special Reference to the Use of Hypnotics. By Dr. A. H. Buckmaster.—The author sums up the sustaining treatment of typhoid fever by stating that no physician has done his duty who (1) does not know at the end of twenty-four hours that the patient has had enough food, water, and fresh air; (2) has allowed the patient to wear himself out by continued high temperature and lack of sleep—the amount of sleep within twenty-four hours should be recorded; (3) has not examined the urine frequently, and has not posted himself daily as to the condition of the urine, the movements of the bowels, and the condition of the skin.

Compound Dislocation of the Knee. By Dr. Walter Lathrop.—This case is interesting on account of its comparative rarity.

Nasal Obstruction; Mouth Breathing; Catarrh; Dilators. By Dr. Norburne B. Jenkins.—Many non-discharging obstructions may be treated with constant pressure. In the author's opinion this is best effected by the use of folded writing-paper dilators, in size about one half inch by two or three inches. For mouth-breathing during the night, the author recommends the use of a bridle, as a reminder to the patient, rather than as a means of locking the jaws. He points out, however, that in many mouth-breathers the muscles which hold the jaws closed may become atonic and may need the assistance of the bridle in overcoming the habit. To hygienic measures, without other treatment, many stubborn cases of hypertrophic rhinitis, middle-ear catarrh, amygdalitis, "bad colds," and arrested development may yield.

Lancet, February 9, 1901.

Gastric Hæmorrhage and its Surgical Treatment.

By A. W. Mayo Robson, F. R. C. S.—The author's article is based upon a series of five cases of gastric hæmorrhage treated surgically, and he urges the following conclusions: 1. All cases of acute uncomplicated gastric ulcer should be submitted to thorough medical treatment. 2. Where the ulceration proves intractable to medical treatment, or where relapses occur, gastro-enterostomy should be performed so as to secure physiological rest and relieve the hyperacidity of the gastric juice. 3. Perforation demands immediate surgical treatment. 4. The complications of disabling adhesions around the stomach and pylorus, pyloric contraction, hourglass contraction, etc., should be treated surgically. 5. In recurring or so-called chronic hæmatemesis from gastric ulcer, surgical treatment is decidedly called for. 6. In acute hæmatemesis, further accuracy in diagnosis as to the size of the bleeding vessels is urgently needed; the co-operation of the physician and surgeon is advisable in all such cases; but seeing that capillary hæmorrhage is capable of relief by medical means alone, medical should always precede surgical treatment. Of the author's five cases, four were successful; in the fifth case the cause of death was peritonitis, the result of leakage when the Murphy button used began to separate.

Considerations Touching the Pathology and Relations of Diabetes. By Dr. W. H. Dickinson (*continued*).—Some of the mystery which surrounds diabetes will be dissipated when an agreement is reached as to the bearing of the liver upon sugar. The author reviews the opposing theories of Bernard and Pary, but does not take sides. The treatment of diabetes gains little from pathology. We must presume that the disorder depends upon a lesion which is unknown in its fundamental part, though converging evidence assigns it to the nervous system. The essential lesion is not to be cured; we can treat the symptoms, however, and glycosuria, the most characteristic symptom, is the one most amenable to treatment. By diet we can always lessen the diabetic perversion, even where we cannot abolish it. That morphine, opium, and codeine lessen the excretion of sugar is certain, yet they disturb the normal functions and lead to constipation, and their careless use invites the onset of the peculiarly fatal coma of diabetes. In their stead the author advises the use of the nerve tonics, such as strychnine. A valuable remedy is water, soft water for choice, an eliminant that may postpone the coma that it cannot cure. Treatment in the future is more likely to rest upon improved physiology than upon the empirical use of drugs.

The Surgery of Pregnancy and Labor Complicated with Tumors. By J. Bland-Sutton, F. R. C. S.—In this article, which is the first of a series of three lectures on the above-mentioned subject, the author deals with ovarian tumors as complicating pregnancy and labor. Various illustrative cases are cited, and the author urges that when a puerperal woman known to possess an ovarian tumor exhibits unfavorable symptoms, ovariectomy should be resorted to without delay.

A Plea for the More Careful Study of the Symptoms of Perforation in Typhoid Fever with a View to Early Operation. By Dr. W. Osler.—The author calls attention to the fact that early diagnosis and early operation may save from thirty to forty per cent. of cases of perforation in typhoid fever. Up to January 1, 1900, there have been eleven cases operated on from his wards

with five recoveries, or 45.4 per cent. It is often a desperate remedy for a desperate condition. The vital point is to recognize the perforation and hand the patient over to the surgeon within twelve hours of the onset, before the perforation has become widespread. The author carefully reviews the various signs and symptoms of perforation. Sudden pain, increasing in intensity and recurring in paroxysms, is the most constant symptom of perforation. With an increase of the pulse rate, distention of the abdomen, increasing pain on pressure, and a rise in the leucocytes, the diagnosis is rendered probable. In a doubtful case operation should be urged. A general anæsthetic may not be needed, cocaine with a whiff of chloroform being all that is required. One of the author's patients recovered after three operations in two weeks, two for perforations and one in which a perforation was suspected.

Observations Based on the Probable Mode of Formation of Urinary Stone, Relative to its Recurrence and Prevention. By Reginald Harrison, F. R. C. S.—Though a stone may be successfully removed by operation, this does not necessarily imply that the original cause for its production has thus coincidentally ceased to exist. The class of cases where the tendency to recurrence is greatest and most difficult to deal with, subsequently to the primary operation, is that in which, before stone formed, the bladder was more or less functionally and structurally spoiled by the obstruction it had been submitted to by enlargement of the prostate (atony, cystitis, etc.). Recurrence in such cases may be combated in two ways: By local treatment of the bladder following operation, and by preventive treatment having regard to the probable mode in which urinary calculi are formed. When the condition of the urine after an operation remains abnormal, or unexpectedly becomes so, as indicated by appearance, smell, or microscopical examination, local treatment of the bladder by irrigation, etc., should be instituted, and should be continued until such states are removed. Plain soft water is the best irrigating fluid, but where there is an excess of mucus in the urine, a solution of nitrate of silver (one grain to twelve ounces) gives excellent results. As regards internal preventive medicinal treatment, the author does not believe that a stone, once formed, can be dissolved. But certain drugs are of great value in preventing ammoniacal decomposition of the urine and the excessive secretion of mucus, both of which are contributing factors to the formation of stone (alkaline salts, sandalwood, salicylate of sodium, urotropin, etc.). In conclusion, the author cites and discusses a series of cases which illustrate the various points brought out in his article.

On a Case of Myasthenia Gravis, Pseudo-paralytica; Death; Necropsy; Remarks. By Dr. I. G. Guthrie.

Ptomaine Poisoning or Perforation. By E. K. Brown, M. R. C. S.—The author reports the case of a woman, aged twenty-seven years, who was taken violently ill after eating sausages and died eighty-six hours after the onset of the illness. The points of interest about the case were: (1) The sudden occurrence of the semi-unconscious state; (2) the high temperature; (3) the absence of marked muscular weakness; and (4) the very intense inflammation in the peritonæum covering the intestine without any apparent inflammation inside, from which the toxic irritant presumably extended.

A Case of Cerebellar Hæmorrhage Presenting Well-marked Early Cervical Opisthotonos and Kernig's Sign.

By Dr. W. Thyne.—The author reports a case of cerebellar hæmorrhage occurring in a man aged twenty years, in which opisthotonos was present six hours after the onset of the illness, which had begun with vomiting. There was severe headache, the tendon reflexes were increased, and Kernig's sign was well marked. At the autopsy there was found a small hæmorrhage in the left lateral lobe of the cerebellum. There was no hæmorrhage over the base and no evidence of meningitis.

A Case of Pelvic Sarcoma with Chylous Ascites; Abdominal Section and Drainage; Patient Well Four and a Half Years after Operation. By Dr. A. W. W. Lea.

British Medical Journal, February 9, 1901.

A Case of Chronic Cancer of the Face. By F. T. Paul, F. R. C. S.—The author reports the case of a man, aged forty-three years, suffering from chronic cancer of the sweat glands of the face. At the age of nineteen years he fell and injured the skin over the lower margin of the left orbit. A small sore developed, which was excised thirteen years later. Three years later, when first seen by the author, he had a small excavated ulcer below the left eye, which was excised, the diagnosis being rodent ulcer. At the present time (eight years since the last operation) the whole left cheek is occupied by a tumor, which has destroyed the eye, and in the centre of which is a large, foul-smelling ulcer. In rodent ulcer or cancer of the sebaceous glands, while the growth is slow, yet the ulceration keeps pace with the growth, so that there is little or no tumor formation. Epithelioma, which is a carcinoma of the rete mucosum, grows in excess of ulceration similarly to the tumor here in question; but it rapidly infects the lymphatic system, and, unless removed, is quickly fatal.

On Ringworm Infection in Man and Animals. By Dr. J. L. Bunch.—Ringworm in human beings is usually due to two classes of fungus, the "microsporon" and the "trichophyton." The trichophyton class includes two forms: the ectothrix, both large- and small-spored, and the less common endothrix. The author has investigated the question of the ætiology of a large number of ringworm cases, and after careful search has been fortunate enough to meet with eight cases of ringworm in human beings, and also in animals with which they had respectively been thrown into intimate contact, to isolate and grow the fungus on culture media, both from the human being and from the animal, and to demonstrate the similarity between the cultures from the two sources. Cases of ringworm have from time to time been described as having an animal origin, but the source of contagion has hitherto only rarely been ascertained; indeed, in some of the previously reported cases the probability of the patients having contracted the disease from animals appears problematical. The author gives the details of each of his eight cases. The animals from which the patients had become infected were horses, cats, a dog, a canary, and a calf.

Remarks on Finsen's Light Treatment of Lupus and Rodent Ulcer. By M. Morris, F. R. C. S., and S. E. Dore, M. B.—The authors use exactly similar appliances to those employed by Finsen, but as sunlight is impracticable in England, they make use of electric light only. A current of about seventy-five ampères and about sixty volts is sufficient to produce a good reaction in most cases. The lenses must be clear and bright and the water clear and free from floating particles. The area treated

is, as a rule, kept well within the focus of the light; the smaller the focus, the greater the effect. The tubes must be kept in a straight line with the light rays, and the latter should fall perpendicularly on the compressing glass. Elastics are used to adjust the compressors to the patient's body, in preference to hand fixation.

The time of onset of the reaction varies from five or six hours to twenty-four hours. It is usually slight for the first few days of treatment, and then becomes more marked. If anything the intensity increases with continual treatment. After a preliminary hyperæmia with slight redness, a bleb forms, bursts, and dries, to form a thick, yellow crust at the end of a week. When situated over loose tissues, there is often great swelling of the neighboring parts.

The effect produced varies directly as the intensity of the reaction. Lupus vulgaris is the disease most benefited by this treatment, although it cannot be regarded as specific. It is also of great value in rodent ulcer and lupus erythematosus. The constitutional effects of the treatment are practically *nil*. Existing headache or neuralgia may be slightly aggravated. In treatment of the eyelids or canthi, no harmful effect is produced upon the eye itself.

Certain conditions make a case unfavorable for treatment. These are: A.—Those which *hinder the penetration of the light*, and so prevent a good reaction: 1. Scarring, especially from scraping, when the cicatricial tissue is, as a rule, very dense. 2. Pigmentation, which intercepts the ultra-violet rays. 3. Great vascularity. Unless the tissues are anæmic the rays will not penetrate. 4. Great depth below the surface, with which may be included thickness and induration of the nodules, surrounding inflammation and induration, and confluence of the nodules. B.—*Difficulties of position*, as, for instance, on the skin near the eye, where adequate compression cannot be applied, or on the mucous membrane of the interior of the mouth. C.—*Extent of the disease*. As only small areas can be treated each day, very extensive cases are unfavorable. The advantages of the method may be summed up as follows: Reliability, pain lessens, excellent cosmetic results; less liability to relapse; avoidance of surgical measures. Its disadvantages are the long time required, the small area treated at a time, and the expense.

In conclusion, the authors cite a number of cases which illustrate the conditions suitable for the application of the method and its effects.

A Preliminary Communication on the Treatment of Rodent Ulcer by the X-rays. By Dr. J. H. Sequeira.—The author reports a series of twelve cases of rodent ulcer which he has treated by the x-rays. The current used was one of from three to four ampères; the coil was one producing a ten-inch spark, and the tube was placed about six inches from the ulcer, the adjacent parts of the skin being protected by a layer of lead foil. The treatment lasted ten minutes and was repeated daily. So far the author has only treated cases deemed to be unsuitable for operation. Of his twelve cases, eight are still under treatment and four are under observation, the ulcers having healed. In no case has there been a disappointing result, and all the cases still under treatment are in various stages of healing.

An Address on the Need of Bacteriological and Pathological Laboratories in Dublin. By Sir G. Duffey, M. D.

The Surgical Treatment of Migraine. By W. Whitehead, F. R. C. S.—During the last twenty-five

years the author has never failed to treat successfully the most inveterate and severe cases of migraine by the introduction of an ordinary tape seton through the skin at the back of the neck. Ordinary half-inch tape is used, a fold of skin being transfixed by a scalpel, and the tape drawn through by means of a probe. Four inches of tape are left free at each side, which are tied together. The patient is instructed to move the tape from side to side each day. The seton should be worn uninterruptedly for three months, and should the symptoms recur a second seton should be introduced.

A Note on the Results Obtained by the Antityphoid Inoculations in the Fifteenth Hussars, Meerut, India. By Dr. A. E. Wright.—From a table given by the author, it would appear that the incidence of typhoid fever in the inoculated in the above-mentioned regiment was represented by 0.55 per cent., and the mortality by 0.27 per cent.; while the incidence in the uninoculated was 6.14 per cent., and the death rate 3.35 per cent.

On the Treatment of Superficial Syphilitic Gummata. By Dr. R. MacLaren.—The author recommends that superficial syphilitic gummata, which fail to improve under medicinal treatment with mercury and the iodides, should be excised. Where possible, the part to be operated upon should be made bloodless, as the yellow tissue of the gumma can then be distinguished from its surroundings with great certainty. A fortnight is a fair allowance of time to determine whether medicinal treatment is efficacious or not. It is not necessary to take away every particle of the altered tissue.

Progrès médical, January 26 and February 2, 1901.

Mountain Sickness. By M. E. Guglielminetti (*a continued article*).—The author thinks too little attention has been paid to the rôle played by decompression in the ætiology of mountain sickness. Vasomotor and cardiac stimulants are the principal agents of treatment, including the use of an artificial serum.

Lyon médical, January 27, 1901.

Chorea Treated by Cacodylate of Sodium.—M. Lanno reports three cases of Sydenham's chorea, all of exquisite type, which were cured by the use of cacodylate of sodium. It was given subcutaneously in doses of from one third to one half a grain. Although the cases are few in number, the author thinks that this drug should be extensively used in chorea.

Treatment of Vomiting of Pregnancy.—M. F. Morin believes the vomiting of pregnancy to be due to some gastric disorder. He gives a large dose of bicarbonate of sodium, thirty to forty grains at a time, upon an empty stomach. He has had very excellent results with this method of treatment.

Wiener klinische Wochenschrift, January 31, 1901.

Ligature of Umbilical Cord.—Dr. Maximilian Stolz has observed 500 infants in whom the umbilical cord was tied about one quarter of an inch from the umbilicus with fine silk, was divided with a sterilized scissors, dusted with dermatol, and covered with sterilized gauze. No bath was given until the cord had fallen off. In from two to three days the cord had entirely dried and began to separate. In consequence of the atrophy of the blood-vessels, the umbilicus retracted deeply and became squarely covered with skin.

Four Cases of So-called "Plastic Induration" of the Corpora Caverosa.—Dr. Otto Sachs writes an exhaust-

ive paper on this subject, giving clinical histories, symptoms, diagnosis, treatment, and prognosis. It should be read entire by those interested.

Operation for Ileus. By Dr. Josef Preindlsberger.—A clinical paper.

Centralblatt für Chirurgie, January 26, 1901.

On Quirol. By Dr. R. Schæffer.—A polemic article.

Technics of Gastro-intestinal Surgery.—Dr. Meinhard Schmidt suggests the replacing of pyloroplastic operations by completely occluding the pylorus and making a side-to-end anastomosis between the posterior wall of the stomach and the duodenum. By this means strictures will be avoided while the functional result remains very good. He advocates, too, the use of the Murphy button instead of the tobacco-pouch suture.

February 2, 1901.

Restoration of Divided Ureters by Direct Suture.—Professor A. von Gubaroff records the perpendicular suture of a ureter divided during operation. The free edge of the inferior segment was split perpendicularly, the upper end was invaginated into it, and the two ends were sewed together lengthwise. According to van Hook's experiments, longitudinal wounds of the ureter heal without fistula formation. The sutured parts were well covered with peritonæum. The patient died of some other ailment, and the ureter was found to have healed perfectly.

Treatment of Oblique Fractures of the Tibia by Extension.—Dr. Oscar Wolff recommends Bardenheuer's method of extension for fractures of the tibia. Thirty to thirty-five pounds counter-weight are to be employed, and the extension apparatus should be applied as soon as possible after the fracture, in order that the muscles may not have an opportunity to retract. The apparatus must remain in place for from six to eight weeks. Shortening is almost always prevented.

Sperimentale, Anno LIV, Fascicolo V, 1900.

The Action of the Nucleoproteids upon the Cells and Tissues. Experimental Researches. By Dr. Gino Galeotti.—The following conclusions were the result of this experimental study: The nucleoproteids extracted from the tissues of animals (kidneys, testicles), and those extracted from various species of germs (*B. pestæ*, *M. ureæ*, *B. prodigiosus*, etc.) show analogous chemical and physiological properties. They exercise considerable influence over cellular protoplasm in general, but the results of this influence vary according to the variety of cells attacked. Some cellular elements of mesenchymous origin respond to the influence of nucleoproteids with phenomena of irritation, but the epithelial elements under this influence show signs of intoxication, lose their functions, and degenerate. This fact corresponds to the well-established law that equal stimuli of equal intensity do not produce the same effect on different varieties of protoplasm. Thus the more resistant cells respond with reactive phenomena, while the less resistant ones are paralyzed. The chemico-physiologic action which the nucleoproteids exercise in the tissues is of two kinds. In some cases they cause the coagulation of either the liquid elements of the tissue (blood, interstitial exudates) or of proteids still contained in the cell body (coagulation necrosis of the renal epithelium, or of the hepatic cells). In other cases they produce a com-

plete disintegration of the anatomical elements. It is possible that the nature of their action may be analogous or identical with that of enzymes. It is astonishing that the nucleoproteids, which form such an essential part of the protoplasm, should have such a marked toxic effect upon the cells of some tissues. This fact simply shows the antagonism which exists between cells of different species, and between certain body fluids (serum) and the organized elements of a tissue which have an origin different from that of the fluid in question. Probably the destruction of certain cells represents the outcome of the struggle which goes on in the tissues in physiologic conditions, a struggle which, ultimately, is due to the action of substances that act like ferments. Ehrlich found that the destruction of red blood cells was due to a ferment which existed in the serum itself. It is probable that the cellulicidal action of certain body fluids and of certain cells of different (embryologic) origin from that of the tissues or cells acted upon depends on the toxic-fermentative function of the nucleoproteids. This hypothesis can be utilized in future investigations concerning the chemical and physiological antagonism of cells and tissues.

Alteration in the Secretory Function of the Salivary Gland. First Article: Experimental Rabies. By Dr. E. Zardo.—The author has studied the changes which take place in the process of salivary secretion and in the salivary glands of animals which have been inoculated experimentally with rabies. His conclusions are as follows: In the normal salivary gland there are probably two processes which constitute secretion. The first of these is the formation of liquid substances which results in the development of vacuoles in the gland cells; the second is the emission of solid particles which consist of fragments of protoplasm and cell nuclei. During the first few days after inoculation, the last of these processes is suspended, but it is intensified again later. The first, however, grows steadily more intense, so that the watery constituents of the saliva assume a greater and greater proportion, until, in the advanced stage, there is a veritable dropsy of the glandular cells. To this change, which is the result of a disturbance of the metabolism of the liquids in the cytoplasm, are due the alterations which are observed in these glands in animals inoculated with rabies. These changes may be summed up as follows: Swelling of the nuclei, indicating disturbances in the osmotic equilibrium of the nucleus and the cytoplasm, so that the concentration of liquids is less in the cytoplasm; karyorrhexis, indicating that the intranuclear osmotic pressure increases to such a degree as to overcome the resistance of the nuclear membrane; the disappearance of the chromatin, which, according to Arnheim, takes place when currents of liquid pass through altered nuclei; the presence of remains of the chromatin filaments which do not disappear entirely. The common observation that there is an increased salivary secretion in experimental rabies is therefore confirmed by histologic demonstration. It remains to establish the relation of the virus of rabies to this anomaly of secretion. But, first, we must know how salivary secretion behaves in the presence of chemical stimuli; such as pilocarpine, atropine, etc., or of physical stimuli, such as electricity. The author expects to report further results of his work in this field in the near future.

Concerning Skin Grafts. Experimental Researches Concerning the Duration of Vitality in Pieces of Skin Removed from the Body. By Dr. Pietro Pezzolini.—The author sums up the results of his experiments as

follows: 1. Strips of skin removed according to Krause's method, and preserved in normal salt solution for a time varying between twenty-four hours and six days, may be grafted on aseptic or well-granulating surfaces with good clinical results. 2. Mitosis takes place in pieces of skin preserved by this method for ten days, but only a few cells then take part in the process. 3. Preservation of skin grafts at a temperature of 0° C. may be said to be quite useful, for grafts six days old gave better results than strips of skin that had been preserved at the temperature of the room for the same length of time. In one specimen, mitosis and well-preserved cells were observed after eleven days' conservation at 0° C. 4. Preservation of strips dry in test tubes is not to be recommended, as the specimens so kept were found in bad condition two days after removal from the body. The mode of attachment of these grafts is the same as that of the freshly removed pieces of skin, but the preserved grafts grow less rapidly. When they once do take hold, the skin remains in good condition, and does not die and become replaced by granulations, as some authors maintain.

The Bactericidal Power of the Blood and its Alkalinity in Leucocytosis Due to Mineral Poisons. By Dr. A. Bentivegna and Dr. F. Carini.

Notes and Statistics Concerning the Treatment of Bubonic Plague in India. By Dr. A. Lustig and Dr. G. Galeotti.—This article is particularly interesting, as Lustig's serum is one of the preparations used in the struggle against bubonic plague in India. In summing up a review of the results of the prophylactic and curative administration of Lustig's serum, the authors say that this serum is the only preparation that has given satisfactory results, as proved by the experience of the health department of Bombay during the past four years. At present it is the only serum which is prepared in a special laboratory in Bombay (Parel Laboratory), and is widely used there both in hospital and private practice, while the other plague serums are practically abandoned. The sanitary authorities of Bombay are about to issue an official report which will give in detail the evidence concerning the value of Lustig's serum.

Vratch, January 6 (January 18, N. S.), 1901.

The Rôle of the Spleen in the Formation of Trypsin in the Pancreas. By Dr. A. A. Gertzen.—The author reviews the evidences obtained by experiments on animals by Schiff, Gertzen, and Pachon, showing that the secretion of trypsin is dependent upon the condition of the spleen. In an article published in *Vratch* a year ago, Popelsky gave an account of his experiments which were intended to prove the opposite. The author says that Popelsky's experiments do not affect the value of the researches of the other observers named above, as in his investigations Popelsky did not keep within the conditions of the question itself. The authors who maintain that there is a connection between the spleen and the secretion of trypsin have stated that this connection can only be observed during the act of digestion. The observations of Popelsky, however, were carried on before meals. Such experiments can only be compared to the attempts of a man to observe an eclipse an hour before the announced time, and who then declares that the astronomers were wrong. The facts upon which the assertions of the author and of Schiff and Pachon are based are as follows: The quantity of trypsin in pancreatic juice or in an infusion of the pancreas is proportionate to the swelling of the spleen, *i. e.*, the maxi-

imum amount of trypsin coincides with the maximum swelling of the spleen, while the minimum, which may equal zero, corresponds to the contracted condition of the spleen. In dogs and cats that receive food only once daily, the swelling of the spleen and the rapid rise in the amount of trypsin in the pancreatic juice begin simultaneously during the fifth hour after ingestion, reach their maximum during the seventh hour, and gradually subside. In animals deprived of the spleen there is no such rise of the amount of trypsin, but a total disappearance of this ferment from the pancreatic juice. If an infusion of splenic substance is added to a solution of protrypsin, obtained by extracting the pancreas of a starving animal, a very active ferment is at once obtained. The same result is obtained by the addition of venous blood flowing from the swollen spleen to the solution of protrypsin. If a dog deprived of its spleen is also deprived of one half the pancreas, and if an aqueous extract of the swollen spleen is injected, and after twenty minutes the second half of the pancreas is removed, the extract obtained from this portion of the gland will digest albumin, while that obtained from the first half will be inactive.

Concerning Writer's Cramp. By Dr. I. V. Zablou-dowsky.—A number of morbid conditions are collectively known as writer's cramp. This is the cause of the variety of opinions existing as to the treatment of this form of professional neurosis. The prevailing opinion as regards prognosis is that writer's cramp is an incurable affection. The cause of this is the fact that persons affected with writer's cramp often go to quacks who surround their methods of treatment with a halo of mysticism. The success of any method of treatment in writer's cramp does not depend so much on the ingenuity or complexity of the apparatus employed or of the physical methods of treatment practised, as on the degree to which the tired muscles are relieved of the strain in writing. Appliances facilitating writing can only be regarded as palliative measures, and cannot be considered as means of cure. The first essentials in the treatment of writer's cramp are the teaching of a proper method of writing and the training of opposing muscles to take the place of the tired ones, as well as the elimination, so far as possible, of the pressure points in the movements of the hand. Massage may be advantageously combined with these exercises. The use of exercises in writing large letters at first, using the whole wrist in the movement, then in writing smaller letters, until the ordinary size of writing is reached, is very beneficial, as it trains the wrist movement. Cramp may be prevented by relaxing the muscles engaged in writing and moving the whole hand a short distance after every two or three words. In this way an uninterrupted line is obtained, but the muscles get enough rest between every effort. In the same manner it is advisable to interrupt the movement of the pen in tracing letters or words that require prolonged efforts. In the more severe cases of cramp, some appliance must be used which will relieve the muscles from tension. A sliding rest for the right elbow, hanging on a horizontal arm fixed above the table, is such an apparatus. If the cramp depends on central disturbances, *e. g.* hysteria, the local treatment must be combined with general measures. Suggestion combined with massage gives good results. The use of exercises analogous to the Swedish system of gymnastics is of but limited value, as the movements mentioned are comparatively coarse. The use of typewriters, and the increased attention to

methods of teaching writing, will eventually lessen the frequency of writer's cramp. (*To be continued.*)

The Diagnostic and Prophylactic Value of Koch's Tuberculin. By Dr. Th. A. Dombrowsky.—The use of tuberculin for diagnostic purposes, in view of the perfect harmlessness of the remedy, may be looked upon as a most valuable means of distinguishing the various stages of tuberculosis, and may be employed without fear of untoward manifestations in the proper cases. Before using tuberculin for this purpose, however, one must always make a thorough clinical examination, and tuberculin is only to be injected in the absence of physical signs or in the presence of indefinite signs, when tuberculosis is suspected.

Electrolysis in Cicatricial Stenosis of the Œsophagus. By Dr. N. V. Sletoff and Dr. P. I. Postnikoff.—A little over two years ago the authors published an account of their first successful case of cicatricial stenosis of the œsophagus treated with electrolysis. During the past year they have seen a second case of this kind, and now give the history of this patient. The principle of electrolytic treatment in these cases is the destruction of the new connective tissue by means of chemicals which form at the negative pole—caustic soda and caustic potash. The slough thus formed falls off and the ulcer heals without any secondary cicatrix. The chief advantage of electrolysis over other caustics is that it does not affect the surrounding tissues, but can be limited to a locality with great accuracy. For this reason it is applicable in such places as the urethra, the œsophagus, etc. Why the electrolytic products affect the scar only and not the surrounding tissues, cannot be stated with certainty, but it is known that a much stronger current is required to destroy old, already organized tissue than that which is sufficient to destroy new connective tissue. Probably the difference is caused by different conditions of conductivity and resistance. The authors measured the thermo-electric coefficient of the œsophageal electrode while it was doing the work of destroying the cicatrices, and found that the heat developed was so infinitesimal that the process could by no means be called a thermo-cauterization. No dilatation is employed, as the olive of the electrode is held on the cicatrix only by its own weight. The olive-shaped electrode is to be preferred to the linear one used by Fort. The technique is simple. The broad plate, representing the positive electrode, is placed on the abdomen or on the back of the patient. The negative pole of the battery is connected with a copper rod, the end of which is provided with a screw thread, on which the olives are screwed. The latter are of copper, silver, or nickel, ranging in size from one half to two centimetres in diameter. After the olive has been introduced and has been felt resting against the obstruction, the current is turned on, and the galvanometer, pulse, and facial expression, as well as the time of application, are observed, until the olive slips through the obstruction. The current is then closed and the sound removed. The pain is slight. The appearance of blood on the olive indicates too long a *séance* or too strong a current.

Bulletin of the Johns Hopkins Hospital, December, 1900.

Theodor Billroth. Musical and Surgical Philosopher. A Biography and a Review of his Work on Psycho-physiological Aphorisms on Music. By Dr. John C. Hemmeter.—Although no such contribution to localization as that of Broca has been made by Billroth in his psycho-physiological aphorisms on music, nevertheless his work

will prove of value, because of the general clearing of the entire subject of physical and physiological acoustics, and by rendering the work of Helmholtz more accessible and more intelligible to musical artists and connoisseurs, so that they may hereafter become conversant with the scientific aspect of their art. Above all, by pointing out the gaps and breaks in the experimental and practical logic, he has emphasized the gaps that must be filled before we may hope to reach more tangible results concerning the purely psychological aspects of music.

Report on the Examination of the Ears of Four Hundred and Forty School Children. By Dr. H. O. Reik.

Experimental Injection of Testicular Fluid to Prevent the Atrophy of the Prostate Gland in Dogs, after Removal of the Testes. By Dr. George Walker.—The injections had apparently no effect whatever, and the author concludes that the atrophy of the gland is in no way connected with the absence of any substance in the testicular secretion.

A Plea for Early Naked-eye Diagnosis and Removal of the Entire Organ with the Neighboring Area of Possible Lymphatic Infection in Cancer of the Larynx. By Dr. John N. Mackenzie.—Not until the conscientious surgeon removes not only the entire organ, but also the neighboring lymphatic area, in cancer of the larynx, will the statistics and prognosis become more favorable. It is chiefly because they have not been complete, that incision of half the larynx or of the whole organ has so signally failed in the past.

Heredity in Diabetes Mellitus, with a Report of Six Cases Occurring in a Family. By Dr. J. Hall Pleasants.

THE NON-OPERATIVE TREATMENT OF PROSTATIC HYPERTROPHY, WITH SPECIAL REFERENCE TO CATHETER LIFE.

BY RAMON GUITÉRAS, M. D.,

NEW YORK.

IN the non-operative treatment of prostatic hypertrophy "catheter life" plays an important rôle, and it is my intention in this paper to pay special attention to that phase of the conservative treatment of hypertrophied prostate which concerns the use of the catheter.

By "catheter life" is meant the habitual use of the catheter to which men of a certain age are obliged to resort in order to rid themselves of a given amount of urine which otherwise they would be unable to void, on account of the impediment in the posterior urethra caused by the enlarged prostate. Such a life is begun in cases of prostatic hypertrophy with complete or partial chronic retention, or during attacks of acute retention; in other words, either when only a part of the urine can be voided and enough is left behind as residual urine to interfere with the health of the patient, or when no urine can be passed spontaneously. The popular interpretation of catheter life is that it is a measure to be adopted when nothing can be passed. Naturally, complete retention is the form which most demands the

catheter, for if nothing were done to relieve a case of this kind, the bladder would dilate to such a degree that either it would probably rupture or the ureters and the pelves of the kidneys would dilate until sufficient pressure was brought to bear upon the kidney proper to interfere with its function and to cause death from uræmia. Nature, however, usually protects the patient from such a fate by relaxing the sphincters and allowing an overflow of the contents to take place. When the upper sphincter, or sphincter vesicæ proper, gives way, the urine reaches the posterior urethra and gives rise to a desire to urinate, and then everything possible is squeezed out in an act accompanied by painful tenesmus.

In unrelieved cases of partial retention the residual urine present gives rise to enough bladder irritation to cause considerable suffering, and generally develops an obstructive cystitis, which may be followed later by ureteritis, pyelitis, and pyelonephritis, and may end in death from uræmia or from septicæmia as surely as in cases of complete retention, though more slowly.

In order, then, to consider the subject of the conservative treatment of prostatic hypertrophy as it presents itself to the general practitioner, it is not enough to say: "Catheterize your patient as often as is necessary to relieve him of his accumulated residual urine, washing out the bladder as frequently as is indicated," but we must consider all the principal features that may present themselves—the symptoms; the complications existing at the time the patient comes to us; the complications that may follow catheterism, and the methods of avoiding them; the treatment by palliative means; the aseptic precautions and the technique connected with catheterism; and the directions to give the patient about the use of the catheter.

Symptoms.—The symptoms of prostatic hypertrophy are a feeling of fulness in the perinæum, urinary tardiness, a slow stream, sometimes dribbling, frequency of urination, burning in the neck of the bladder, tenesmus and irritability, pain in the perineal, epigastric, sacral, or lumbar region, and retention or incontinence of urine. These symptoms may all be due principally to the prostatic enlargement, or they may be due to the complications which sometimes develop in its course. The complications are urethritis, prostatitis, epididymitis, cystitis, ureteritis, pyelitis, hydronephrosis, pyonephrosis, pyelonephritis, urethral fever, suppression, acute renal congestion, and uræmia. Many of these complications may follow catheterism and prove most alarming, for it must be remembered that the use of instruments is the most frequent cause of infection in prostatitis.

General Treatment.—The palliative treatment of prostatic hypertrophy is directed to the relief of the symptoms and to the prevention of complications. It consists in the administration of diluents, antispasmodics, internal urinary antiseptics, and laxatives, and in hot baths, hot local applications, rectal douches, prostatic massage, catheterism, bladder irrigation, aspira-

tion, and the regulation of the diet, clothing, and exercise of the patient.

The conditions giving rise to the symptoms enumerated in the preceding paragraph are: 1. Partial retention, with or without cystitis. 2. Partial retention with an acute attack of complete retention. 3. Complete retention. It is the symptoms of bladder irritation or of cystitis due to retention, or the retention itself, which demand treatment in these cases. As a general rule, there is frequency of urination, with, perhaps, bladder tenesmus and pains in the perineal, hypogastric, lumbar, or sacral region. These may be due to congestion of the prostate or bladder, or to cystitis. The intensity of these symptoms varies according to the intensity of the inflammation or congestion, and, to a certain extent, with the susceptibility of the patient to local irritation. It is impossible to say why some patients suffer more than others, or to predict which patient will suffer the most, for patients with normal urine and a prostate which is but slightly enlarged will sometimes suffer more than others with marked cystitis and a very large prostate.

The cystoscope has, in my mind, cleared this interesting question in many cases, as in cystoscopy in cases of marked irritability without cystitis I have often seen large varicose veins of the vesical neck and trigonum, which are probably sufficient to account for the discrepancy in the proportion of symptoms to lesions.

In prostatic hypertrophy the first step, after establishing the diagnosis, is to determine the condition of the urine and the amount of residual urine present.

Congestion.—If the urine is found to be normal, we can attribute the symptoms to congestion, and, all other causes of congestion or irritation around the neck of the bladder having been excluded (such as gonocystitis, stricture, tuberculosis, stone, or tumor), we conclude that the cause of the symptoms is the hypertrophy of the prostate and the consequent congestion of the bladder neck through an interference with the vesical circulation. A soft-rubber, velvet-eyed, elbowed catheter should then be introduced into the bladder after the patient has urinated, in order to see how much residual urine remains. If the residuum is less than two ounces, an attempt should be made to relieve the congestion and to diminish the discomfort by internal and local remedies without the use of the catheter, in the hope that this instrument need not be used for a while, and that the amount of residual urine, which is small, may be diminished.

To alleviate these symptoms, then, a diluent and an antispasmodic may be given to render the urine which comes into contact with the congested surface less irritating, and to calm the sensory nerve fibres in this region, in the hope that, temporary relief being given, the symptoms may be held in abeyance for a while. As a diluent, plain water is of service, but the saline diuretics are perhaps better, as, in addition to producing an

increased flow of urine, they also neutralize it. For this purpose the potassium salts are generally prescribed either the citrate, the acetate, or the bicarbonate.

Of the antispasmodics, belladonna is the best, though many prefer hyoscyamus. Codeine is also of service, as is morphine, but if it is possible to avoid the latter opiate should not be prescribed internally. A preparation of value to administer internally in such cases is:

R Tincture of belladonna..... 7½ drops;
Potassium acetate.15 grains;
Peppermint water, enough to make 1 drachm.

S. A teaspoonful three times daily between meals.
Another prescription for the same purpose is the following:

R Codeine. ½ grain;
Tincture of belladonna.....10 drops;
Potassium acetate.15 grains;
Peppermint water, enough to make 1 drachm.

S. A teaspoonful three times daily in a glass of water.

Sometimes these patients do not find the desired relief, in which case a suppository at night will help to diminish the discomfort.

R Extract of belladonna, }
Morphine sulphate, } each. ¼ grain.

Hot rectal douches of saline solution taken by means of the recto-genital tube before going to bed are also of benefit, and the same may be said of sitz-baths.

The various bladder specifics, such as saw palmetto, corn silk, and buchu, sometimes give relief, but they are uncertain and, at present, not much used.

Moderate exercise should also be recommended, but it must be such as to increase the general circulation without favoring local congestion. Walking is one of the best means of exercise, but this should be brisk and followed by a "rub-down" and a change of clothing. There are forms of exercise that a man of the prostatic age cannot take; he certainly cannot indulge in the so-called athletic sports, and the bicycle and riding on horseback do him harm. Probably golf is the best exercise for such men.

Fresh air is, of course, of great benefit, but the man in taking it should be on his guard against exposure to wet and cold. The clothing is also important. Wool should be worn next the skin, and when the patient has perspired he should change his clothes, instead of allowing them to dry upon him, especially if it is cold. The feet, above all, should be kept warm and dry. These remarks may seem unnecessary, but such hygienic measures are of the greatest importance, for they tend to prevent congestion, which gives rise to attacks of acute retention, and to improve the general tone and vigor of the system, thus fortifying it against infection. Exposure to cold and wet may also produce attacks of acute congestion of the kidneys, and these may be followed by uræmia. Too much, therefore, cannot be said

of the importance of preventing prostatics from becoming chilled. If possible, they should go to an equable climate for the winter—for example, to Nassau, in the Bahamas. One notices that the prostatic usually fades away and dies in the fall of the year, with the onset of cold weather.

The care of the bowels should also receive attention. Some laxative should be given which will produce one good movement every morning. Cascara sagrada, given at night, is a trustworthy remedy. The dose varies with the susceptibility of the patient to this class of drugs. Saline aperient waters also, given in the morning, are of value.

Local Treatment; Catheter Life.—If no relief is obtained by the general measures above described, and if the amount of residual urine seems to be increasing, the use of the catheter to empty the bladder before going to bed at night, and bladder irrigation with a solution of boric acid, or of some preparation of it, may be tried. If there are from two to five ounces of residual urine, and the symptoms are distressing, the patient should be catheterized once a day, morning or evening. If the amount of residual urine is greater—say from five to eight ounces—it should be drawn off twice a day, night and morning, great care being taken to keep the catheter clean and to employ the technique described further on. In such cases, no cystitis being present, there will be no necessity of washing out the bladder, unless with the expectation of relieving any bladder irritability that may be present.

If the amount of residual urine is found to be from eight to twelve ounces, the patient should catheterize himself three times daily. If it is from twelve to sixteen ounces, catheterism four times a day will be required. Twelve ounces is the normal average amount voided by a man in health at the usual intervals of urination—*i. e.*, in the morning, at night, and perhaps two or three times during the day—and if the residual urine amounts to this quantity, the bladder is practically in a condition to demand catheter life. As a pint is usually sufficient to cause an imperative desire to urinate, if a patient has that quantity of residual urine, in order to pass away the amount in excess of that which is constantly being secreted by the kidneys, he would be obliged to pass urine very frequently, or else he would have an overflow-retention.

Such is really incomplete retention, but retention of sufficient importance to call for the use of the catheter, as otherwise the back-pressure might produce serious complications.

So far I have spoken of *incomplete retention*. If in any such case a pronounced excess of urine has accumulated in the bladder, either an overflow-incontinence will have resulted or else an acute attack of *complete retention*. Such a complete retention, occurring in a patient who has a greater or less amount of residual urine, may depend upon the patient's postponing the emptying

of his bladder until the contents have overcome the resistance of the bladder wall; in other words, until the urine has dilated the bladder wall to such an extent that its contractile power is interfered with, as when a man is intoxicated, or while driving, or sailing, or in some other situation in which he cannot urinate when the desire comes.

As a rule, however, these attacks are due to prostatic congestion or œdema, brought about by exposure to wet and cold, thus chilling the extremities and causing a determination of blood to the prostate. In these cases the patient suffers considerably. He has pain and a cramp-like feeling in the suprapubic region, a desire to urinate, but an inability to do so, and generally a little dribbling.

When a patient is seen in this condition, the greatest care must be taken in handling the case, as it means suddenly breaking a patient into catheter life, and it is a crisis in his existence. The dribbling and incontinence may be sufficient to prevent death from hydronephrosis and consequent uræmia, but, the bladder wall being considerably dilated, the blood-vessels are being more and more pressed upon, and the muscular tissues are being distended and weakened. The patient in this condition always seeks relief. Very often the physician draws off all the urine and a congestion of the bladder takes place, and the urine accumulates again, but this time the congested bladder is more irritable and cannot contain so much urine as before. The suffering is intensified, and the patient again seeks relief. This continues; the bladder congestion increases, pain, tenesmus, dribbling of urine mixed with blood and pus (if infection has taken place) being almost constant. This is the picture that presents itself when the patient has escaped death, but, unfortunately, he has suffered greatly, and in all probability will suffer still more from the cystitis which is almost sure to follow.

In such cases the following course must be pursued by the surgeon: He should insert a sterilized catheter lubricated with sterile glycerin, or some bland lubricant, through the urethra into the bladder, and draw off a quantity of urine not exceeding sixteen ounces. He should not draw off the entire contents, as in these cases several quarts may have accumulated, and in this event there may be fatal syncope or an acute congestion of the entire urinary tract due to the rush of blood to the urinary organs after the back-pressure has been removed, and this acute congestion in a kidney affected with Bright's or with some surgical disease may interfere with the functional activity of the organ and inhibit the requisite excretion of urea, thus producing uræmia. As hæmaturia and death from renal congestion have occurred after the removal of twenty ounces of urine, it is safe to put the limit as a hard and fast rule at sixteen ounces. The patient should be put on the use of a urinary antiseptic, an opiate should be given to relieve the pain, and a hot sitz-bath should be ad-

ministered, or a hot rectal douche, together with the use of hot fomentations over the suprapubic and the perineal regions.

If in two hours the patient is able to pass a fair amount of urine spontaneously, he should be allowed to void it at intervals of an hour or two. If he cannot void it at the end of four hours, the catheter should be again inserted and twelve ounces should be withdrawn, and the same amount again in three hours. After this, eight ounces can be withdrawn every two hours until the bladder is empty or until the patient has regained the power of spontaneous urination.

In case the physician, on visiting the patient in this condition, cannot pass the catheter, which, by the way, should be an elbowed, soft-rubber, velvet-eyed instrument, No. 12 to 14 French, he should give the patient an opiate hypodermically and order a hot sitz-bath. Very often the patient can pass some urine in the bath. If not, after an hour's rest the physician should again try to pass the catheter. If unsuccessful after two or three attempts, he should puncture the bladder suprapubically with an aspirator and withdraw not over a pint of fluid. Then hot applications should be made above the pubes, and usually the patient will be able to urinate spontaneously after an hour or so, or else the catheter can be passed. If not, the patient should again be punctured at the end of from four to six hours, and this procedure should be repeated at these intervals until the prostatic congestion has gone down sufficiently to allow of spontaneous urination or to permit the introduction of a catheter. Generally a few punctures will suffice. There are cases in which 150 punctures have been performed.

When the patient has begun to urinate spontaneously, the physician can determine the amount of residual urine present, and can use the catheter at intervals the frequency of which is indicated by the amount thus found, according to the rules already given.

In case the patient has no spontaneous urination after the catheter has been used for several days, and if he has pain or tenesmus when from twelve to fourteen ounces have accumulated, then constant catheter life will probably have to be begun, and the frequency of using the catheter will depend upon the individual case.

Catheter life is usually introduced by an explosion which takes place when the patient is leading a methodical life, without thought of having to resort to artificial means for urination, the explosion being an acute attack of retention, such as has been described above. The explanation of this is as follows: A certain amount of residual urine had been present perhaps during a considerable period of time without the patient's knowledge, and then an acute congestion of the prostate took place and acute retention occurred in consequence. Although there are many cases in which the patient has never had retention, but consults his physician for a feeling of local weight, and it is found that he has from six to

twelve ounces of residuum, there are other cases in which the patient knows he has prostatic hypertrophy and has been using the catheter right along, but suddenly the retention becomes acute, and the treatment described above has to be resorted to. When the daily use of the catheter has to be resorted to, the patient has to be shown how to pass the instrument himself, and the surgeon should not only furnish him with directions for doing this, but should teach him personally the details of the technique of catheterism. The catheters used should be of soft rubber with elbowed end and velvet eye, No. 12 to 16 French, and they should be bought by the dozen in assorted sizes, so that the patient may never find himself without the proper catheter, and may always have another one at hand if one fails to enter. It must be remembered, also, that catheters lose their tone and become roughened by sterilization. If the patients cannot use the soft-rubber catheters, they may be given the woven variety of the same shape and size. As catheter life is a very important matter for the prostatic patient, he should be properly equipped for the same, just as he is equipped with proper clothing for the different seasons. He should, therefore, purchase a small sterilizer, in which the catheters can be boiled over a small gas stove, or, if he is obliged to use the woven catheters, a small formalin sterilizer.

The physician should prop the patient up on a bed or sofa, should take a sterilized catheter, dip it into a bottle of glycerin that has been previously sterilized by placing the bottle in water up to its neck and boiling the water, and, holding the catheter by the distal end, should open the lips of the meatus, the glans having been cleansed, and let the proximal end of the catheter dangle over the opened meatus until the end is engaged. Then the catheter should be allowed to drop, partly of its own weight, partly impelled by a gentle impulse, down into the urethra as far as it will go. If the catheter stops, the surgeon must bring his hand down further on the instrument and gently guide it past the impediment in the prostatic urethra, or through the compressor urethræ if this is in a spasmodic condition. The catheter must now be given into the hands of the patient, and the surgeon should watch him as he passes the instrument, instructing him as he goes along. It may take several days of such instruction before the patient can pass the catheter into his bladder, but after he has mastered this procedure he should be allowed to pass it on himself as often as is necessary. The surgeon should, however, see the patient as often as is needed to treat the cystitis which is generally present and to continue the observation of the case.

Very often a patient broken into catheter life will be able to catheterize himself much more easily than this can be done by the physician; on several occasions the writer has failed to pass a catheter on patients who could perform this procedure very easily upon themselves. On the other hand, on many occasions the sur-

person can pass the catheter on patients who cannot do so, owing to nervousness and lack of confidence. The only catheters which the writer would recommend are the soft-rubber and the woven ones, and no other varieties should be used by patients who catheterize themselves. The care of these instruments is comparatively simple, and yet it is very important that the patient be properly instructed in the manner of taking care of them if he is to lead a catheter life. Perfect sterilization of a soft-rubber catheter can be secured by boiling it for five minutes, and perfect sterilization of a woven catheter can be obtained by subjecting it for from five to ten minutes to the fumes of formalin. The formalin sterilizer resembles a tin bread-box in shape. In this box is an alcohol lamp, and on the chimney of the lamp is a cup, into which the pastille of formalin is placed. A shelf in the box serves for the catheters to be disinfected. After the catheters have been placed on this shelf, and after the lamp has been lighted and the tablet put into the cup, the door of the box is closed and the catheters are allowed to remain in the formalin fumes for five or ten minutes. This process can be carried on with woven catheters for an indefinite number of times, whereas if they were boiled they would be speedily destroyed. All catheters should be washed with soap and water and flushed out with warm water as soon as possible after they have been used, and again before sterilization.

When the patient goes to business in the morning, he should take his catheters, previously sterilized, wrapped up each in a sterilized towel and placed in his pocket. He should also take along a bottle of the sterile lubricant. When the time comes to pass his catheter, he should unwrap one catheter and let the end of the instrument drop into the lubricant. Holding the lips of his meatus open with one hand, he should next drop the catheter into the urethra and guide it past the obstruction, as already indicated. After using, he should wrap the soiled catheter in another towel and place it in another pocket. This procedure should be repeated during the day as often as is necessary, the frequency depending upon the urgency of the desire to urinate. On arriving home at night, the patient should wash the catheters, flush them out, and sterilize them again as directed, wrap them in a sterilized towel, and take them down to business in the same way on the following day.

Complications of Catheter Life.—Attacks of *acute retention* due to congestion or œdema of the prostate have already been spoken of. They are such frequent complications of prostatic hypertrophy as to constitute a part of its symptomatology. Next in frequency is *cystitis*. The treatment of cystitis in these cases should consist in washing out the bladder once or twice daily, in addition to the measures indicated under the heading of General Treatment. If the bladder is washed out every other day, the best treatment is by irrigation with weak solutions of silver nitrate, the usual strength being

1 to 3,000, given through the catheter. If the bladder is washed out once a day, a still milder solution of silver nitrate is indicated. It is often advisable to wash out one day with a saturated solution of boric acid, and the next day with a silver-nitrate solution. If the patient is directed to wash his bladder out twice daily, he should use either a saturated solution of boric acid throughout or one injection with boric acid and the other with silver nitrate. The technique of these irrigations is very simple, and they can easily be performed by the patient himself. A fountain syringe is hung up above his bed, and at the end of the tube a coupling nozzle is attached. The reservoir (bag or can) is filled with hot boric-acid solution. Before getting up in the morning the patient passes the catheter, draws off the urine, and leaves the instrument in place. The coupling nozzle is next introduced into the distal end of the catheter, and the patient allows the fluid to run into the bladder until it feels distended. He then withdraws the coupling and allows the solution introduced to run out into some vessel between his legs. This procedure is then repeated until the bladder has been thoroughly cleansed. At night, before he goes to bed, the same treatment is repeated. The fountain syringe (one of glass is to be preferred) can remain on the wall, and the end of the tube with the coupling nozzle can be dropped into a bottle containing a 1-to-2,000 bichloride solution standing on the floor under the bed. After a little practice the patient himself can attend to these irrigations as well as any one. He makes the boric-acid solution by adding a tablespoonful of the powder to a pint of water, and the silver-nitrate solution, 1 to 4,000, by adding four drops of a grain-to-a-drop solution in a quart of water, or eight drops for a 1-to-2,000 solution, if desired. These solutions should be as hot as can well be borne.

The next complication of catheter life which I shall consider is *urethritis*. This complication comes about in one of three ways. In the first place, it may occur in those cases in which the catheter has to be retained for continuous drainage, thus giving rise to a constant irritation of the urethral wall and an opportunity for some urine to pass down alongside the catheter, decomposing and acting as an irritant. Secondly, urethritis may develop as a result of unclean catheters or of rough catheters which produce traumatism along the urethral wall as they are passed in. Thirdly, a specific urethritis may occur when the physician has used a catheter in the urethra of a prostatic patient after having used the same instrument in a case of gonorrhœa. In such cases urethral irrigations of potassium permanganate, from 1 to 4,000 to 1 to 1,000, or of silver nitrate, from 1 to 8,000 to 1 to 4,000, will usually cure the inflammation in the urethra, or an ordinary hand-injection, such as is given in attacks of gonorrhœal urethritis, may be ordered. It may be noted, however, that urethritis but rarely occurs in these cases without cystitis, as the same catheter is used in the bladder as that which infects the urethra.

As the result of an inflammation of the prostatic urethra, another complication may ensue, namely, *epididymitis*. It must be remembered that in prostatic hypertrophy the posterior urethra is extremely sensitive, and the repeated traumatism of a catheter, in the endeavor to pass through the contracted sphincter, aggravates the congestion of the mucous membrane and prepares a favorable soil for infection. The inflammation in the prostatic urethra can easily extend down through the ejaculatory duct and give rise to epididymitis. The fact that this complication may occur shows the importance of care and gentleness in passing the catheter. If the sphincter rebels against the entrance of the catheter into the bladder, the patient should not force the instrument in, but should take a hot sitz-bath or a hot urethral irrigation of saline solution, and then rest for a while. Then he can employ another catheter, perhaps one of smaller size, with more gentleness. Epididymitis is one of the most distressing complications that occur in prostatic hypertrophy, and patients have frequently applied for a radical prostatic operation on account of the recurrent epididymitis from which they suffer. The treatment of this complication is the same as that of epididymitis due to any other cause. The inflammation is usually not so severe as that following gonorrhœa and generally subsides in a few days. A fifty-per-cent. ichthyol ointment or a poultice for two or three days is generally sufficient to make the acute symptoms disappear and enable the patient to resume his duties. Some urinary antiseptic, such as salol, urotropin, eucalyptol, or a benzoate, should also be administered in order to render the urine less infectious.

Finally we come to a group of complications of prostatic hypertrophy which depend upon the pressure of the urine which cannot find its way into the urethra, on the transmission of infection from the bladder upward, on reflex irritation of the kidney, or on a combination of these causes. In this group are included ureteritis, pyelitis and pyelonephritis, hydronephrosis and pyonephrosis, urethral fever, fatal syncope, acute renal congestion, acute nephritis, suppression of urine, and uræmia.

Ureteritis, Pyelitis, and Pyelonephritis.—This group of affections is due to an increased pressure in the urinary tract, combined with transmission of infection from the urethra and bladder. The ureters and pelves of the kidneys are, as a rule, the first seats of infection, but after a while the tissue of the kidney itself may become affected, the resulting condition being pyelonephritis, or "surgical kidney," as it is sometimes called. When pyelitis alone is present, there is, in addition to the local symptoms due to the obstruction, an occasional pain in the region of the kidneys, both on pressure and on motion.

The symptoms of pyelonephritis are, in addition to those described above, fever, headache, anorexia, dry tongue, nausea, vomiting, a tendency to somnolence, and a facies which is characteristic of systemic septic poi-

soning—sallow, emaciated, pale, and anxious. The attack may be preceded by a marked chill. The prognosis is very unfavorable, especially if both kidneys are involved, and but little can be done in the way of treatment except to remove so far as possible the local causes—the retention and the decomposition of urine and absorption of pus. It is to be remembered that any manipulation of instruments must be very cautiously performed, as the kidney may be still further irritated reflexly and still more septic material may be introduced with the catheter.

The urine must be drawn off with sufficient frequency to relieve the back-pressure. In cases of urethritis and pyelitis large quantities of water and urinary antiseptics should be given. If pyelonephritis is present, nephrotomy and drainage are the only means of saving the patient. The urine from each kidney should be examined to ascertain the condition of the organ, as nephrotomy should be performed only on one side at a time.

Hydronephrosis.—As the result of the obstruction there is sometimes an unusual dilatation of the pelves of the kidneys. As these become larger under the influence of increased pressure, the calices of the kidney are also dilated. This condition is a double one, as the obstruction is below the ureters. The treatment consists in treating the bladder as already described under Retention.

Pyonephrosis means that in addition to dilatation there is suppuration in the pelves of the kidneys. The suppuration may be present from the first, or it may follow hydronephrosis. The symptoms are similar to those of pyelitis with the enlargement of the pelvis. This is never marked in prostatitis and usually affects both kidneys. The treatment is the same as for pyelitis and hydronephrosis.

Urethral Fever.—This term is used to designate a febrile disturbance which results from the passage of an instrument or the performance of a surgical operation on the urethra. The fever is, as a rule, due to absorption of some septic material from the urine which passes over an ulcerated surface in the urethra. It is to be noted that the quantity of infectious material necessary to produce urethral fever varies greatly, for in some cases a small erosion is sufficient, while in others large operative wounds are bathed with the same urine without causing any rise in temperature. Urethral fever, I may here add, is also a name applied to the fever due to acute renal congestion and acute interstitial nephritis or to suppurative pyelonephritis—conditions which I have described under special headings.

If an erosion is present in the urethra, the patient should be put on the use of some urinary antiseptic, such as one of the benzoates, a salicylate, or urotropin, and the urethra should be irrigated with a silver-nitrate solution at varying intervals. Bladder drainage by means of a retained catheter or a perineal section, with

daily irrigations, is often the only means of relieving the patient. A suppository containing half a grain of morphine and ten grains of quinine may also be given before each introduction of the instrument, to prevent an attack. Patients who are being broken into catheter life often have an attack of chills and fever and sweating occurring singly or in several attacks over a prolonged period of time, and they often attribute these symptoms to malaria, or, when they are accompanied with nausea and vomiting, to indigestion, or to some other gastrointestinal disorder. These symptoms are, however, due to septic absorption through the urethra. It may be stated, as a rule, that all "malaria" arising and existing during urethral interference is sepsis.

Fatal syncope occurs when the bladder is suddenly emptied of a great amount of fluid, owing to the rush of blood into the veins, whose walls have been rendered parietic by pressure. This would never occur if the dilated bladder were emptied slowly and at regular intervals.

Sudden and complete emptying of the dilated bladder also results in *acute renal congestion*, and if the kidneys are previously affected, medically or surgically, and are barely able to excrete the amount of urea necessary for the continuance of life, such a congestion might bring on a serious attack of uræmia, which would prove fatal, or an acute nephritis, with the same results.

Uræmia as a complication of prostatic hypertrophy may be due to acute renal congestion, to acute nephritis, or to an advanced stage of compression and suppuration of the kidney, such as exists in hydronephrosis, pyonephrosis, or pyelonephritis, or to chronic interstitial nephritis. In other words, uræmia occurs whenever the functions of the kidney are so disturbed that sufficient urinary constituents cannot be thrown off and the patient dies of toxæmia. Suppression is a frequent forerunner of uræmia, although it must be remembered that we should judge the working force of the kidney not only by the amount of urine passed, but also by the percentage of urea it contains.

The clinical signs of uræmia vary considerably, both in severity and in rapidity of onset. There may be said to be two types of uræmia, the acute and the chronic, distinguished according to the intensity and duration of the symptoms. In the first the symptoms are usually headache, somnolence, mental languor, perhaps occasional nausea, vomiting, diarrhœa, spots before the eyes, interference with the sight, dry skin, sometimes twitchings, and mild delirium. Then there may follow the uræmic convulsions, which are characteristic and resemble epileptic attacks, in which case the face becomes blue, there is froth at the mouth, the pupils are widely dilated and scarcely respond to light, and the pulse is weak and rapid during the attack, but before it is tense and slow. The breathing is accelerated and sometimes difficult. The convulsions are followed by coma, which may last for a number of hours and be followed by re-

peated attacks of convulsions. In some cases there is violent delirium together with other evidences of psychic disturbances. As a rule, the temperature rises during the attack, and sometimes there is a marked rise before death. The prognosis is not always absolutely unfavorable, and even after a number of hours in the uræmic state patients have recovered. These symptoms are not always present, and in the great majority of cases only a few of them exist.

The treatment consists in stimulating the activity of the kidney in a cautious manner by diuretics and large quantities of fluids, and in increasing the activity of all the channels of elimination by cathartics and diaphoretics (hot pack, hot drinks, etc.), and by supplying the loss in water by means of high rectal injections of salt solution or water given by the mouth. As diuretics, we may use acetate or citrate of potassium, sweet spirits of nitre, *Triticum repens*, digitalis if the heart's action is bad, or strychnine; nitroglycerin if there is arteriosclerosis; pilocarpine to produce diaphoresis; cupping over the kidneys will also sometimes stimulate them. We should be on our guard in cases of prostatitis who pass large quantities of urine with low specific gravity and have a rapid pulse.

If the patient with prostatic hypertrophy suffers to such a degree that he is not relieved by the use of the catheter and by the treatment which has been described in connection with catheter life, he must seek more radical treatment. The conditions which drive one to adopt such a course are usually vesical tenesmus, attacks of urethral fever, and recurrent epididymitis. When the patient feels that life is no longer worth living with the degree of suffering which he is enduring, he will often lean toward operative procedures, even if he knows that all such are dangerous. Of these operative methods, there are but two which are looked upon with favor today, and no prostatic should think of submitting to one of these until he has first been broken into catheter life. The two operations which may be performed if conservative treatment fails are prostatectomy and prostaticotomy. The former is enucleation of the prostate, the latter the Bottini operation.

If the prostate is large and indurated, and has the feel of an apple or an orange on rectal palpation, and if the kidneys are in good condition, then prostatectomy by the perineal method or by the suprapubic route should be performed. If the lateral lobes are principally involved, the perineal method is to be preferred; if the posterior lobe is chiefly affected, the vesical method is to be used. It may be said that the larger a prostate is the better fitted it is for a prostatectomy. If the patient is old and his resisting powers are diminished, and if the prostate feels small on rectal palpation, although there is a considerable impediment in the posterior urethra, then the Bottini operation, or galvanocautic prostaticotomy, is indicated.

Miscellany.

Death Rate of Santiago de Cuba.—The vital statistics of Santiago de Cuba for January, 1901, have been received through the courtesy of First Lieutenant Ira A. Shimer, A. S., U. S. A., acting chief surgeon and president of the board of health. They show the number of deaths for the month to have been 80, or 22.33 per 1,000. There were no cases of yellow fever, only one of small-pox, and twelve of diphtheria.

Teething at Eighty-five.—Cases of teething in old age, though by no means unknown, are not altogether common. A Trenton, N. J., woman, eighty-five years of age, having suffered for some months from pains in the jaws, has now grown two fine new teeth. But few of her second set are missing, and those that are present are said to be sound.

The Late Dr. William Pepper furnishes the subject for a glowing eulogy from the pen of Francis Newton Thorpe, formerly professor of American constitutional history in the University of Pennsylvania, in a recent number of the *Century Magazine*, under the suggestive title of A Remarkable American. The author, in speaking of his success in raising funds for the University of Pennsylvania, says: "He levied tribute right and left, on all sorts and conditions of men, and acted withal in a strikingly bold and irresistible way. After some thirty years of such action his public account stood something like this: Institutions founded: The University Hospital, the Commercial Museums, and the Philadelphia Free Library. Institutions reorganized and recreated: The University of Pennsylvania. Public reforms: The improvement of the city's water supply, and an entire change in the attitude of the public mind toward education and the ideals of life. To carry out these plans, Dr. Pepper raised above ten million dollars and secured about a hundred acres of land from the municipality, lying near the heart of Philadelphia. To the execution of this task he gave the service of one of the most acute and at the same time most practical minds ever vouchsafed to man. To this service of his genius he added the personal gift of nearly half a million dollars, which he earned in the practice of an exacting profession. It may be doubted whether any other American has run a like career."

Registration Essential to the Recovery of Fees.—A case of considerable interest has recently been decided by the appellate division of the New York Supreme Court in Brooklyn.

A physician named Michele Accetta had brought suit in the Municipal Court of the City of New York, Borough of Brooklyn, against Teresa Zupa, to recover for professional services rendered the defendant, and had received a judgment for \$100.

The answer of the defendant denied that the plaintiff was duly qualified, registered, and authorized to practise medicine as a physician in the county of Kings, and appealed from the judgment rendered against her.

The plaintiff proved that he was admitted to practise; he had graduated in the University of Naples, and had passed an examination in the University of the State of New York, and was licensed by the regents of the university in 1896, and had practised medicine since that time. The defendant then offered in evidence the register of physicians and surgeons of Kings county, for the purpose of showing that at the time of the rendering of

the services in question Accetta was not a registered or licensed physician in Kings county. This proof the trial justice refused to receive, saying that it made no difference whether the plaintiff was registered or not, and that the registry of physicians was only a police measure and did not affect a physician who was actually practising.

The appellate division, in reversing the judgment of the trial court, said: "The court erred in holding that the registry was not essential to recovery. The Public Health Law (laws of 1893, chap. 661, sec. 140) provides that no person shall practise medicine 'unless previously registered and legally authorized or unless licensed by the regents.' Section 149 provides that the license shall be registered in a book kept in the county clerk's office. Section 153 provides that any person who violates the above provisions shall be guilty of a misdemeanor and subject to fine or imprisonment. * * * It is a settled principle that one cannot recover compensation for doing an act to do which is forbidden by law and is a misdemeanor. The contrary rule would make an absurdity. It would permit one to hire another to commit a misdemeanor, and would compel the payment of the contract price for doing what the law forbids. Whether this statute is wise or not we cannot examine. It is enacted in the interest of the health of the public, to prevent incompetent persons from practising as physicians. We must give effect to it. And we cannot permit a recovery of compensation for doing an act which the statute declares to be a misdemeanor." The case is reported at length in 54, Appellate Division Reports, page 33.

Mosquito-born Malarial Infection in an Infant.—Dr. J. C. Graham, of Deli, Sumatra, writes to the *Journal of Tropical Medicine* for January 1st that an infant three weeks old greatly alarmed its parents by suddenly developing a rise of temperature that could not be accounted for by any of the usual causes. In response to the question, the parents replied that the child was usually well looked after to prevent mosquito bites but that ten days previously the native servant had carelessly forgotten to close the mosquito-curtains at night with the result that the child was simply covered with mosquito bites the following morning. The irritation caused by these soon passed off and the incident was forgotten. Dr. Graham examined the blood of the infant and found the malarial parasite. The fever yielded readily to quinine inunction.

A Greek Fraternity and Dr. Achilles Rose.—On January 7th the members of the Greek Christian Union "Equality," in Lemisso Cyprus, on the motion of Mr. Christodoulos S. Chourmouzios, nominated Dr. Achilles Rose, of New York, an honorary member of their union in recognition of their gratefulness for his efforts to promote the use of Greek as an international language among scholars, and as an expression of thanks for his philhellenic sentiments which had been so vigorously manifested during the critical periods of the Greek nation. They begged him not to cease to show his affection for the Greek language and nation, which still required all the support of their friends; for that the English administration in Cyprus had several times plotted against the Greek language, and had tried to force upon the inhabitants the use of English, on which account they wished him to express with his well-known vigor of speech the protest of the islanders and of all civilized people. A diploma of membership has been forwarded to Dr. Rose.

Original Communications.

BLOOD IN THE URINE AS A SYMPTOM, AND THE DIAGNOSIS OF ITS SOURCE.*

By JOSEPH WIENER, JR., M. D.,
NEW YORK,

ADJUNCT ATTENDING SURGEON, MOUNT SINAI HOSPITAL.

THE introduction of the cystoscope, the ureteral catheter, the Harris segregator, and similar instruments, together with the improvements in their construction, has of late years very much cleared up what formerly was an obscure field in medicine and surgery.

But in spite of the enormous stride forward in the diagnosis, and consequently of the treatment, of the diseases of the urinary tract, which the introduction of these instruments allows, the field is not yet as clear as in some other branches of surgery. The cause for this is not far to seek. The urinary organs are, for the most part, deeply placed in the body. The ordinary methods of examination, inspection, palpation, percussion, and auscultation are in very many cases of urinary disease of only negative value. We are thus compelled to seek other means to aid us in arriving at a diagnosis.

Unquestionably, the instruments which enable us to examine with the eye the prostate gland, the interior of the bladder, and the mouths of the ureters, are of enormous value. In many cases we can, from the cystoscopic picture alone, immediately make a positive diagnosis of the source of the blood in the urine. In some cases, likewise, the introduction of the ureteral catheter will tell us from which kidney the blood is flowing.

However, although cystoscopy is an easy and harmless procedure in most cases, yet there are numerous conditions which make it impracticable. I will mention only stricture of the urethra, the tendency to urethral sepsis, and profuse hæmorrhage from the prostate or bladder. Moreover, a patient may bleed once from his kidney or ureter, and there may not be a return of the hæmorrhage for weeks or months. Obviously, we cannot let such a patient wait until the hæmorrhage recurs before we make a diagnosis. Regarding the use of the ureteral catheter, it must be said that the procedure is not so easy, nor yet so harmless, as cystoscopy; neither are the results in all cases so satisfactory.

But the cystoscope and the ureteral catheter are not the only means at our disposal for diagnosing the source of blood in the urine. Furthermore, they should be employed only after we have exhausted all other methods that we possess for arriving at a correct diagnosis.

What these other methods are, how we can employ them, and in how far they are of value, these are the questions which this paper will attempt to elucidate.

*Read before the Harlem Medical Association, December 10, 1900.

When a patient with hæmaturia presents himself to us, we have two problems to solve:

1st. From what part of the urinary tract is the blood flowing?

2d. What causes it?

The diagnosis may be made from:

1. The history.
2. The examination of the urine.
3. The examination of all the organs.

1. THE HISTORY.—The *family history* may elucidate the tendency to tuberculosis, or to the uric-acid diathesis. The *previous history* of the patient may include a gonorrhœal attack, lues, typhoid fever, or one of the exanthemata. What changes may be produced in the bladder or kidney by these diseases need not be dilated upon at this time. The *age* of the patient is of importance. In early life we may find stone in the bladder, tuberculosis of the prostate or of the bladder, some of the sequelæ of gonorrhœa, sarcoma of the kidney, or a kidney lesion following one of the exanthemata. In adult life we find urethral stricture and its results, stone in bladder or kidney, and new growths of bladder and kidney. In old age we expect to find an enlarged prostate, or a stone in the bladder, sometimes a cancer of the bladder. The *time at which the blood appears in the stream* of urine should be most carefully ascertained. It is often of value in arriving at a correct diagnosis. Blood which issues from the urethra between the acts of micturition is almost certain to denote a bleeding from the urethra. Fluid blood appearing at the beginning of the stream is derived from the prostate or deep urethra. If a large amount of blood is lost from the prostate, however, it may flow back into the bladder and become intimately mixed with the urine. If a clot appears at the beginning of the stream, it is of urethral, prostatic, or vesical origin. The same is true of blood which appears at the end, or toward the end, of clear urination. In hæmorrhage from the kidney or ureter, the blood is generally intimately mixed with the urine. In a lesion at the neck of the bladder, the hæmorrhage is not limited to the beginning of the stream, but it is also seen at the end (being the bleeding that has taken place during the act of micturition). In tumor of the bladder and in vesical calculus, the hæmorrhage is most profuse at the end of the stream.

The *frequency and duration of the attacks* should also be noted. In renal hæmaturia the blood often appears suddenly, and just as suddenly disappears. After a short interval a long, thin clot may appear, followed again by profuse hæmaturia. In cases of movable kidney and of renal stone, the hæmorrhage likewise appears and disappears suddenly. If the attacks have been of long standing, the probability is that the disease is not malignant.

The *effects of exercise or of complete rest* in the course of an attack should be ascertained from the history. In bladder tuberculosis, there is a sudden appearance of bright blood, which is not influenced by rest.

Hæmorrhage due to stone in the prostate, bladder, or kidney is generally more or less relieved by rest. The same is true of hæmorrhage from a movable kidney. If, on the other hand, the bleeding persists in spite of prolonged rest, more especially if the hæmorrhage is more profuse at night, then a new growth is to be suspected (tuberculosis, sarcoma, carcinoma).

2. THE EXAMINATION OF THE URINE.—This includes macroscopic, chemical, and microscopic examinations.

Macroscopically, we can observe the size and shape of the clots, and the precipitate of blood formed on standing. Long or short, thin clots are almost certain to denote renal hæmorrhage. The clots are casts of the ureter; when they are formed, the bleeding may cease entirely, and recur with the passage of the clot. Long, thick clots indicate urethral hæmorrhage; the clot is washed away by the stream of urine.

Regarding the precipitate of blood formed from the urine on standing, it may be said that, in hæmorrhage from the kidney, the blood is so intimately mixed with the urine that, even after long standing, there is very little precipitate of blood, the urine remaining deeply tinged. If the hæmorrhage is from the substance of the kidney, this is even more true than if it is from the pelvis of the kidney. In hæmorrhage from the bladder, prostate, or urethra, the blood is readily precipitated from the urine, and the supernatant fluid is only slightly tinged, or not at all.

Chemically, there is one examination of importance; its significance has been especially dwelt upon by David Newman, of Glasgow. I refer to the estimation of the percentage of hæmoglobin, and the comparison of it with the percentage of albumin in the urine. Naturally, urine that contains blood contains albumin; but the relative proportion existing between the red blood cells and the serum is dependent upon whether or not the hæmaturia is associated with inflammation. If, for instance, there is an acute nephritis complicating some lesion causing hæmaturia, considerable albumin will be found in the urine independently of the hæmorrhage. The ratio between the quantity of hæmoglobin and the amount of albumin in the urine will thus give us a clew in diagnosing the cause of the hæmorrhage. If the ratio of albumin to hæmoglobin is about as 1 to 16, then we may infer that the albumin is entirely accounted for by the presence of blood. If the amount of albumin is considerably increased beyond the proportion of 1 to 16, then we may infer that we have to deal with an albuminuria as well as with a hæmaturia, and that in all probability the hæmorrhage is of renal origin.

Microscopically, we determine the size, shape, and color of the red blood cells, and the presence of other deposits besides blood cells. The careful examination of the red blood cells may aid us in determining the source of the hæmorrhage. Gumprecht was the first to point out the significance of the fragmentation of the red

blood cells in hæmorrhage of renal origin. The cell stretches out amoeba-like processes, so that the whole cell assumes the shape of a bottle, a club, a cross, or some similar shape. The processes thus stretched out contract into hæmoglobin-containing spheres, which either remain in connection with the mother cell, separated by a partition wall or hanging by a thread, or they tear themselves loose entirely from the mother cell. The influences which bring about these changes are manifold. Max Schultze has drawn attention to the fact that this fragmentation took place most readily if the blood is warmed to from 50° to 52° C. Arndt found that it took place even at 40° C. That the fragmentation may take place even at still lower temperatures, 26° to 29° C., if kept up for some hours, was discovered by Maragliano. Gumprecht noticed in examining urine in twenty-three cases of nephritis, that many of the red blood cells in the urine showed fragmentation, but that in cases where the blood came from the bladder these changes were not present. The probable explanation is that the blood extravasated in the kidney comes in contact with the renal epithelium, which is saturated with urea, and in consequence of this contact a certain amount of fragmentation takes place. In bladder hæmorrhage this is naturally absent. That neither the acidity of the urine in the kidney is the cause of the fragmentation, nor the alkalinity of the urine in cystitis the cause of its absence, is proved by the fact that fragmentation does take place in alkaline urine. However, it must be remembered that some fragmentation may take place on the microscope slide as an *artifact*. Hence the finding of a few red blood cells that show this change is of no value. But if many cells (up to several per cent.) show it, then the hæmorrhage is of renal origin. In bladder tumors, however, when the hæmorrhage is profuse, the clotting of the blood alone will cause fragmentation. In large renal hæmorrhage, only a small amount of blood can come in contact with the renal epithelium, and hence the fragmentation will not be so evident. It is in the small hæmorrhages, whether from the kidney or from some other part of the urinary tract, that the presence or absence of fragmentation of the red blood cells is a valuable sign.

Aside from this morphological change, there is almost always in renal hæmorrhage, as was pointed out by Gerhardt, a chemical change in the hæmoglobin, which is readily recognized by the microscope. In contrast to the unchanged greenish-yellow color and biconcave form of the red cells in hæmorrhage from the pelvis of the kidney, ureter, or bladder, we find the red cells in renal hæmorrhage at times indeed round, but as a rule somewhat smaller than normal, more spherical, and no longer biconcave; in color they are distinctly brownish-yellow or leather-yellow, some of them more or less decolorized. This change in form and color is seen in the single free red blood cells, as well as in those that are rolled together into cylinders. The same brownish-yellow color is seen

nearly all the organized products of the urinary sediment, cells from the kidney, leucocytes, casts, and bladder cells, of course in different degrees of intensity; the most marked pigmentation is seen in the kidney epithelium. The microscope will likewise aid us by showing the presence in the urine, besides blood cells, of pus, mucus, epithelial cells, tuberculous material, portions of tumors and micro-organisms.

3. THE EXAMINATION OF ALL THE ORGANS.—Every organ in the body should be carefully examined in a case of hæmaturia. A severe cardiac lesion will lead us to suspect a complicating kidney lesion. A tuberculous affection of the lung, of a bone, a joint, or glands, will draw our attention to a possible tuberculosis of some portion of the urinary tract. Enlargement of the epididymis or seminal vesicles will lead us to look for secondary disease of the bladder. A large spleen will make us think of malarial hæmoglobinuria.

The chief characteristics of hæmorrhage from the various portions of the urinary tract are:

1. *Hæmorrhage from the Urethra.*—If the blood comes from the urethra anterior to the compressor urethræ muscle, it will exude from the meatus independently of urination. If the blood comes from the urethra posterior to the muscle, it will flow into the bladder. In general, blood at the beginning of the stream or independent of the stream, and the presence of long, thick clots, are characteristic.

2. *Hæmorrhage from the Prostate.*—Blood appears chiefly at the beginning or at the end, or toward the end of the stream. If the hæmorrhage is severe, the blood flows into the bladder and mixes with the urine.

3. *Hæmorrhage from the Bladder.*—The blood is mainly seen at the end, or toward the end of the stream. The urine is mixed with considerable mucus and is bright red in color, unless it has been long pent up in the bladder. Large clots in the urine generally denote bladder hæmorrhage.

4. *Hæmorrhage from the Kidney.*—The blood is generally intimately mixed with the urine, to which it imparts a brownish-red or brown color, except where the hæmorrhage is profuse or rapid. The hæmorrhage may suddenly cease and then suddenly recur, preceded by the passage of a long, thin clot. The red blood cells do not precipitate entirely from the urine even after long standing. The red cells are altered in size, shape, and color, and often show the phenomenon of fragmentation.

After having discovered in what organ the hæmorrhage has its origin, we have next to determine what causes it.

1. *Urethral Hæmorrhage.*—The chief causes are stricture and traumatism. The traumatism may be from without (a fall or a blow), or from within the urethra (catheter, sound). Hæmorrhage in cases of stricture may come from the seat of the stricture, or from a false passage.

2. *Prostatic Hæmorrhage.*—The chief causes are en-

largement, stone, and new growth. In some cases the hæmorrhage emanates from varicose veins in the prostate. The age of the patient, the onset and duration of the symptoms, are important aids in diagnosis. Rectal and bimanual examinations are of great value.

3. *Bladder Hæmorrhage.*—The principal causative factors are stone, tuberculosis, benign and malignant new growths. We have various methods of examination which will assist us in making a diagnosis; to wit, catheter, sound, microscope, rectal and bimanual examination. The diagnosis between stone and tuberculosis, we are often called upon to make. The following table will be found useful:

VESICAL TUBERCULOSIS.	VESICAL CALCULUS.
1. Tuberculous family history.	1. Gouty or rheumatic family history.
2. Most frequent between 16 and 25 years.	2. Most frequent in adult life.
3. Urine very light, odorless, feebly acid or neutral, sometimes containing tubercle bacilli.	3. Urine turbid, often offensive, mucus and pus, urates, oxalates or phosphates.
4. Stream often arrested voluntarily on account of pain.	4. Stream arrested involuntarily.
5. Marked irritability of bladder at night.	5. Irritability only diurnal.
6. Sudden appearance of bright hæmorrhage, not influenced by rest.	6. Hæmorrhage ceases on rest.
7. Usually a few drops at end of stream, accompanied by straining.	7. Hæmorrhage most profuse at end of micturition.
8. Distinct periods of quiescence, uninfluenced by violent exertion.	8. No distinct periods of quiescence, except on rest.
9. Sudden relief of suprapubic pain and rapid cessation of pain in glans after emptying bladder.	9. Pain often persists after emptying the bladder.
10. Persistent post-scrotal pain.	10. Absent.
11. Involvement of epididymis, prostate, or some other organ.	11. Absent.

The diagnosis between benign and malignant new growths of the bladder is often difficult to make. Moreover, some growths are on the border line of malignancy. Frequently a benign growth (papilloma) degenerates into a malignant one (carcinoma). The age of the patient and the duration of the symptoms are important data. A cystitis will seldom or never supervene on a new growth unless an instrument (catheter, sound) has been introduced into the bladder. If a cystitis develops without such an interference, the probability is that the process is a tuberculous one. Primary new growths of the bladder are three times as common in men as in women. In seventy-five per cent. of cases of vesical cancer, and in over ninety per cent. of the benign bladder tumors, hæmaturia is the first symptom. This is quite characteristic, particularly if the hæmorrhage takes place without any discoverable cause. In cases of vesical calculus the hæmorrhage can often be referred to exercise or to examinations of the bladder. In vesical tuberculosis we generally have other signs and symptoms besides the hæmorrhage. In new growths of the bladder, on the other hand, the hæmorrhage is generally the first symptom in an otherwise healthy subject, and the bleeding is often profuse. This sudden profuse hæmorrhage generally ceases just as abruptly as it set in.

In benign growths there is often a history of long duration, and the onset of the disease is generally insidious. The hæmorrhage recurs at longer or shorter intervals, sometimes not for many months, and it is distinctly intermittent even in the advanced stages, but it is rarely profuse or arterial in character. In the male, coition will bring on or increase the hæmorrhage. The hæmorrhage is generally relieved by rest. At some time in the course of the disease it is of a distinctly vesical type—*i. e.*, there is blood at the end of a clear urination.

In malignant growths the hæmorrhage at the onset may be slight, but more often it is profuse. At first it is intermittent, depending on exertion, but it soon becomes more or less persistent, and becomes offensive from the presence of mucopus and *débris*.

Among other symptoms called forth by a tumor of the bladder are pain and frequent micturition. In benign growths these symptoms are frequently absent. Another symptom, which is of importance only in the absence of stricture or enlarged prostate, is the inability of the bladder to empty itself completely (residual urine). Sometimes particles of tumor are voided in the urine and can be recognized microscopically. Examination under chloroform may be of value. It may be carried out by a finger in the rectum and a catheter in the bladder. The finger in the rectum feels the bladder wall against the catheter. The careful examination with the catheter or sound may show the presence of rough areas on the vesical mucous membrane. According to Guyon, a catheter should be introduced into the bladder and the urine withdrawn. If toward the end of the catheterism bloody urine is withdrawn, there is probably a new growth in the bladder.

4. *Renal Hæmorrhage*.—The commonest causes are stone, tuberculosis, tumor, and injury. In diagnosticating the source of the hæmorrhage, the "*cathétérisme en deux temps*" of the French is sometimes of value. Introduce a catheter, empty the bladder, and keep the specimen for examination. Wash out the bladder, empty it, and keep the last few drops of fluid in a second glass. Wash out the bladder again, empty it, and allow the catheter to remain while bimanual pressure is made over one kidney and along its ureter; collect this fluid in a third glass, and that obtained from the opposite side in a similar manner in a fourth glass.

The diagnosis between renal calculus and renal tuberculosis is, in the initial stages, perhaps the most difficult we are called upon to make. Newman calls attention to the fact that, as it is not uncommon to meet cases of profuse and frequent hæmoptysis long prior to the development of any recognizable physical signs of pulmonary tuberculosis, so also in renal tuberculosis hæmaturia may be present as a premonitory symptom. But while hæmoptysis has been looked upon as a valuable danger signal of pulmonary tuberculosis, hæmaturia has not been looked upon in a similar light; although in

some cases it undoubtedly carries with it a similar warning. Polyuria, due to the presence of the growth, may be the first symptom, even antedating the aching in the loin. Before destructive processes commence within the renal pelvis, or the substance of the kidney, traces of albumin and small quantities of blood may be found; but, when the tuberculous deposit has begun to break down and to become evacuated into the ureter, we find many tubercle bacilli in the urine and considerable albumin, along with pus and *débris* of renal tissue. The albuminuria differs from that of Bright's disease in that the urine is not clear, but is cloudy, and contains much mucus, but no casts. Profuse hæmorrhage occurs only rarely in renal tuberculosis. As the disease advances, the urine generally becomes more and more foul. The hæmaturia is often absent for long periods, is not increased by exercise, and is rarely so severe as in cases of renal stone. In the early stage, according to Newman, the amount of albumin is generally in excess of that accounted for by the blood; and in the later stages, when pus appears in considerable quantity, the pus and blood are not so rapidly or so completely precipitated from the urine as in calculous pyelitis. In the initial stage, however, renal tuberculosis has many points in common with renal calculus. There is the same pain in the loin, which may radiate to the groin, testis, thigh, or knee; the same recurrent severe colic; the blood and pus in the urine; the frequent micturition, and the same pain in the penis after emptying the bladder.

In hæmaturia due to renal calculus, the hæmorrhage is usually small in amount, and generally recurs at short intervals. The hæmorrhage bears no close relation to the pain, or to the other symptoms; it is generally increased by exercise and diminished by rest. This is an important point of difference from renal tuberculosis. As there is usually no nephritis associated with the presence of a stone in the pelvis of the kidney (at least in the earlier stages of the disease), the quantity of albumin is fully explained by the presence of the blood. When the blood is absent from the urine, there is likewise no albumin present. The blood is thoroughly mixed with the urine, but not so thoroughly as when the hæmorrhage is from the renal parenchyma. As a result, after standing a few hours, the red blood cells will all be precipitated, leaving the supernatant fluid clear. Pus is found in the urine only after the stone has produced inflammatory changes. A calculus obstructing one ureter may reflexly cause inhibition of the other kidney with complete anuria. Irritation of the bladder by fragments of stone, and consequent frequent micturition, are common. Gastric disturbances are likewise often present.

In the advanced stages of both renal stone and renal tuberculosis, there is a pyelitis present. If the pyelitis is of tuberculous origin it will in time spread to the ureter or bladder, while in the case of a calculous pyelitis it will not.

PRIMARY RENAL TUBERCULOSIS.

1. *Family history* of tuberculosis.
2. *Age*, between 20 and 40 years.
3. *Personal history*: Perhaps tuberculous joints, bones, glands, or lungs.
4. *Symptoms, onset*: Polyuria of a murky type, vague lumbar pain or a sudden chill and severe pain in one kidney, but rarely a colic. Frequency of urination *at night* in the early stages.
5. *Colics* appear later, are usually less severe, do not usually retract the testicle, and are preceded by bright blood, if due to ulceration.
6. *Hæmaturia* slight in amount and *not* influenced by rest.
7. *Urine* cloudy at outset from admixture of mucus and pus. Acid, low specific gravity, light color, depositing a thin layer of pus with streaks of blood. Albumin appears early, and is generally in excess of that accounted for by the blood.
8. *Urine in advanced stage*. Pus and blood not so rapidly or so completely precipitated from the urine as in calculous pyelitis. The deposit contains small caseous masses, mixed with renal debris. On standing, it is not all precipitated, but some remains suspended and makes urine appear cloudy.
9. *Tubercle bacilli* may be found after repeated examinations; or inoculation of urinary deposit into animals induces a tuberculous inflammation.
10. *General condition* of patient, even in early stages, is poor.
11. *Inflammation* may spread to ureter, bladder, seminal vesicles and prostate.

RENAL CALCULUS.

1. Family history good, or of uric-acid diathesis.
2. Age, about 40 years.
3. Negative, except perhaps passage of sand or gravel; testicular neuralgia.
4. Vague lumbar pain or a sudden colic. Small quantities of urine passed often during day, but *not at night*.
5. More or less severe according to size, location and composition of stone. They may be followed by bleeding. Pain radiates to peritonæum, testicle, or down the thigh. It may be referred entirely to the opposite side.
6. More marked, intermittent, *dependent on exercise*.
7. Clear at outset, containing signs of calculus in the shape of crystals. Not more albumin than is accounted for by the presence of blood.
8. When urine is passed, blood and pus are intimately mixed with it, but if +urine is allowed to stand a few hours the blood cells are precipitated and the supernatant urine is clear.
9. Negative.
10. Patient often in excellent general health in early stages.
11. Inflammation does not spread to other organs.

Renal Tumor.—Very often hæmaturia is the first symptom, and it is generally profuse, appearing without any preceding pain. Renal colic may, however, arise from the temporary impaction of a clot in the ureter. There may be blood casts of the pelvis of the kidney and ureter. The hæmorrhage is most frequent at night, when the patient is in the recumbent posture. Sometimes, though not often, pieces of new growth may be recognized in the urine. In most cases a tumor can readily be felt.

Among the rare causes of renal hæmorrhage may be mentioned hæmophilia, movable kidney, hydronephrosis, parasites (filaria and *Bilharzia hæmatobia*), torsion of renal vessels, cystic degeneration of kidney, and mechanical causes, such as pregnancy. Of course, as is well known, hæmaturia takes place in some cases of acute nephritis and occasionally in chronic nephritis.

Errors in the diagnosis of hæmaturia from the appearance of the urine may arise under various conditions:

	Age.	Symptoms.	Frequency of Urination.	Pain.	Blood.	Influence of Rest on Amount of Blood in Urine.	Time at which Blood Appears in the Stream.	Condition of other Organs.
PROSTATE.....	Middle to old.	Absent in early stages.	Increased, diurnal and nocturnal.	Usually none.	Clot at beginning. Blood at end, or towards end, of clear urination.	Relieved, especially if due to stone.	Beginning or end. If profuse, blood is mixed with entire stream.	Cystitis; later, pyelonephritis.
STONE IN BLADDER.....	Usually childhood and adult.	Urination involuntarily arrested. Those of a cystitis.	Markedly increased; diurnal; relieved by rest.	Glans pain even after urination. No post-scrotal pain.	Most profuse at end quite constant.	Very much relieved by rest.	Completely precipitated on standing.	Normal.
TUBERCULOSIS OF BLADDER.....	Early life.	Urination voluntarily arrested.	Diurnal and nocturnal; not relieved by rest.	Pain in glans ceases after urination. Persistent post-scrotal pain.	Sudden appearance of bright blood. Transitory. Usually few drops at end, with straining.	Not influenced by rest.	Generally at end.	Prostate, seminal vesicles, and epididymis often involved.
TUMOR OF BLADDER.....	Advanced.	Generally absent except in advanced stages.	Often not increased.	Generally absent.	Intermittent. Often nocturnal; often profuse.	Not influenced by rest.	Completely precipitated on standing.	Generally normal.
STONE IN KIDNEY.....	Adult, usually about 40 years.	General condition good; later, pyelitis.	If increased, relieved by rest; diurnal.	Severe repeated colics.	More than in tuberculous; rarely profuse.	Relieved by rest; increased by exercise.	May appear and disappear suddenly. Intimately mixed. Almost completely precipitated on standing.	Pyelitis in later stages.
TUBERCULOUS KIDNEY.....	Young adult, to 40 years.	General condition poor; anemia; later, often pyelitis.	Marked diurnal and nocturnal.	Severe pain; rarely severe colic.	Often absent for long periods. Usually slight amount.	Not influenced by rest or by exercise.	Very intimately mixed. Not completely precipitated on standing.	Pyelitis spreading to ureter and bladder.
TUMOR OF KIDNEY.....	Advanced (carcinoma); early (sarcoma).	Those of an abdominal tumor.	Not markedly increased.	Colic due to clot in ureter.	Profuse; often more at night.	Not relieved by rest.	Very intimately mixed. Not completely precipitated on standing.	Generally normal.

1. Hæmoglobinuria.
2. Drugs which cause blood in the urine, or bloody-looking urine.

}	<i>Potassium chlorate,</i> <i>Turpentine,</i> <i>Cantharides,</i> <i>Carbolic acid,</i> <i>Sulphonal,</i>	}	Spectroscopic examination in a doubtful case.
---	---	---	---
3. Food.—Rhubarb, strawberries, and gooseberries cause hæmaturia in some subjects.
4. Menstrual blood often gets into the urine, and may cause an erroneous diagnosis to be made.

Hæmoglobinuria may be readily recognized by the color of the urine together with the absence of red and white blood cells. In a doubtful case the spectroscope would show the characteristic two dark bands between the Fraunhofer lines D and E. Hæmoglobinuria is found in malaria, typhoid, scarlatina, and lues. Some cases have been reported in which intense cold or severe exertion was believed to be the ætiological factor.

In conclusion, I would say that I have attempted to show how, in many cases of hæmaturia, the diagnosis can be made without the use of any complicated apparatus. We are perhaps a little too prone in this age of medical and surgical progress to lay aside old methods (many of which are of value) for new ones, which, though giving promise of great results, too often disappoint in the end.

That the diagnosis of the source of blood in the urine cannot in many cases be made without the use of the cystoscope, goes without saying. There will always be doubtful cases of hæmaturia, some of which even the cystoscope, ureteral catheter, and Harris's segregator will not be able to clear up. But, if the diagnosis can be made without these instruments (and in many cases, by the conscientious application of the methods above enumerated, it can be so made), then we say it is better for the doctor and better for the patient. Let us attempt, in every case of hæmaturia, to exhaust all the older methods at our disposal before we fall back upon the new ones. Very often we shall be able, by painstaking systematic study of the case after the cystoscope and ureteral catheter have left us in the lurch, to arrive at a correct diagnosis.

The table accompanying this paper is intended as an epitome of what has been said above, and is not by any means intended as a complete exposition of the subject matter:

65 WEST EIGHTY-FIFTH STREET.

THE SPECIFIC TREATMENT OF ACUTE DYSENTERY.*

BY WILLIAM J. CRUIKSHANK, M. D.,

BROOKLYN, N. Y.

DYSENTERY is a disease of antiquity, concerning which much has been written; it was recognized by Hippocrates, who clearly distinguished it from diarrhœa, and pointed out its gravity. Herodotus mentions it, and an accurate clinical picture of the disease is drawn by Celsus. Galen wrote of two kinds of dysentery, one coming from disease of the liver, which he named hepatic dysentery, and the other resulting from ulceration of the mucous membrane of the intestine. Since Galen's time the disease has occupied the attention of

many observers, and during recent years the bacteriology of the subject has been earnestly considered by such men as Lambl, Blanchard, Bertrand, Lösch, Kartulis, Harris, Koch, Councilman, La Fleur, Shiga, Kitasato, Osler, and a host of others. "There are few subjects in medicine," says Professor Flexner, "that have attracted more attention than dysentery. Its history dates from the earliest written records, and its ravages, unlike those of many of the pestilential diseases, have continued practically unaltered to the present day." Many contributions to the literature of dysentery have been added by clinicians, who have had the opportunity of observing the disease in tropical climates. One of the most interesting of these contributions is that of Sodr , of Rio Janeiro, which is to be found in volume xvi of the *Twentieth Century Practice of Medicine*. He defines dysentery to be an infectocontagious disease, endemic in warm countries, sporadic or epidemic in temperate regions, characterized anatomically by lesions of various organs, such as specific ulceration of the large intestine, and, clinically, by the occurrence of frequent bloody mucous or serous dejections, accompanied by tormina and tenesmus, and by more or less accentuated general symptoms. A realization of the gravity of dysentery is hardly possible without reverting to the history of its mortality. In Japan, according to Shiga, dysentery prevails annually with considerable intensity. From January to December, 1897, 90,000 persons were taken with it, 20,000 of whom died. According to the statistics of Ogata and Eldridge, which are incorporated in the very interesting paper of Professor Flexner on the *Ætiology of Tropical Dysentery*, published in the *Philadelphia Medical Journal* for September 1, 1900, there occurred in Japan, from the year 1878 to 1899, inclusive, 1,136,047 cases of dysentery, 276,309 of which were fatal, making a mortality of between twenty-four and twenty-five per cent. These statistics have been carefully tabulated and show a remarkable increase of the disease, year after year. The epidemic, which was studied bacteriologically by Ogata, says Flexner, occurred in the Province of Oita, where, in 1890, 801 cases occurred with 225 deaths; and in 1891, 8,390 cases with 2,163 deaths, an average mortality of from twenty-six to twenty-seven per cent. This epidemic had been preceded by sporadic cases in the previous winter, and in its spread showed a strikingly contagious character. A truly ubiquitous disease, says Sodr , it is not limited by latitude, and we think we can affirm without fear of denial that there is no country and no extensive district of any country from the equator to the poles, in which dysentery has not been observed. In Greenland, Northern Russia, Norway, Iceland, Sweden, Siberia, etc., its presence has been noted at different times. According to Lombard, it is one of the most widely spread diseases in Sweden, where it sometimes assumes great gravity. In the year 1857, for example, 37,000 persons were attacked with it in that country, of whom 10,000 died.

* Read before the Kings County (N. Y.) Medical Association on December 11, 1900.

Every country in Europe has paid a heavy tribute to dysentery. More or less extensive and deadly epidemics have at different times visited these countries, producing ravages similar to those of the so-called pestilential diseases. In referring to the gravity of the disease, Sodr  says that dysentery is one of the four great epidemic diseases of the world. In the tropics it destroys more lives than cholera, and has been more fatal to armies than powder and shot. The statistics of the French army illustrate the difference in the rate of mortality between temperate and intertropical regions. In France, for example, the death rate among the troops from dysentery is said to be one twentieth of the total mortality, while in Algeria it is one fifth, and in Senegal one third. In the English army at home the disease is comparatively rare, while in India and China more soldiers die from dysentery alone than from all other diseases to which they are liable in Europe. In the tropical climates the natives, as well as the foreigners, are attacked by it, and its fatality is usually great, particularly among the native population. It is asserted by Zimmerman that infants whose mothers have dysentery are born with it. According to Hirsch, the death rate recorded from dysentery in Europe has been as high as from seventy-six to eighty per cent. of the number attacked, while in epidemics occurring in temperate climates, ordinarily, the mortality is said to vary from seven to fifteen per cent. From 1841 to 1846, in the epidemics which prevailed in France, seven tenths of those attacked died. From 1836 to 1837-1838, twenty-five per cent. died; and in 1857 one out of every five died. In tropical epidemic dysentery the mortality is recorded as being from twenty to thirty per cent. Even in Hong Kong it has reached a mortality of twenty per cent. Some statistics which have been collected from the tropical countries show a mortality of from thirty-five to forty per cent., and even as high as one as from sixty to eighty per cent. has been noted. A long sojourn in endemic countries, says Sodr , will not confer immunity from dysentery. On the contrary, according to some observers, the longer the term of residence of a European in the colonies, the more predisposed he is to contract the disease. A careful investigation of the experience of soldiers situated in the tropical countries proves conclusively that there is no acclimation to dysentery. In Martinique, for example, it has been shown that more dysenterics are found among the soldiers of the garrison who have remained on the island several years than among the soldiers who go and come, staying only for a short time. This experience is concurred in by writers who have also observed the disease in India. Dysentery has proved itself a great scourge to the people of the United States. It requires only the most superficial examination of the statistics to convince one of this fact. In the article written by West on Dysentery, which is to be found in volume i of Loomis and Thompson's *Practice*, the author says, in speaking

of the disease: "It takes rank in malignancy and mortality with yellow fever, small-pox, and cholera; it is the scourge of armies, causing more sickness and death than any other disease, patients with dysentery and diarrh a rivaling the wounded in multitudes and constituting a large proportion of the discharged for disability." Pepper has said that epidemic dysentery has probably killed more soldiers than all the other diseases put together, and he gives it as his opinion that in the civil war of the United States the disease was the means of killing over 300,000. The total death rate from dysentery in the United States in the year 1850 was 20,556, or $6\frac{32}{100}$ ths per cent. of the total mortality. In 1860, 10,468, or $2\frac{65}{100}$ ths per cent. During the war of secession the disease existed to an alarming extent in both armies. According to Woodward's report, which appears in volume ii of the *Medical and Surgical History of the War of the Rebellion*, there were in the Federal army, in all, 257,071 cases of acute dysentery and 28,451 cases of chronic dysentery. With reference to these statistics Woodward says: "Probably a considerable proportion of the 182,586 cases of chronic diarrh a should also come within this category." In 1880, in the United States, out of a total death rate of 785,893, there were 10,825 deaths from dysentery. Recent official reports from the United States army and navy do not give detailed and definite accounts of the number of cases of dysentery, with its accompanying death rate, which occurred during the late war with Spain. These reports, so far as I have been able to determine, include dysentery under the head of diarrh al diseases. Flexner's reference to this point is, however, interesting. He says, in referring to the report of the surgeon-general of the United States army for 1899: "This compilation fails to give an adequate idea of the extent, severity, and mortality of dysentery in Manila. Although, unfortunately, figures are not obtainable, I am convinced, after nearly three months' residence in Manila, that the enteric diseases, of which dysentery was the most frequent and important, were the chief causes of disability and mortality among the land forces of the American armies." (Professor Flexner was one of a commission sent to Manila by the Johns Hopkins University for the purpose of studying the diseases prevailing in the Philippine Islands.)

In a personal communication from Dr. Roger S. Tracy, the registrar of vital statistics for Greater New York, he informs me that in the whole city, in the year 1898, there were 368 deaths from dysentery, 164 of this number occurring in the Borough of Brooklyn. In 1899 there occurred in the whole city 267 deaths, 111 of this number occurring in the Borough of Brooklyn. These figures are interesting, since they suggest either a great mortality or a very large number of cases occurring at our own door.

With regard to the  tiology of dysentery, there seems still to be some doubt, and much conflict of opinion pre-

walls concerning its specificity. The preponderance of evidence, however, seems to be in favor of the amœba theory. After a careful review of the bacteriology of the subject, Sodr  expresses himself as being thoroughly convinced of the amœbic ætiology of the disease, and regards the existence of the amœbæ in the contents of tropical abscess of the liver as being one of the most powerful arguments in favor of his belief. There does not seem to be any further question among bacteriologists that dysentery is produced by the introduction into the system of micro-organisms. But there seems to be considerable contention as to whether the infection is polybacterial or specific, and many conflicting opinions are expressed along these lines by eminent observers. The part of this branch of the subject which interests the clinician more particularly, however, is to know how the infection gets into the human system, thence into the intestine, there to produce the lesions of the disease. According to Councilman and La Fleur, the germ reaches the large intestine in food or drink. Sodr  expresses the opinion that the germ may also be taken in with the air; and he makes the positive statement, which seems to be borne out by equally eminent observers, "that the food may be contaminated by the hands of persons who have been in contact with dysenterics, and that in this way the disease is frequently propagated." Foquet, who made observations in Brittany, concludes that contamination by the hands is the most common mode of contagion, nurses and other persons who are in attendance upon the sick frequently handling the bread, the clothes, the table, the dishes and cooking utensils, without washing their hands. There seems to be very little doubt that in this way the disease is transmitted to different members of the same family. The theory that dysentery may be propagated by contagion is apparently established, and the following experience of Bertrand, as related by Sodr , in this connection, is very interesting: "In the course of certain epidemics of dysentery, two pharmacists made the chemical analyses of dysenteric matters. These pharmacists were not in any way engaged in the hospital where the dysenteric patients were received and treated. Their chemical operations lasted several days, and, notwithstanding that they carefully washed their hands with antiseptics at the end of each session, they were attacked by the disease." Sodr  further reports Arnold as saying that the contagion of dysentery is an illusion which is lost after a close observation in hospitals where patients with dysentery are received.

May I be permitted, now, briefly, to say a few words concerning the pathological lesions which accompany this morbid process, in so far only as they have bearing on the intelligent treatment of the disease? Pathologists all agree that all of the tunics of the large intestine may be involved in the inflammatory process, the destruction of the tissue at times extending to perforation of the peritoneal covering. In mild cases the lesions are

confined to the lower part of the large intestine, or, perhaps, to the upper part, and the anatomical changes do not pass to extensive ulceration, but I think it may be safely asserted that the characteristic lesions are found in nearly all cases. The whole of the mucous membrane of the large intestine, or any part of it, may be the seat of the disease, the inflammation sometimes extending beyond, to the lower part of the ileum. "The specificity of dysentery," says Sodr , "demonstrated by the study of the cases that proceed under its genesis, is absolutely confirmed by *post-mortem* examinations." It is true, he says, that in relation to certain details of the anatomical process the descriptions do not completely agree, but in all of the descriptions we find the specific and characteristic lesion of the disease, viz., the undermined ulcer of Councilman and La Fleur. Furthermore, "the diversions observed in *post-mortem* examinations performed by various investigators are not at all surprising when we consider the more or less important r le that micro-organisms foreign to the disease, normally inhabiting the intestine, or reaching it accidentally, play in the anatomical process of dysentery." The gangrene of the intestine, for example, which sometimes occurs, Sodr  does not regard as a true lesion of the disease, but a complication of it, and in all reasonable certainty due to foreign bacteria. Councilman and La Fleur, says Sodr , describe the process as essentially one of advancing infiltration and softening in the submucous and intermuscular structure, with subsequent necrosis of the overlying tissue. "The amœbæ reach the submucosa, producing but few lesions in the mucous membrane, and the essential changes are produced in the submucosa, the mucous membrane being attacked from below. So far as could be seen, the changes which they produce in the mucous membrane are an œdema with some fibrin formation, and, occasionally, necrosis. The œdematous tissue then softens, the mucous membrane is broken through, and the ulcer follows. On the surface of the ulcer there is always found a gelatinous substance which can be wiped away, leaving the ulcer clean. When examined fresh under the microscope, it is found to contain amœbæ, large, round, swollen cells, red corpuscles, and pus cells. These cells are also found scattered through the thickened tissues of the submucosa, being more numerous at the points where the morbid process is more advanced. They seem to be connective-tissue cells which have become free by the softening of the tissues around them. The blood-vessels always present more or less marked lesions, and are frequently thrombosed; the walls of the arteries are thickened and infiltrated with round cells. In the arteries are often found the alterations of obliterating endarteritis in a more or less marked degree; the walls of the veins are likewise infiltrated with round cells and generally regressive degenerations which facilitate their rupture." According to Harris, "an amœba may occasionally be seen in the act of penetrating the walls of the veins, part of the

body being within and part without the lumen of the vessels"; "the lymphatics are always dilated; the lesions of the mucosa at a certain distance from the ulcers are in general little accentuated; very intense hyperæmia of the tissue is noticed, particularly in the superficial layer; hypersecretion of mucus; accumulation of leucocytes, and frequently interstitial hæmorrhage."

The variety of the pathological changes described by Eldridge, Ogata, Shiga, and others, and recently by Flexner, who reports his findings in three cases occurring at Manila, is very interesting from a bacteriological point of view, but need not be considered here, because the differences do not seriously affect questions involving the gross pathology of the disease. The descriptions all show that the mucous and submucous tissues may be simultaneously involved in the pathological process, or that the submucosa may suffer independent alterations, and also that the diseased conditions may extend to all the tissues of the large intestine.

There is, in my opinion, no branch of the literature of acute dysentery more thoroughly misleading to the general practitioner than that which is devoted to the consideration of the so-called different types or varieties of the disease; and I am convinced that investigation will result in conclusions which will simplify our progress toward a uniform and specific plan of treatment. Just as the former use of vague terms and a multiplicity of words, for years, misled the medical profession in the diagnosis and treatment of inflammatory troubles of the vermiform appendix, so we have been misled here. The real truth seems to be that dysentery is one disease, and one only, and that the so-called varieties have for their foundation mainly the mistaken ideas which have prevailed regarding the ætiology and pathology of the disease. The writers of antiquity had a much more exact conception of the truth of this suggestion than did many of those who expressed later opinions; and those who, like Trousseau, remained faithful to tradition, expressed themselves along the line of what is now in this connection recognized to be the truth by advanced pathologists. Subsequent to the comparatively accurate description of true dysentery given by Celsus, medical literature became filled with accounts of many varieties of the disease, based on all sorts of erroneous ideas concerning its ætiology and morbid anatomy. To use the words of Sodr , "The clear and accurate conception of dysentery in the works of ancient authors was modified in the course of time under the influence of the ruling medical doctrines. The morbid unity so well established disappeared and was replaced by the varied forms of dysentery described and considered as different entities, without the common features of clinical and anatomical characters. The disease came to be confounded with simple diarrh a and enteritis." Thus we find Sydenham, the so-called English Hippocrates, writing on epidemics in 1680 and describing three forms of dysentery. The first he char-

acterizes by "gripes without stools," or "dry colics, sometimes accompanied with fever." The second form he describes as with "frequent and slimy motions attended with griping and usually with fever," "which," he says, "is a true bloody flux, although there may be no passage of blood from first to last." His third variety is described as having fever; bloody and mucous stools, with griping and tenesmus. And thus we read of various descriptions of the disease, including so-called "putrid dysentery," "bilious dysentery, due to putrid decomposition of the blood," "diphtheritic dysentery," "intermittent dysentery," "remittent dysentery," "scorbutic dysentery," "rheumatic dysentery," "hepatic dysentery," etc. "It is a rheumatic fever," says Stoll, when writing of the disease, "the humors of the perspiration driven in by cold." Hunter, who observed the disease in the tropics, wrote of a non-infectious variety, and did not believe the true disease contagious. "After the writing of Sydenham, Wells, and Stoll," says Sodr , "dysentery was considered independent of any intestinal lesion." One of the most common and misleading of these so-called varieties is what is described by most authors as "malarial dysentery." "Typhoid dysentery" is also spoken of, owing to the fact, no doubt, that dysentery is developed concomitantly with the various forms of malarial infection and typhoid fever. Thus we travel through a labyrinth of types and varieties of the disease until we arrive at the more recent writings of Councilman and La Fleur; and we find even these eminent investigators attempting to prove that there is a variety of independent forms of dysentery; but the words of Sodr , in pointing to the views expressed by these gentlemen, seem to me to carry conviction. He says: "Councilman and La Fleur, two careful and competent American observers, who published an excellent monograph full of original investigations on the ætiology and pathological anatomy of dysentery, endeavored to establish a distinction which I do not think entirely convenient and which appears destitute of foundation. They hold that the term dysentery embraces various affections of the intestine and describe a special form, which they call amœbic dysentery. Amœbic dysentery, they write, is a form of dysentery which ætiologically, clinically, and anatomically should be regarded as a distinct disease. *Clinically* this disease is characterized by the presence of amœbæ in the stools, which in addition present physical characters different from those seen in the stools of other forms of dysentery. Anatomically, the disease is characterized by the production of ulcers in the colon, which generally differ from those found in any other form of dysentery. The ulceration is produced by infiltration of the submucous tissue and necrosis of the overlying mucous membrane, the ulcer in consequence having the undermined form. Frequently, in addition to the ulcers there is infiltration of the submucous tissue, without ulceration. Abscess of the liver is a frequent complication, much more so than in any

other form of dysentery. And they conclude with the assertion that this is the form of dysentery which has been commonly called 'tropical dysentery.'" "At first sight," says Sodré, "we might suppose that Councilman and La Fleur considered this dysentery of the tropics as different from the dysentery observed in the temperate regions. Such is not the case, however, since these observers made their investigations far away from the tropics, and write referring to amœbic dysentery: 'The disease is widely distributed in most countries in Europe, in most parts of the United States, and in the tropics everywhere.' It would have been more logical and rational had Councilman and La Fleur, while establishing the relation of cause and effect between dysentery and the *Amœba coli*, proclaimed the specificity and unity of the disease, separating it from all forms of enteritis not proceeding from the same cause. To admit a dichotomy in the morbid process; to recognize the existence of an amœbic dysentery and another not amœbic, seems to me to be absolutely unacceptable. Dysentery is one disease and one only, whether considered from an ætiological, clinical, or anatomical point of view. Various ætiological factors, some of which are trifling even, concur efficaciously to the genesis of dysentery; they act in a secondary manner, preparing the ground and aiding the action of the dysenteric germ, without the concurrence of which the disease cannot occur, whatever the latitude in which the observation is made."

"Various clinical modalities from mild dysentery to gangrenous dysentery are observed, and sometimes simulate different diseases. Nevertheless, among the varied clinical features, common traits are always found which represent the clinical character of the disease. The same may be said in regard to the pathological anatomy. Various anatomical forms have been described, but among the lesions of different character, extension, and seat, we always find a characteristic lesion, which represents the true substratum of the disease. Just as it is not allowable to separate acute miliary tuberculosis, pneumonic tuberculosis, and chronic ulcerous tuberculosis, as constituting three special diseases; just as we may not consider atrophic beri-beri and dropsical beri-beri as two distinct diseases, although appearances may lead us to do so, in like manner there is nothing to justify the divisions of dysentery into two or more different affections from an ætiological, anatomical, and clinical point of view. *Dysentery is one disease and one only, and is always the same whether observed in the tropics as endemic and with marked tendencies to become chronic, or in temperate regions as sporadic or epidemic.*" Thus, we find this experienced observer reducing the whole subject to a simple classification which has for its principal foundation the intensity of the disease, viz., "the mild form, the medium form, and the grave form," each of which he describes according to its clinical aspect, taking always into consideration the morbid

anatomy. May we not, therefore, practically eliminate from this branch of the subject those misleading and disturbing theories of ætiological variety which have contributed much toward the development of empiricism in the treatment of this disease, and in their stead ought we not strive to build on the true foundation already established by such men as Sodré? I fully realize the fact that this simple classification is open to some criticism, but such criticism must, it appears to me, be purely technical. Even so careful and conservative a writer as Flexner, who has contributed very recently an account of his scientific experiments with the dysentery occurring among our soldiers in the Philippine Islands, expresses the opinion *that the conclusions of bacteriologists which have been the means of establishing various types of the disease may not be in keeping with the real facts*, and says: "When we recall the protean nature of other infectious diseases, among the most common of which are tuberculosis and typhoid fever, there can be no *a priori* objection to the hypothesis that the causative agent of dysentery need not necessarily vary for each of the many types of the disease that have from time to time been distinguished." And further: "The literature of dysentery is burdened with an interminable mass of appellations indicating the nature of the disorder, or the author's conception of its pathological anatomy." While Flexner does not entirely agree with those writers who, with Sodré, express the *positive* belief in a specific organism, still, his bacteriological suggestions are necessarily so incomplete as to prove nothing against the theory that dysentery is one disease, whether occurring in one place or another, and do not in any way affect the clinician in the treatment of the morbid conditions. For even if the specific ætiological factor is the *Amœba dysenteria* of Lösch, or a bacillus which has not as yet been isolated, or both, the pathological indications for a rational plan of treatment remain identical—and to a great extent disregarded.

(To be concluded.)

THE PATHOLOGY OF INTRA-UTERINE DEATH.

By NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

NEW YORK,

VISITING SURGEON, POST-GRADUATE HOSPITAL.

(Continued from page 364.)

ECTOPIC PREGNANCY.—This erratic form of pregnancy is almost always fatal to the foetus. It is somewhat remarkable that such a serious condition should be for so long a time neglected and its victims allowed to perish without any effort being made to save them. Until the marvellous advancements achieved in recent years of abdominal surgery, little or no progress was made in elucidating the pathology of this variety of pregnancy. In 1875, Parry wrote a singularly interest-

ing book upon the subject, and by his critical acumen, profound research, and beautiful diction attracted the attention of the profession to this neglected subject. True it is, that Albucasis was long before familiar with the condition, but little in a practical way was done in elucidating its ætiology or pathology until Lawson Tait grappled it to the surface with hooks of steel. After he had written his excellent monograph, describing its frequency and the methods of operation, his methods were quickly taken up and followed by other surgeons. How grudgingly merit is tendered to its rightful possessor! The withholding fame or applause from ability by the narrow-minded bickerings of narrow-minded men has seldom been more markedly exemplified than upon this identical subject. But now that the ashes of a great man have been gathered to his forefathers, we hope that other minds shall sit in judgment, that the memory of the late Robert Lawson Tait shall stand pre-eminent and proud for rescuing from the thralldom and teachings of the ancients and placing upon a firm scientific basis the subject of ectopic pregnancy.

We have long maintained, and recent events have but added to the conviction, that in order to thoroughly understand the pathology of ectopic pregnancy, it is absolutely essential to have a clear and distinct conception of certain theories of menstruation, as well as of those of normal fecundation, and here we come upon peculiarly interesting ground. They are much too long and altogether too intricate to enter into fully here; but, nevertheless, they require a few passing remarks. For this purpose we are obliged to eliminate many theories that were inculcated into our young and unsuspecting minds by our various teachers of obstetrics; theories that have been handed down from one text-book to another with unerring fidelity. With them the æstrus, or rut, of animals was considered analogous to menstruation of the human female. Their teachings in regard to the impregnation of the human ovum still haunt our text-books and college halls. They maintained that, after an ovum reached the Fallopian tube it remained in its lumen until such time as a spermatozoid came along and impregnated it. Speaking in a broad, general way, the more one contemplates the subject of menstruation the more does one come to realize that, in order to fully understand the mysterious principles that are called into action, it obliges us to comprehend the subject all along the scale, from the lowest order of animals up through intermediate stages, until we come to the highest specimen of animal life, namely, that of man. The subject, therefore, presents itself in a much broader light than was formerly, or is now generally, supposed.

In such investigation, we find that, according to each phase of evolution, essential principles are required, and actually exist, for the maintenance of each distinct species. We find that they are governed, not by any one law, but by the requirements for the propagation and existence of each distinct species, and that no two are

governed exactly alike. These theories may, at the first blush, appear revolutionary and heretical, but recent investigations seem to prove their accuracy. The belief that impregnation takes place in the Fallopian tubes we have found to be an erroneous deduction, by investigation upon the lower animals. As a matter of fact, the Fallopian tubes do not exist as such except in those animals that assume an upright position. Granting this hypothesis, and I cannot imagine a belief that can gainsay the truthfulness of it, the ætiology of normal fecundation becomes much more intelligible. When we consider the erroneous opinions that have been maintained on these subjects, it is little wonder, is it not, that the ætiology and pathology of ectopic pregnancy have remained for so long a time enshrouded in confusion and doubt? As the mysteries surrounding this matter became unraveled, a flood of light was thrown upon the cause of the ectopic variety. It is astonishing, however, how the subject is still misunderstood, and the consequence is that a vast amount of confusion and uncertainty exists upon many points of this peculiar condition. Traces of this can frequently be seen in many of our text-books and in the medical literature. The amazing strides of abdominal surgery during the last fifteen years have been the means, in their gigantic sweep, of elucidating, more than anything else, this peculiar form of pregnancy.

It would be carrying the subject beyond the scope of my present purpose to array before you in full the various theories that have been maintained upon the subject of animal fecundation. It is, however, interesting, as a piece of medical history, to contemplate the different and discordant opinions that have been maintained upon this subject; for example, the ancients believed that a vapor passed from the seminal fluid to the ovum, thereby fertilizing it. Again, the theory that the seminal fluid was absorbed, and through the circulation reached the ovum, was held for a time, and so on in this manner has the subject become much confused. If this latter theory were the correct one, there can be little doubt there would be many more cases of tubal gestation than we at this time have. Sufficient knowledge of the functions of the ciliated epithelium of the Fallopian tubes establishes the fact that impregnation normally takes place in the uterine cavity. The cilia, by their peculiar formation and action, propel the ovum down the tubes to the uterus, at the same time preventing the spermatozoid from ascending. When the ciliated epithelium becomes destroyed, the ovum will remain in the tube, and, there being nothing to prevent the spermatozoid from ascending, it meets the ovum in the tube. There fertilization takes place and the ovum becomes adherent to the walls of the tube and goes on developing. This delicate membrane then becomes of enormous importance in the regulation of the normal functions of reproduction, and its destruction places the life of any married woman in constant jeopardy. This

theory not only explains sufficiently well the causes of extra-uterine pregnancy, but places our opinions of normal gestation where they ought to belong. We may conclude, therefore, that all ectopic pregnancies are originally tubal, but that it will depend upon several conditions what the future history of any such pregnancy will be. Should impregnation take place in that part of the tube that passes through the uterus, we get what is called the interstitial variety. This form is one of the most difficult to diagnosticate from normal pregnancy. Such pregnancies invariably rupture into the peritoneal cavity, and are universally fatal unless a surgeon chances to be near at hand and possesses the moral courage to operate without delay. A feature quite noticeable in the histories given in such cases is, that the woman has shown a previous inaptitude for conception, or, if she has given birth to a child, there has intervened a long period of sterility. An ectopic pregnancy in any part of the tube necessitates rupture. This may take place any time before the fourth month, generally between the twelfth and sixteenth week. According to the direction in which the rupture takes place, you will have a disastrous catastrophe, or one of comparative safety—*i. e.*, a rupture upward into the peritoneal cavity, or downward. The former variety is known as intraperitoneal, and the latter as extraperitoneal. There are many classifications other than this, but those I mention have been given by various authorities. Many of them are more or less misleading or confusing, and have, no doubt, been formulated upon erroneous opinions of the pathology. If, however, the principal and fundamental theory, that every case is originally a tubal one, is remembered, the subdivisions become apparent and intelligible. When the fœtus develops at or near the fimbriated extremity, it almost invariably ruptures inward; when, in these instances, it survives, it may go on developing in the abdominal cavity.

It is unfortunate that the term abdominal pregnancy has been applied in these cases, because the placenta still remains attached to the tube. Under this head come those cases in which secondary rupture has taken place. A form of the extra-uterine variety frequently discussed is the ovarian. Its existence has been contested, and strangely dogmatic views have been maintained upon the subject. I know the difficulties that are frequently experienced by expert pathologists in distinguishing the relationship of certain pathological specimens. That the ovarian tissue is often found adherent to the sac in ectopic pregnancy is no reason that we should conclude that the fœtus originally developed from the ovary itself. Growths like these, especially when considerable exudations are thrown out, stretch and contract the tubes and ovaries beyond recognition. Such is especially true when development goes on after the downward rupture and before the secondary rupture. Some of the reported cases of abdominal pregnancy are

probably not authenticated, and the trend of opinion is rapidly coming to the conclusion that it does not take place, but that such cases are due to the stretching of the ovarian tissues against the rapidly distending walls of the extraperitoneal variety.

Much discussion has taken place as to the early diagnosis of this anomaly. A feature quite noticeable, and one that is suggestive in these discussions, is that the men who have had experience in the matter sufficient to enable them to speak from a practical standpoint, are almost unanimous in their declaration that accuracy in the early stages of such diagnosis is far from being satisfactory; whereas the parties who confine themselves to literary work and the play of their imagination, and those who have had little experience, are quite agreed in their assertions that the diagnosis should be accurately made. They even go so far as to say that this can be accomplished with greater ease and certainty than in normal pregnancy. While but a small proportion of those whom we examine will have a line of symptoms sufficiently clear to enable the physician to come to a clear and accurate diagnosis, yet there is a large proportion who do not complain of anything so unusual as to seek advice until all of a sudden the rapidly distending tube, whose walls are getting thinner every day, gives way, and the patient is immediately whirled into a precipice of danger that contrasts in its awfulness with the peace and serenity of her previous symptoms. So we are met at the threshold with the almost insurmountable difficulty that not more than ten or fifteen per cent. complain of such unusual state of health as to demand our attention. Many of those who do consult the physician are either wanting entirely in symptoms, or give such an erratic and irregular history of the case as to render it absolutely untrustworthy. The symptoms that are sometimes present in normal pregnancy are frequently altogether different from those found in the ectopic variety. Herein have erred the theoretical party, and those who claim to have cured such cases by the electrolytic treatment, or by applying with mathematical exactness the cut and dried symptoms of normal gestation. They err again in comparing the rather confusing symptoms of rupture with those usually accompanied and followed by that event. It is accepted that the rapidly growing fœtus so dilates the tube as to cause rupture at some period. In ordinary pregnancy few symptoms or signs are reliable up to the second or third month.

But few women would suspect pregnancy were it not for the cessation of menstruation and occasional morning sickness. In the early period of tubal pregnancy, these signs are often found wanting. There can, however, be very little doubt that there are cases where an almost positive diagnosis can be made, by one who has given any study and consideration to the subject, but the percentage must necessarily remain small, and must render them of little consequence when compared

with the large number that will remain unrecognized for the reasons I have already given.

When rupture takes place into the peritoneal cavity, there are alarming and characteristic symptoms of pain and collapse. There will be colic, distention, vomiting, thin, rapid pulse, coldness of hands and feet, and the patient may faint away. By the aid of rest and stimulants, she may recover, only to be taken with a similar attack unless a surgeon, recognizing the condition, immediately cuts down to the base of the broad ligament and secures the bleeding vessels.

Until a few years ago, when surgical aid came to their assistance, such cases were left and abandoned to their inevitable fate. The woman having extra-uterine pregnancy is entirely at the mercy of accidents, and it can be truthfully said she is only safe when upon the operating table. She can have no warning signal of the many pitfalls that lie in her path. Throughout all its existence, dangers surround and encompass her. In the early period, there are dangers of hæmorrhage; when this is subperitoneal, the patient generally survives to a later period. Peritonitis and suppuration of the sac may continue for an indefinite period. Injury to the bladder and other viscera is frequent. The constitution may become undermined and the patient gradually sink unless surgical aid is secured. The symptoms of ectopic pregnancy are sometimes very irregular. Occasionally the patient presents all the signs of normal pregnancy, but generally many of the usual symptoms are entirely lacking. Frequently menstruation ceases and subsequently returns irregularly. One symptom that is generally accepted as pathognomonic is the expulsion of the decidual membrane. This, however, does not always take place, or, if it does, it is not recognized; sometimes an enlargement is discernible, but usually not before the period of rupture. More frequently the patient complains of vague pains and uncertain symptoms for which she does not even consult her physician.

When the rupture takes the downward position between the folds of the broad ligament, the symptoms will not be so alarming, the pain not so severe, and the chances of the child surviving become more favorable. Inflammatory exudations are thrown out, pressing on the bladder, causing incontinence of urine, intestinal colic, diarrhœa, or constipation. A condition that is generally present in this variety is an annular constriction of the rectum. Frequently it will perish, and become evacuated in the shape of pus. The pus may break into the rectum, the vagina, or bladder. Many cases are mistaken for a pyosalpinx which are but broken-down tubular pregnancies. These terminations are unfortunate, as they tend to remain suppurating centres, rendering their victims chronic invalids. Sometimes the sac becomes absorbed. This, however, is not to be looked for, because it is extremely rare.

The sac sometimes becomes calcified, and remains as a foreign body imbedded; it is then called a lithopædion.

Several queer incidents of such have been recorded. When the fœtus remains viable, the diagnosis becomes comparatively easy, as you will then have foetal heart sounds, sympathetic and other reflex symptoms. There were peculiar conditions that upon two occasions taxed my diagnostic ingenuity to the utmost to enable me to determine between normal gestation and one of the ectopic variety. A peculiar condition sometimes found in normal pregnancy, and one which is very puzzling, is extreme thinness of the abdominal and uterine walls. I have seen very little mention of this anomaly. Why is it that very rarely during normal pregnancy both the uterine and abdominal walls become so thin that you can detect under your fingers every part of the fœtus, even to the toes and fingers? With my first patient, there was a condition of elevation of temperature for three months. I had at one time concluded that I had an extra-uterine fœtus to remove, but during the last two months the walls of the uterus and abdomen became thicker, and the woman had in every way a satisfactory delivery.

(To be continued.)

ICHTHYOL IN TREATMENT OF DEEP-SEATED INFLAMMATIONS.

By WALTER T. SLEVIN, M. D.,

BROOKLYN.

AFTER having used ichthyol in a number of different formulæ where the resultant action has not been as desired, I have at last obtained a formula which, if used properly, will relieve deep-seated, as well as superficial, inflammations.

The formula is as follows:

℞ Ichthyol.	45 grains;
Lead iodide.	45 "
Ammonium chloride.	10 "
Petrolatum, enough to make.	1 ounce.

The substitution of glycerin, rose ointment, or cacao butter does not alter its efficiency.

It should be applied by rubbing upon the inflamed parts. The results of the application in three different cases are here described:

CASE I.—James F., aged twenty-one years, had a marked swelling on both sides of face, involving the nose and extending to the eyes, with high fever, great prostration, and partial delirium.

Diagnosis: Erysipelas.

Treatment: Had the preparation rubbed into site of inflammation every hour; subsidence of the condition in twenty-four hours.

CASE II.—Mary McN., aged thirty years, had a large swelling on left side of the face, involving the glands of face and neck; could not open the mouth; high fever; dyspnœa; dysphagia, and appearance of impending death. The swelling was very hard and tense; therefore to incise it would be futile.

Diagnosis: Circumtonsillar abscess (quinsy sore throat).

Treatment: Application of the preparation every hour, with cure in twelve hours.

CASE III.—John C., aged six months; râles over both sides of the chest; bronchial breathing; bronchophony and slight dyspnoea.

Diagnosis: Bronchopneumonia.

Treatment: The preparation was rubbed into chest, and all symptoms disappeared on the following day.

From the cases described it can be readily seen that in acute inflammatory conditions the results have been most excellent.

It seems to me that this formula should be most effective when used in chronic conditions, inflammations, glandular enlargements, and ulcerations, whether of specific nature or otherwise, as it is a great aid to absorption.

I trust that this formula will be made use of by the profession and its effects reported.

386 UNION STREET.

RESORCIN AS A PRESERVATIVE FOR SUPRARENAL EXTRACT SOLUTION.*

BY SEYMOUR OPPENHEIMER, M. D.,

NEW YORK,

INSTRUCTOR IN LARYNGOLOGY, UNIVERSITY MEDICAL COLLEGE;
FELLOW OF THE AMERICAN LARYNGOLOGICAL SOCIETY, ETC.

THE most serious difficulty in obtaining a satisfactory aqueous extract of the suprarenal gland has been the necessity of making a solution that would not decompose and cause infection when applied. Since the drug has come into general use, numerous formulæ have been recommended in which a preservative is added to prevent putrefactive changes. Of the many drugs used for this purpose, boric acid, camphor, glycerin, bichloride of mercury, the various silver salts, and alcohol have received the most attention. Boiling the aqueous solution has to some extent also been advised for this purpose, but this method falls far short of its aim, as it only insures that the solution remain sterile for a very short time.

Boric acid will undoubtedly preserve the active portion of the gland for several weeks, and the same can be said of glycerin and weak alcohol solution, but the addition of these substances to the suprarenal extract materially weakens its physiological effect. Camphor or any preservative with a distinctive odor should never be used for this purpose, as it is practically impossible to detect changes in the solution until they become apparent to the eye, on account of the powerful odor of the preservative masking the odor of decomposition.

I have found that the metallic preservatives, as silver and mercury, whether in organic combinations or not,

produce a precipitate in conjunction with the suprarenal, making the solution practically worthless, as it diminishes the vasomotor constrictor action, and within a short time the solution becomes to a great extent inert.

Two important objects are essential to the production of a solution of the suprarenal capsule that will be physiologically active and produce its maximum vasoconstrictor action when locally applied to the mucous membrane. First, the prevention of the putrefactive changes that result on account of the large proportion of animal matter present in the desiccated powder, and, secondly, the preservative used must be nontoxic and must not impair in any way the full efficiency of the gland.

These requirements, in my experience, are all fulfilled by the addition of resorcin, which, while retaining its preservative qualities, is not, in the strength here used, an irritant to the mucous membrane, and is not, like the majority of drugs, incompatible, thus impairing the value of the suprarenal.

A series of experiments to determine the usefulness of this drug for the purpose mentioned was undertaken on guinea-pigs. A one-per-cent. solution of resorcin in sterile water was prepared, to which the desiccated gland was added in the proportion of sixty grains to the ounce, and one cubic centimetre of the filtrate was injected into the peritoneal cavity of guinea-pigs at various times and covering a period of several months. In every instance it was found to be non-infectious, the animals showing no evidence, local or otherwise, of any septic effects from the inoculations.

A series of clinical tests was then undertaken by applying the solution, when filtered, to the nasal mucosa, and it was found in every instance that there ensued prompt contraction of the vascular walls, differing in no way from that produced by the fresh aqueous solution of the gland. This maximum energy was not diminished by age, as the active physiological results were obtained and were as well marked in the fresh solution as in that used at the expiration of six months after it had been first prepared. At the same time the solutions showed no evidence of bacterial change, remaining perfectly sterile for an indefinite period. By the use of a one-per-cent. aqueous solution of resorcin, therefore, an almost permanent solution can be obtained, thus eliminating the annoyance of having to prepare a fresh solution whenever the drug is applied.

For practical purposes, it is my habit to add sixty grains of a good desiccated suprarenal extract to one ounce of the resorcin solution. The quantity necessary for daily use is filtered, thus obtaining a clear aqueous solution. It is not my desire here to mention the numerous uses to which the suprarenal gland may be applied, but, as a hæmostatic and vasomotor constrictor, this solution can be recommended to you as being of great service.

706 MADISON AVENUE.

THE RADICAL TREATMENT OF MALIGNANT DISEASE OF THE LARYNX.

By ERNEST WAGGETT, M. B., B. C., Cantab.,

LONDON, ENGLAND,

SURGEON TO THE LONDON THROAT HOSPITAL, AND TO THE OUT-
PATIENT THROAT DEPARTMENT, GREAT NORTHERN CENTRAL
HOSPITAL.

IN Professor John Noland Mackenzie's article upon the Surgery of Laryngeal Cancer (*New York Medical Journal*, September 8, 1900), the last word appears to have been said upon the subject of the radical operation. "Early total extirpation of the entire organ, with its tributary lymphatics and glands, whether the latter are apparently diseased or not, is the only possible safeguard against local recurrence or metastasis. By no other method can we give the patient a reasonable assurance of a permanent lease on life."

It is much to be regretted that the writer adds no statistical data of the assurance which he expresses in the first part of this sentence, for this cannot but remain unconvincing without some such support. A removal of all the glands in any way related to the lymphatic circulation of the larynx, coupled with the extirpation of the diseased organ, should indeed prove a safeguard against local recurrence; but without evidence of the possibility of so complete and radical a measure, we must remain skeptical of the practical utility of the advice which the writer gives us. Where are we to draw the boundaries of the susceptible lymphatic area? In the case of malignant disease of the breast, actual experience would seem to have limited the dangerous area of the large majority of cases, but in the case of the larynx, can such a line ever be drawn by the experience of operators? Certainly not until we have a more competent mastery of the surgery of the chest.

I have in my mind a case of carcinoma of the larynx in which, at the autopsy, no evidence of lymphatic infection was met with until an enlarged gland, proved by microscopical examination to be carcinomatous, was detected in the neighborhood of the right bronchus.

Instances of the involvement of lymphatic glands within the thorax must occur to many observers, and will illustrate the force of my doubt.

It may be replied that, in the majority of cases, the area of danger lies wholly outside the thorax and within the "operable" regions, but before we can accept that statement we must receive convincing proof of its truth.

The distinguished position of the author of the remarks under consideration and the *ex cathedra* character of their delivery at the annual congress of the American Laryngological Association are matters which emphasize the need of carefully weighing the purport of the words. These words would seem at once to offer us a means of almost certain cure—"a safeguard against local recurrence"—and thereby cut at the root of a hope and confidence which has been steadily growing in this country for the past thirteen years.

The basis of our work in Great Britain has been early diagnosis, and our guiding motive the maximum of cures with the minimum of mutilation. In theory, what could be more rational? But in practice, what has been the outcome?

Unlike Professor Mackenzie, we have an answer to give. In the words of the writer of the *Mikado*, we have "made the punishment fit the crime," and ten years' experience has justified this laudable motive.

For Professor Mackenzie there are "exceptional cases" (page 399) which may be dealt with otherwise but "the general rule of practice shall be total extirpation with the neighboring area of possible (!) lymphatic infection." For British laryngologists the whole aim and endeavor has been to bring these exceptional and limited cases into the forefront and, by constant preaching to students, to drag the early cases into the sphere of operative surgery. To the younger laryngologists in this country it does indeed seem wide of the mark for the opener of a debate in one of the most prominent of laryngological associations to entitle his work *A Plea for Early Naked-eye Diagnosis*, and finally to descend to what is here considered the low-water mark in the matter, namely, "the extirpation of the entire organ."

And surely the author of the article under consideration reveals a curious misapprehension of the surgery of malignant disease of the larynx in the following sentence: "Thyreotomy with curettement or removal of all apparent (visible) disease is not up-to-date surgery is in direct defiance of the rules that should govern us in the treatment of cancer, and is a reversion to, and a resurrection of, a method of procedure that was discredited and abandoned over half a century ago." The truth contained, in fact, in this statement is indeed a travesty of the truth, and as such is the more misleading. One may say that even less than a quarter of a century ago thyreotomy received its death-blow at the hands of Paul Bruns, who, in 1878, was able to report nineteen cases, with two deaths from operation, sixteen local recurrences, and one death from adrenal cancer. Thyreotomy, indeed, died, and was scarcely practised for a decade, but is not the author aware that the name of what has been happily nicknamed "the incomplete operation," has been given again to a wholly new operation, based on sound theoretic foundations, carried out with minute regard to new technical possibilities, and followed by brilliant surgical results? The new thyreotomy may be said to have been born in 1888 under the auspices of surgeons of the widest experience. Even before this, in 1886, Semon (*Heath's Dictionary of Surgery*, and *Centralblatt für Laryngologie*, 1887, Vol. v) drew attention to the earliest diagnostic features of malignant disease of the larynx. Somewhat later, B. Fraenkel stated his agreement with most of Semon's diagnostic points. But from 1888 thyreotomy took a new place in British surgery, when Butlin first broke away from the doctrine of Bruns, and, in the thirteen

years which have followed, the brilliant results of British laryngological surgery have engendered a new hope and confidence, as I have said, in this deplorable affair of malignant disease of the larynx.

In the interests, then, of American surgeons, and still more of American patients, let it be said that there is a new thyrotomy and a new statistics—a statistics which is overwhelmingly more favorable than that of any other radical operation for malignant disease of the larynx.

In the first place, it is worth noticing that Sendziak's statistical tables, including all available cases between 1851 and 1894, show as in Table I:

TABLE I.

	Number of cases.	Deaths from operation.	Recurrence.	Good results—free from recurrence at end of 1 year.	Cures—free from recurrence at end of 3 years.
total extirpation.....	188	44.7%	32.4%	12.8%	5.85%
thyrotomy.....	85	9.8%	53.3%	13%	8.7%

Even these data, commencing, be it noted, from 1851, give a more favorable set of results for the smaller than for the larger operation, while the operative mortality is greatly in favor of thyrotomy.

But now mark the difference in the figures when, on a rational basis, the old thyrotomy is separated from the new thyrotomy.

And, in parenthesis, one might ask the general surgeon, What is the mortality for the operation of ovariectomy? For the first hundred ovariectomies the mortality was 34 per cent. At a later date the figure came to 11 per cent., and I understand that some few years back it was from 2 to 3 per cent., and that consecutive centuries of the operation have yielded no deaths. In computing the risks for his patient, what is the mortality figure in the surgeon's mind? Does he include the first hundred cases among his figures in forming an estimate of the dangers to life up to date?

So with thyrotomy, let us divide Sendziak's figures according to date. From 1851 to 1888 the definite three-year cures came to 8.7 per cent. for thyrotomy. Divided into the categories before and after the birth of the new thyrotomy, the figures stand as in Table II:

TABLE II.

Thyrotomy—1851 to 1888—definite 3-year cures.....	6.4%
“ —1888 to 1894— “ “ “	29.9%

The new thyrotomy gives, then, a percentage of 29.9 of three-year cures, against 5.85 per cent. after total extirpation.

Now, this in no wise hits at Professor Mackenzie's contention for a new total extirpation which shall include the removal of the whole area of possible gland

infection, and the question still remains—shall we make trial of his new method of which we have no statistics, or shall we take early thyrotomy as our desideratum?

First, his new operation. Is it truly a desideratum, or is it a forlorn hope, to be undertaken in the exceptional cases where operation is just feasible and thyrotomy out of the question? The life of a man deprived of his larynx is not a happy one. At least four successful patients have exemplified their views on the subject by committing suicide. Those endowed with more fortitude lead but a maimed existence, either whispering by means of the expulsion of the air contained in the mouth and pharynx, or dependent on the caprice of an artificial larynx which, when perfectly clean, gives them a monotonous voice; some are free, it is true, from the escape of saliva from a pharyngeal fistula, but none are able to fix the chest walls in preparation for a muscular effort. All wear a tracheal tube and all have passed through an ordeal which, in spite of Professor Mackenzie's contention that the dangers of an immediate fatal result are avoidable by modern surgeons, has hitherto availed to bring 44.7 per cent. (Sendziak's table) to their death within a few days. Are they free from all danger of recurrence? This will depend upon the completeness of the mediastinal interference, of which we have yet to learn the technique. Short of something unheard of in the way of radicalism, they are not really free even after the passage of the three-year limit, for the reader of Sendziak's paper will recall the cases reported by Navarro and by Hahn, in which recurrence occurred after six years and eight and a half, respectively. So much for the total extirpation case—the triumph of radical surgery—the pathetic picture of a maimed, pitiable man, scarcely able to earn a living, and not even secure against recurrence!

And now let us consider if we are justified in trifling with a case of laryngeal malignant disease by the method of thyrotomy as practised in England in suitable cases. It would be impertinent in me to draw a picture of the suitable case, as it has been already clearly described by distinguished authors and accepted by eminent American surgeons at the meeting of the British Medical Association in 1895.

First, and least important it is true, it is to be observed that the comfort and ability of the successful thyrotomy case is almost complete. There is, of course, no fistula and no tracheal tube. The voice must always be the last consideration in the matter, but Semon, well recognizing this fact, records the vocal results in ten of his successful cases thus:

Voice good.	6
Voice weak, but better than before operation.	2
Whisper.	2

Secondly, what is the death rate for the new thyrotomy? Now, the technique of the operation has been minutely stated by two authors, Semon and Butlin, and

the improvements made from year to year punctually noted. It is, therefore, only fair to record the results of those operators who have had large opportunities of conforming to these details. Butlin's results are, I believe, at this moment being brought up to date, and are not available for this article, but Semon's have appeared as lately as November, 1899 (*Monatsschrift für Ohrenheilkunde*), a fact which the silence of Professor Mackenzie leads me to think he has overlooked.

Semon's death rate from operation for the period 1888 to 1897, including the early cases which served to invite rather than exemplify a final and improved form of operation, amounts to 6.66 per cent. In a word, out of fifteen patients, one died from the operation, and he was a chronic bronchitic, seventy-two years of age.

And now, finally, can we give the patient a reasonable assurance of a permanent lease on life after thyreotomy? I presume the reasonableness of the surgeon's assurance in any case of malignant disease occurring in any part of the body will in a measure be left to the final judgment of the patient or his friends. And what data can we offer on which he or they can base their opinion before acceding to the advice of the surgeon, when on scientific grounds he advises thyreotomy for malignant disease of the larynx? An answer to this inquiry can be found in Semon's latest paper (*Monatsschrift für Ohrenheilkunde*, November, 1899). We are at this moment not concerned in a criticism of Sendziak's later work, and need not follow Semon where he points out: 1. That thyreotomy, as we regard it in this country, includes, where necessary, the removal of small particles of cartilage. This proceeding in no wise alters the character of the operation or the manner of after-treatment, and cannot be held to constitute a partial extirpation. 2. That the three-year limit of cure is a purely arbitrary one, seeing that the great majority of recurrences take place within a few months of operation, and in reality denote incomplete removal. Semon, indeed, regards freedom from recurrence after one year as sufficient to constitute a cure, and his personal experience and an examination of Sendziak's list would seem to fully justify his view. But let that pass, and let us take the three-year limit. Semon's figures for thyreotomy performed upon twelve cases of malignant disease of the larynx, all of them proved to be such by microscopic examination (Shattock), stand as in Table III.

TABLE III.

Cases.	Death from operation.	Recurrence.	Sound more than one year.	Sound more than 3 years.
12	1	1 (doubtful)	10	6

The six cases which remain free from recurrence more than three years after operation represent the results of eight thyreotomies, which amounts to no less than 75 per cent. of definite cures.

Into a second category we may place the four cases well more than one year after operation. These repre-

sent the result of four operations, or 100 per cent. Semon himself sees no good reason for this division in two categories, and computes his percentage of cure (*i. e.*, more than one year free from recurrence) as 83 per cent., or ten out of twelve operations.

We are not, however, likely to enter into any dispute as to the exact percentage, for the figures are so infinitely superior to those of total extirpation that they scarcely come into comparison. I bring these percentages forward simply to show that thyreotomy, as practised by Semon, Butlin, and a large number of British surgeons is an operation which yields brilliant results. A man's thought will convince the reader that, in face of such results, it is absurd to sweep aside thyreotomy with the remark that it is an operation which half a century ago was discredited and abandoned. Professor Mackenzie's new operation may, it is true, give us a better percentage of three-year cures than 75 per cent., but meanwhile we await the results of his experience in the matter. For the present his operation must remain in the doubtful stage of experiment, and by no means be thrust upon the public from a presidential chair as the only rational safeguard against recurrence.

In the interests, not less of American patients than of American surgeons, it has seemed to me necessary to bring this matter forward, and I must do so with a light heart, for almost every word that I have written has been already said again and again by surgeons of experience and acknowledged prominence. Thyreotomy is not for the first time ignored by writers on malignant disease of the larynx, and no doubt this is due to the fact that the majority of cases seen in hospitals have already passed the stage in which the most extensive operation that can be imagined is out of the question. In the routine of daily work at the hospital, thyreotomy must indeed but seldom come into question; but, on the other hand, our hopes in attacking laryngeal cancer do not rely upon an increasingly extensive method of operating.

Figures show very clearly that success in the matter depends rather upon the limitation of the disease than upon the degree of the surgical mutilation.

Early diagnosis, all will admit, must be the watchword of the thoughtful and progressive surgeon, but as we enter a new century armed with growing abilities to recognize the first stages of laryngeal cancer, we must not abandon a victory already developing and convert an orderly advance into a kind of forlorn hope. Thyreotomy, as now practised, is doing admirable work; it cannot be repressed in favor of an operation which has yet to win our confidence; and which, at best, can offer the patient an insecure lease of life, purchased at a terribly heavy premium.

The German Dermatological Congress will be held at Breslau on May 28th, 29th and 30th.

THE SURGERY OF THE TURBINAL BODIES,
WITH A NEW METHOD OF OPERATING.*

BY J. E. BOYLAN, M. D.,

CINCINNATI, O.

THE method of dealing with hypertrophy and degenerative changes in the turbinated bodies—common to these conditions are, and fraught with dire consequences—is undoubtedly one of the most important, interesting and persistent problems which it is the task of the rhinologist specially to solve. I offer no apology, therefore, for introducing to you this familiar, though not trite, subject. Glancing back over very few years, we realize at once that the series of momentous observations made in this field by Virchow, Hack, Kölliker, Kohlrausch, Zuckerkandl, and Biglow not only have proved of absorbing interest to the physiologist and pathologist, but have been happily followed by triumphant practical results, that thousands of patients to-day find relief from a condition which, before the anatomy and function of the turbinated tissue were understood, remained a dreaded bugbear to the physician. But the great progress made in this short period, as well as the good results attained at times by very crude methods, only tends to strengthen the assumption that, far from being an exhausted field, this is one in which a comparison of methods is likely to lead to much better results in the future.

In days gone by, I have resorted to different procedures one by one, as they were developed by the rapid march of rhinology: Linear incision with the galvanocautery knife in soft hypertrophy; the use of chromic acid and the chloracetic acids; the more extensive surface reduction with the cautery blade, in excessive indurated hypertrophy, and in many instances the gradual reduction of the extremities of the bodies, from which the best results were obtained.

As time progressed, however, and the accumulation of cases afforded an opportunity of convincing myself of the preponderance of hypertrophy in certain regions, notably at the extremities, rather than in the central part of the bodies, I resorted with increasing frequency to the removal of larger segments of the excessive tissue by the smooth operation, and the results attained proved so satisfactory that I now give this procedure the first place in the treatment of this condition and believe that in the advanced hypertrophy so frequently associated with interference with the respiratory function the judicious amputation of portions of the turbinated bodies will be the operation of the future in rhinology.

In support of this postulate, let me recall that the hypertrophy in question, whether always originating in the erectile tissue or not, has its chief development in and about its walls, as the result of chronic engorgement, this being not a matter of theoretical conjecture, but a

demonstrated fact, as the result of microscopic research, notably by our fellow, Dr. J. N. Mackenzie;* further, that the location, or at least the great preponderance of this tissue, is near the posterior and anterior extremities and in less degree—in the lower part and along the free margin of the middle and lower turbinated bodies. Thus, Zuckerkandl,† who has made an exhaustive study of this tissue, states: “The autopsy has determined that in the engorgement of the turbinated bodies the posterior extremities are most increased in size, the middle part the least; this being easily explained when we consider that there is less need of erectile tissue upon the convex, protruding middle part of the body, than at the pointed (*zugespitzten*) extremities.”

The conclusions following are drawn from 111 turbinotomies in private practice, and from clinical cases in which a record has been kept; 42 of which were examined at least one year after the date of the operation. The conclusions are: 1. That, while in exceptional cases involvement of the whole erectile-tissue area of the pendulous portion of the body may coexist, hypertrophy is usually greatest where this tissue is most abundant—namely, at the anterior and posterior extremities.

2. That the relief of obstruction and the reduction of hypertrophy in these cases is accomplished more certainly and scientifically by ablation than by cauterization.

3. That, while venous dilatation is greatest at the posterior extremities, obstruction is rarely due to hyperplasia at this point *alone*.

The reason for the prevalence of the erectile tissue in the region of the choanæ must be obvious, if we accept the proposition that it is part of Nature's plan to have the air pass in thin sheets between closely approximated walls for the warming and moistening process so essential to perfect respiration; the posterior opening, being not only quite straight, but widened to a lumen much larger than the narrow passage in the vestibule, naturally requires a larger supplement of erectile tissue to produce in this region the condition referred to, and it is owing to this free posterior opening that a greater degree of engorgement or hypertrophy may here exist without obstruction.

Without dwelling further on this phase of the subject, however, I pass to the consideration of the method of operating which it is the object of this paper to describe.

To deal as briefly as possible with statistics, in the cases above referred to, the lower part of the inferior turbinated body was removed throughout its entire length in three instances with the saw, and in twenty further cases sections embracing the anterior extremity, with the same instrument. In twenty-four cases turbinotomy of the lower or middle body was performed with the scissors, or with the saw and scissors together,

*Read before the American Laryngological Association at its Twenty-second Annual Congress.

**Medical News*, 1884.

†*Wiener medicinische Wochenschrift*, 1884, p. 1125.

and in sixty-four cases sections of varying size were removed with the cold snare.

The clean, smooth edge of the cut made by the transverse passage of the wire through the body, the small amount of hæmorrhage, and the possibility of following the loop with the eye quite to the point to be reached commended this latter method to me above the others, and the use of the saw and the scissors was in time restricted to cases in which excessive induration suggested an exceptionally thickened bone. If in any of these sixty-four cases the turbinated bone was ever seriously crushed with the loop, I have never been able to detect it, and have certainly never once known either an osteitis or any deformity to result. If the wire used is stiff and thin, and the snare powerful, the tissue is cut through smoothly and usually with ease.

A serious objection to this method, however, was the slipping forward of the loop over the medial surface and lower margin of the body, at times even after it had been inserted into a short incision dividing the anterior extremity of the body from the side wall, by which slipping either a complete failure to engage the tissue resulted or the amount removed was much less than had been intended. To prevent this accident, it occurred to me that the end of the loop might be fixed by burying the point of a fine tenaculum, the hook of which formed a right angle, into the lower margin of the turbinated body at the point of operation, carrying the loop over its handle into the meatus and adjusting it so that it passed behind and was held in place by the back of the hook. This device, first tried upon the middle turbinated body, proved entirely successful, and has since been used with gratifying results in numerous cases. By means of it it is possible to entirely control the removal of the amount of tissue required, and, combined, if necessary, with the lateral incision above referred to, amputation can be done with accuracy as far back as the middle of the body. Finding that the point of the hook was at times caught in the loops, I afterward had this bent to an angle somewhat more acute than a right angle, and in operating it was tilted still farther forward by depressing the proximal end of the tenaculum. During the manipulation the snare should be pressed firmly backward and upward, so that the loop is drawn from above rather than from in front. The back of the hook is corrugated for the better retention of the loop.

The method just described was not applicable to cases in which the removal of the posterior extremities of the lower bodies was performed with the snare, this being usually accomplished by conjoined manipulation through the mouth—in two cases with great difficulty—twice under anæsthesia. The proportion of cases, however, in which obstruction rendered this operation imperative was surprisingly small—they numbered twelve.

In eighteen cases in which marked enlargement of the posterior extremities coexisted with causes of obstruction farther forward, such as polypi, hypertrophy

at the anterior extremities, or of the lower margin of the body, and irregularities of the sæptum, the removal of the latter sufficed to restore the lumen of the passage, after which the posterior hypertrophy was no longer a source of serious annoyance, and in several instances receded rapidly under local treatment. A diminution of hypertrophy at the two posterior extremities, I may add, I have repeatedly observed after the removal of adenoid vegetations and enlarged tonsils.

The principle involved in turbinotomy is the radical removal of that part of the tissue which is the final cause of obstruction, and in which hypertrophy is furthest advanced, leaving the less affected part, which is to perform the function of the body, uninjured by operative procedures. The indication is to remove as little tissue as possible consistent with the freeing of the passages from obstruction to respiration.

A comparison of results obtained by this method with those from the use of the cautery will, I believe, operate more and more to restrict extensive burning out of the nose in the days to come. If cauterization is sufficient to materially reduce the hypertrophy, the process must of necessity result in the wholesale destruction of the glands so essential to the function of these bodies, and the conversion of an already diseased tissue into a cicatricial one.

In forty-two of the cases referred to it was my fortune to inspect the patient at least one year after operating; in no instance was there a complaint of discomfort attributable to the operation, while I regret to say that in a number of cases in which the cautery was used inspection now shows in some instances, instead of the normally curved body at the site of operation, a flat, dry, resisting surface, giving rise at times to an annoying sense of dryness, while in others the process has not been arrested, but has continued to develop, either beneath the tissue cauterized or in immediately adjacent parts.

The number of cases reported in which troublesome adhesions, septic inflammation, and—the one case, at least, Dr. Quinlan's—in which meningitis resulted from cauterization of the middle turbinated body, should preclude the use of the galvanocautery in this region at least. The method above described has the great advantage over the use of scissors that the view is not obstructed by the instrument. This is particularly apparent in resection of the middle turbinated body, so frequently necessitated by disease of the ethmoidal sinuses, in which procedure the application of either scissors or saw may be extremely difficult.

The St. Louis Medical Society of Missouri.—At the last regular meeting, on Saturday evening, the 2d inst., Dr. William A. McCandless read a paper entitled *The Removal of Foreign Body from the Bronchus*, with a Report of Cases.

Therapeutical Notes.

Pastilles for Painful Affections of the Throat.—

Neumeier (*Pharmaceutische Centralhalle*, January 17th) uses the following formula for pastilles in anginal affections of the throat:

- R Borax. 1½ grains;
- Cocaine. ⅓ of a grain;
- Antipyrine. 3¼ grains.

M.

From four to eight pastilles may be used daily for an adult, and smaller doses for children.

A Movement Treatment for Vertigo.—M. Urbantschisch (*Indépendance médicale*, February 25th), at a recent meeting of the Imperio-Royal Society of Medicine of Vienna, said that, having noticed that the sensations of vertigo determined, even in the normal state, by rotary movements of the head, were proportionately more tardy of production as the subject was accustomed to execute such movements, he had prescribed frequent rotary movements of the head to many patients subject to vertigo. The patient, lying down, turned the head alternately from side to side, stopping as soon as vertigo appeared. When certain movements of the head or the eyes alone provoked the sensation of vertigo, he caused these movements to be practised to the exclusion of others. After a certain time the use of these manoeuvres induced the complete disappearance of the trouble. He had thus succeeded in curing the vertigo of a patient, which, following on the radical cure of a caries of the petrous portion of the temporal bone, was recognized as having its cause in a lesion of the horizontal semicircular canal.

A Paste for Epithelioma.—*Progrès médical* for February 16th ascribes the following to M. Danlos:

- R Arsenious acid. 15 grains;
- Hydrochloride of cocaine. 15 “
- Orthoform. 150 “

Stir up with a little water to a thick paste and apply to the previously freshened surface of the cancer.

For the Intractable Cough of Phthisis.—Dr. Weis-

senberg (*Presse médicale*, February 13th) employs with great success the following drops in phthisical patients in whom an ulcer of the epiglottis or a particular nervous condition produces severe accesses of cough on eating, drinking, or speaking:

- R Hydrochloride of dionine, { of each. . . . 150 grains;
- Hydrochloride of codeine, {
- Hydrochloride of cocaine. 375 “
- Valeriate of ammonium, { of each. . . . 112½ “
- Water of bitter almonds, {

M.

Fifteen drops three or four times daily on a lump of sugar, to be put far back in the mouth and allowed to dissolve slowly.

For Diarrhœa.—*Progrès médical* for January 26th gives the following:

- R Benzonaphthol,
- Bismuth salicylate,
- Bismuth benzoate, } of each. . . . 75 grains.
- Prepared chalk,
- Antipyrine,

M. To make 25 wafers. From four to five may be taken daily.

For Vomiting after Chloroform.—The *Journal of Tropical Medicine* for February 15th cites the following from *Clinica moderna*:

- R Cerium oxalate. 2 grains;
- Codeine sulphate. ⅓ grain;
- Calomel. 1 “

A Tonic Wine for the Tuberculous.—*Progrès médical* for January 26th cites the following by M. Blanc from the *Bulletin général de thérapeutique*:

- R Sodium arsenate. 1½ grains;
- *Bitter drops of Baumé. 45 “
- Cinchona wine. 3,750 “
- Coca wine, { of each. 1,875 “
- Kola wine, }
- Acid phosphate of wine. 300 “

M. A soup-spoonful to be taken after the two principal meals.

*[*Gouttes amères de Baumé*, of the French codex, is “a preparation made by macerating for eight or ten days in a closed vessel, with occasional shakings, and afterward expressing and filtering, 500 parts of grated St. Ignatius bean, 5 parts of potassium carbonate, 1 part of soot, and 1,000 parts of dilute alcohol. The Belgian pharmacopœia employs hard-coal soot.” Foster’s *Encyclopædic Medical Dictionary*. See “gutta.”]

The Treatment of Pyorrhœa Alveolaris.—*Nord*

médical for February 15th ascribes the following treatment to Dr. Bruneau, citing the *Journal de clinique et de thérapeutique*. The disease is divided into three stages.

The *first stage* is marked by a slight loosening of the gum, a grayish rim a millimetre in thickness, and a zone of livid congestion extending as far as the loosening; a purulent oozing on pressure, on waking in the morning, and absence of pain. The condition is localized about one or more teeth, around which a tartar accretion may be seen. The treatment consists of thorough cleansing of the mouth, the removal of pieces of tartar, and the application of caustic (chromic or carbolic acid, and especially the actual cautery).

Every morning a good brushing followed by a hot antiseptic lavage with

- R Chloral. 2 parts;
- Boiled water. 100 “

M.

Or:

- R Boiled water. 4,000 parts;
- Thymic acid. 3 “

M.

Then apply with a stylet, making it penetrate to the bottom of the loosened part, a piece of cotton steeped in the following solution:

- R Carbolic acid. 3 parts;
- Glycerin. 10 “
- Distilled water. 20 “

M.

Renew the antiseptic lotions after each meal. In the evening, after a fresh lavage, apply to the edges of the gums some of the following mixture:

- R Sodium bichlorate. 100 parts;
- Salol. 50 “
- Saccharin. 1 part.

M.

LEGAL INCONSISTENCIES.

THE luminaries of the law seem to extract endless satisfaction out of expressing their scorn for medical differences of opinion as occasionally exemplified on the witness stand. In our issue for February 9th we cited the opinion of a Philadelphia judge in the case of a physician whom he scored for being late in attendance at a trial in which he was cited to appear as a witness, remarking that it was better that a patient should die than that the commonwealth should be treated with contempt. In commenting on this extraordinary legal dictum we then said: "It is easily conceivable that the circumstance might occur under conditions in which no loophole of escape from the dilemma of a choice between duty to life or to the commonwealth would be forthcoming—*e. g.*, the case * * * of an obstetrician or surgeon in the midst of a confinement or an emergency operation." A curious commentary hereon is afforded by a law report in the *San Francisco Examiner*, cited in the *Sun* for March 1st. A physician of San Francisco, meeting with obstruction to his course of action in a midwifery case, finally declared concerning the patient's opposition that "if she did not quit he would quit," and eventually carried out his threat. Over an hour elapsed before another physician could be found and the obstetrical operation completed. For this breach of duty the physician was fined \$2,000. He appealed against the decision; and, in affirming the decision of the court below, the Supreme Court said, in part:

"It is the undoubted law that a physician may elect whether or not he will give his services to a case, but having accepted his employment, and entered upon the discharge of his duties, he is bound to devote to the patient his best skill and attention and to abandon the case only under one of two conditions. First, where the contract is terminated by the employer, which termina-

tion may be made immediately. Second, where it is terminated by the physician, which can only be done after due notice and an ample opportunity afforded to secure the presence of other medical attendance. * * * He can never be justified in abandoning it (a case) as did this defendant."

We certainly consider this a very just and proper interpretation of the principles involved; but if the physician "can never be justified in abandoning it (a case), as did this defendant," what becomes of the Philadelphia judge's dictum that "it is better that a patient should die than that the commonwealth should be treated with contempt"? The terms of the California decision undoubtedly uphold our contention in the article before referred to, and we feel sure that the common sense of the community will be in entire accord therewith. But the expert evidence of lawyers thus appears at times to come to loggerheads on first principles no less than that of doctors. We do not mean of lawyers acting as advocates, but of judges, whose obligation to avoidance of partisanship and to the simple elucidation of truth *per se* is just as great as that of the physician who is unfortunate enough to be in the invidious position of an expert witness.

THE EXTERMINATION OF MALARIA.

ANNOYING as the two hundred or more species of the *Culicidæ* all are, and richly deserving of suppression, it is reassuring to find that very few of them are capable of conveying malarial disease. It seems almost certain that all the species of the genus *Culex* are innocent, and perhaps but few species of the genus *Anopheles* are a source of danger. It is highly desirable that all localities where mosquitoes of any sort exist should receive the entomologist's careful attention, in order that the work of exterminating the *Anopheles* may not be needlessly made more difficult by that of destroying the *Culex*. The arduous character of the work which the entomologist will be called upon to perform in some localities is well shown by Gorham, of the anatomical laboratory of Brown University, in an article entitled Notes on Mosquitoes taken at Providence, R. I., in 1900, published in the January 15th issue of the *Journal of the Boston Society of Medical Sciences*. Speaking of *Culex pungens*, he says: "The great numbers of this species that infest the 'East Side' of Providence probably come from the old Blackstone canal, the waters of which, though loaded with impurities of all sorts, are literally filled during the summer and fall with their

larvæ. They are so abundant in parts of the canal that the color of the water is changed, and a quart jar of the water scooped up at random will have two solid inches of mosquito larvæ on the bottom."

Gorham alludes to what may prove an invaluable means of exterminating mosquitoes. He says that he had supposed, before beginning his search for their breeding-places, that every body of water would be found to contain mosquito larvæ in greater or lesser abundance, but as the quest went on he was surprised to find that in only a few of the ponds and streams near Providence were mosquitoes breeding, and he soon came to the conclusion that the presence of fish of any kind in the water was a sure sign that there were no mosquito larvæ there. We must see to it, then, that those of our ponds and streams that are not too foul for fish to flourish in are speedily stocked with our finny allies in the war of destruction to be waged against mosquitoes. In the case of those that are too foul for the purpose other measures will of course have to be taken.

Charles Sedgwick Minot, the well-known embryologist, contributes to the same number of the journal cited an article entitled Notes on Anopheles. It appears that before he became engaged in embryology Dr. Minot gave considerable attention to the study of insects, and his observations on the mosquitoes, made in 1879, are perhaps among the earliest that may be found available in the task of suppressing the *Anopheles*. Concerning the larval form of one of the species found in West Roxbury (now a part of Boston), he mentions having observed a most remarkable method of feeding. As it lay quite motionless upon the surface of the water, it would suddenly twist its neck, so that the mouth faced the sky instead of the bottom of the pond, and beat the water very rapidly with its oral appendages, thus creating a current that brought particles of floating material to its mouth. This twisting movement it was able to execute by reason of its long and slender neck. Not knowing at the time what this odd larva was, he designated it in his notes as the "head-turner," and he now suggests that name for adoption as a popular term.

Preceding the articles thus far mentioned is one by Theobald Smith, in which he treats of *Anopheles punctipennis* and *Anopheles quadrimaculatus* as they are found in the suburbs of Boston, where, however, they are few in number. Inasmuch, he says, as in our climate only tertian malarial fever prevails, we have still before us the important problem of why tropical malaria does not take root among us, and therefore that of

whether the transmitters of the three different races or species of malarial parasites are the same or specifically distinct. He lays stress on the necessity of promptly treating malarial disease in the human subject, so that *Anopheles* may find nothing to transmit, but he seems to go hardly so far as Koch, who maintains that this is the paramount means of stamping out malaria. We are encouraged to entertain the expectation that before long malarial disease will indeed be much restricted, if not altogether annihilated.

MARK TWAIN AND THE OSTEOPATHS.

OUR humorous friend, Mark Twain, whom we all appreciate, in his amusing speech at Albany in support of the claims of the osteopaths to legislative recognition, entirely misses the point at issue. He pleads for the right to experiment with his own body to his heart's content, by which he seems to mean to let others experiment with it. But this bill claims more than the right to gratify him and those who agree with him. It aims to confer State recognition upon a body of persons professing to be what they are not, namely, properly, adequately, and scientifically educated, and qualified to deal with disease in all its aspects and relations, not only to the individual, but to the community also; for, as it happens, these two aspects can never be entirely separated. Mark Twain may believe nickel to be as good in every respect as silver, and he has a perfect right to consider it so if he pleases, and even to label his own property in nickel with the word "silver"; but would he seriously (if he ever does anything seriously) uphold the propriety of stamping some one else's nickel with a sterling mark that should authoritatively proclaim it silver in the name of the government? The attempted parallelism between religious and medical liberty is not to the point. A man's religious convictions concern no one but himself; they are, moreover, matters of opinion and faith, and are not, and cannot be, matters of certainty and knowledge—for the most positive conviction is not knowledge. That alone is knowledge which is susceptible of demonstration, not only to one's own satisfaction, but by logical processes to the logical faculty in others also. Neither is his appeal to the legal status of the homœopathic and eclectic schools of medicine any more to the point; for, while therapeutic dogmas may be in the same category as religious convictions in relation to this question, therapeutics is by no means the whole of medicine. The homœopathic and eclectic

schools of medicine, of the State recognition accorded to which Mark Twain made such a point, at least train their alumni in the actual basal sciences of anatomy, physiology, and pathology, and in all their subsidiary branches of knowledge, upon acquaintance with which depends the capacity to distinguish one disease from another and to cooperate in stamping out, or at least preventing the further spread of, communicable and preventable disease. This aspect of disease is not of individual, but of collective import; and, however much the non-sectarian, the homœopath, and the eclectic may differ in regard to the more individual, and relatively less important, matter of treatment, they are at least possessed in common of the same scientific knowledge, and use the same available methods, for the protection of the community against the injuries that might accrue to its individual members from a person sick with a transmissible disease. It concerns no one but the patient (and his immediate friends, with whom he may be left to fight the question out) that he chooses to expect curative results from methods that some, perhaps the majority, of competent judges consider lacking in reasonable support. But it concerns the entire community that the man called in to a case of sickness should be so trained as to be competent to recognize the difference between a simple sore throat and diphtheria, or between a pustular skin eruption and small-pox. It may be true that it is the inalienable right of any man to experiment on himself, or to make a fool of himself in any way that he pleases; but that right does not give him the right also to imperil the welfare, and perhaps even the life, of all other persons with whom he may be unavoidably thrown into contact. A man whose house is his own has an inalienable right to do with it as he chooses. He has a right to burn it down to the ground if he likes; and so long as it is so situated that he does not thereby endanger the persons or properties of other people (as, for instance, if it is situated a mile or so from any other building) and does not, moreover, endeavor to defraud the insurance companies, probably no one would attempt to interfere with him. But let him try to burn down his house which is one of a block, and he would promptly and rightly be interfered with; not because his theoretical right to do as he chooses with his own is disputed, but because by so doing he would endanger the property of others.

The principles involved in these considerations apply with even greater force in the case of the other and yet more dangerous fanatical craze of the day, "Chris-

tian Science"—at which, by the way, Mark Twain himself had his little jibe not so very long ago.

Literary men seem of late to be specially attracted by these fads. First, it was the late Harold Frederic and Christian Science; now, Mark Twain and Osteopathy—or is it just possible that Mark has suddenly remembered the *Innocents Abroad*, and is putting his own quaint conceits into practice on the community at large and the medical profession in particular?

THE PUBLIC SPITTING NUISANCE.

A CORRESPONDENT of the *British Medical Journal* for February 23d writes from Rome to describe the measures taken in that city against this disgusting and pernicious habit. He translates the following notice, which is posted in public galleries and vehicles: "S. P. Q. R.—Spitting on the floor is prohibited. Receptacles should be kept in the place with a little water, to be changed daily, or quicklime in little pieces, renewed weekly. Breach of this regulation, under Article 22 of the Health Ordinance, is punishable by a money fine of from fifty-one to five hundred *lire* [approximately from \$10 to \$100]. The obligation is imposed in the interest of the public." The writer appears to approve of such a measure for Great Britain. We imagine that it is even more needed in the United States. It is satisfactory to note that the Metropolitan Street Railway Company of New York and the Manhattan Elevated Railway have taken the initiative by calling the attention of their passengers to the fact that the disgusting practice constitutes a misdemeanor and is punishable by a heavy fine, or imprisonment, or both. We trust that it will be carried out.

THE MORAL EFFECT OF CLOTHES.

IN our issue for December 16, 1898, we had an article on The Soldier and His Uniform, in which we said that the effect produced on the soldier affected his self-esteem, and added, in regard to recruiting: "There can be no doubt that the jaunty appearance of a soldier, whether on duty or on leave, makes the service attractive to young men who are thinking of entering it." And again, "we have nothing but contempt for 'dudishness,' but we feel convinced we are not overrating the importance of a smart uniform for the soldier."

A curious illustration of this view comes to us through the *Indian Lancet* for January 28th. It is said that when, during the siege of Mafeking, Baden-Powell applied to the principal medical officer for volunteer nurses, the doctor replied that a lot of his young women wanted first of all "to know what the kit would be like." Whereupon "B.-P.," who is an excellent artist, rapidly created a picturesque study of a pretty girl, made still

more pretty by a khaki blouse and a "B.-P." hat, with a green puggaree and a jay's wing. The physician returned next day with the remark, "You can take your pick—they are all crazy to join." Shall we not, then, admit the great moral effect of clothes, particularly in relation to *esprit-de-corps*?

MORE NEWSPAPER MEDICINE.

IN a New York daily paper, of date March 7th, appears a ludicrously inaccurate account of an operation of gastro-enterostomy, recently performed in this city, which is described as the "removing the patient's stomach, cutting away the pylorus (*sic*) and several malignant growths in its vicinity, and restoring the stomach to its former place," etc. Incidentally we are informed that Murphy's button is "so called from having been invented to suit" the case of Colonel Michael C. Murphy, commissioner of police of this city. Chicago tries, we know, to get ahead of New York at all times, but we must protest against such an unfair method of retaliation as the "conveyance" of the credit of the Murphy button from the distinguished Chicago surgeon to a—shall we say equally distinguished?—New York patient.

PUBLIC INSTRUCTION IN SANITATION IN MICHIGAN.

FOR years the Michigan State Board of Health has been noted for its industrious and well-directed efforts to teach the people the elements of the art of preventing disease. Its *Teachers' Sanitary Bulletin*, several issues of which are before us, must be one of the board's most efficient agencies, for in no other way, we conceive, can the rising generation be better imbued with the importance of sanitation and furnished with elementary information in that branch than through the medium of the school-teachers.

SCHOOL-BOOK "PHYSIOLOGY."

WE are glad to see that our excellent contemporary, the *Brooklyn Medical Journal*, takes the stand that ought long ago to have been taken by the medical profession on the absurd, fanatical, and injurious legislation which, unfortunately, is widely in force in the United States, whereby writers of text-books to be used in the public schools must inculcate what they know to be false concerning alcohol, or else suffer their books to be proscribed, and whereby the teachers are compelled to devote a certain proportion of their time to expounding false doctrine. Our legislators are too pliant in the hands of zealots.

News Items.

Society Meetings for the Coming Week:

MONDAY, *March 11th*: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynæcological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, *March 12th*: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Societies of the Counties of Rensselaer and Ulster (quarterly), N. Y.; Newark (private) and Trenton, N. J., Medical Associations; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioner's Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, *March 13th*: New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Medical Societies of the Counties of Albany and Montgomery (quarterly), N. Y.; Pittsfield, Massachusetts, Medical Association (private); Worcester, Massachusetts, District Medical Society (Worcester); Philadelphia County Medical Society.

THURSDAY, *March 14th*: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Societies of the Counties of Cayuga and Cortland (quarterly), N. Y.; South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.

FRIDAY, *March 15th*: New York Academy of Medicine (Section in Orthopædic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynæcological Society.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending March 2, 1901:

DISEASES.	Week end'g Feb. 23.		Week end'g Mar. 2.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	28	5	23	11
Scarlet Fever.....	437	24	541	30
Cerebro-spinal meningitis.	0	0	0	0
Measles.....	198	5	167	8
Diphtheria and croup.....	257	37	293	36
Small-pox.....	46	9	64	11
Tuberculosis.....	250	179	267	161

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending March 2, 1901:

- CORDEIRO, F. J. B., Surgeon. Detached from the *New Orleans* and ordered home via the *Buffalo*.
- PERSONS, R. C., Medical Inspector. Detached from duty as fleet surgeon, Asiatic Station, and ordered home to await orders.
- PICKRELL, G., Surgeon. Detached from the Cavite Naval Station and ordered to the Mare Island Navy Yard.
- ROGERS, F., Medical Inspector. Detached from recruiting duty and ordered to the Asiatic Station for duty as fleet surgeon, sailing from San Francisco, March 15th.
- RUSH, W. H., Surgeon, retired. Detached from the Pensacola Navy Yard and ordered home.
- STOKES, C. F. Surgeon. Detached from the *Buffalo* and ordered to the *New Orleans*.
- THOMPSON, J. C., Assistant Surgeon. Detached from the *Solace* and ordered home to await orders.
- WENTWORTH, A. R., Surgeon. Detached from the *Independence* and ordered to the *Solace*.

Marine-Hospital Service Health Reports:

The following cases of small-pox, cholera, and plague were reported to the surgeon-general during the week ending March 2, 1901:

Smallpox—United States.

Mobile, Alabama.....	Feb. 16-23.....	1 death.
Los Angeles, California.....	Feb. 9-16.....	1 case.
Washington, District of Co-		
lumbia.....	Feb. 2-23.....	12 cases.
Jacksonville, Florida.....	Feb. 16-23.....	3 cases.
Chicago, Illinois.....	Feb. 16-23.....	10 cases.
Delaware County, Indiana.....	Feb. 2.....	1 case.
Lawrence, Kansas.....	Feb. 8-16.....	1 case.
Wichita, Kansas.....	Feb. 16-23.....	3 cases.
Lexington, Kentucky.....	Feb. 8-23.....	3 cases.
New Orleans, Louisiana.....	Feb. 16-23.....	14 cases.
Shreveport, Louisiana.....	Feb. 16-23.....	2 cases.
Baltimore, Maryland.....	Feb. 16-23.....	1 case.
West Bay City, Michigan.....	Feb. 8-23.....	2 cases.
Minneapolis, Minnesota.....	Feb. 8-23.....	15 cases.
Winona, Minnesota.....	Feb. 16-23.....	13 cases.
St. Joseph, Missouri.....	Jan. 1-31.....	34 cases.
Omaha, Nebraska.....	Feb. 8-23.....	12 cases.
Manchester, New Hampshire.....	Feb. 16-23.....	30 cases.
Newark, New Jersey.....	Feb. 8-26.....	3 cases.
New York, New York.....	Feb. 16-23.....	43 cases.
Ashtabula, Ohio.....	Feb. 16-23.....	3 cases.
Cincinnati, Ohio.....	Feb. 13-22.....	3 cases.
Cleveland, Ohio.....	Feb. 16-23.....	48 cases.
Erie, Pennsylvania.....	Feb. 16-23.....	1 case.
Pittsburgh, Pennsylvania.....	Feb. 16-23.....	3 cases.
Steelton, Pennsylvania.....	Feb. 16-23.....	1 case.
Greenville, South Carolina.....	Feb. 16-23.....	2 cases.
Memphis, Tennessee.....	Feb. 16-23.....	21 cases.
Nashville, Tennessee.....	Feb. 16-23.....	6 cases.
Galveston, Texas.....	Feb. 16.....	123 cases.
Salt Lake City, Utah.....	Feb. 8-23.....	46 cases.
Huntington, West Virginia.....	Feb. 16-23.....	1 case.

Smallpox—Foreign and Insular.

Prague, Austria.....	Jan. 26-Feb. 9.....	17 cases.
Antwerp, Belgium.....	Jan. 26-Feb. 2.....	1 case.
Ghent, Belgium.....	Jan. 19-26.....	1 death.
Bahia, Brazil.....	Jan. 19-26.....	3 cases.
Pernambuco, Brazil.....	Dec. 17-Jan. 15.....	62 deaths.
Rio de Janeiro, Brazil.....	Dec. 16-Jan. 15.....	39 deaths.
Colombo, Ceylon.....	Jan. 6-12.....	1 case.
Guayaquil, Ecuador.....	Jan. 8-26.....	11 deaths.
Paris, France.....	Jan. 16-Feb. 9.....	32 deaths.
Bradford, England.....	Feb. 2-9.....	2 cases.
Liverpool, England.....	Feb. 2-9.....	1 case.
London, England.....	Jan. 26-Feb. 9.....	4 cases.
Newcastle-on-Tyne, England.....	Jan. 26-Feb. 2.....	7 cases.
Bombay, India.....	Jan. 13-27.....	1 death.
Calcutta, India.....	Jan. 12-26.....	9 deaths.
Karachi, India.....	Jan. 13-27.....	186 deaths.
Madras, India.....	Jan. 15.....	14 deaths.
Mexico, Mexico.....	Feb. 1-16.....	6 deaths.
Rotterdam, Netherlands.....	Feb. 8-16.....	4 deaths.
Ponce, Porto Rico.....	Feb. 1-10.....	1 case.
Moscow, Russia.....	Jan. 19-Feb. 2.....	32 cases.
Odessa, Russia.....	Jan. 26-Feb. 9.....	17 cases.
St. Petersburg, Russia.....	Jan. 26-Feb. 2.....	35 cases.
Warsaw, Russia.....	Jan. 19-26.....	1 case.
Dundee, Scotland.....	Jan. 26-Feb. 9.....	12 deaths.
Glasgow, Scotland.....	Feb. 8-15.....	17 cases.
Singapore, Straits Settlements.....	Dec. 29-Jan. 12.....	10 deaths.

Yellow Fever.

Rio de Janeiro, Brazil.....	Dec. 8-Jan. 15.....	10 deaths.
Havana, Cuba.....	Feb. 8-16.....	2 cases.
Vera Cruz, Mexico.....	Feb. 8-15.....	1 death.

Plague.

Cape Town, Africa.....	Feb. 8.....	2 cases.
Bombay, India.....	Jan. 16-29.....	837 deaths.
Calcutta, India.....	Jan. 12-26.....	89 deaths.
Madras, India.....	Jan. 19-26.....	1 death.

Marine-Hospital Service:

Official List of the Changes of Station and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Fourteen Days ending February 28, 1901:

- BERRY, T. D., Assistant Surgeon. Relieved from duty at Havana, and directed to proceed to Cienfuegos, Cuba, relieving Assistant Surgeon F. E. TROTTER.
- HARRIS, B. Y., Acting Assistant Surgeon. Granted leave of absence for ten days.
- MARSH, W. H., Acting Assistant Surgeon. Granted leave of absence for four days from February 27th.
- NYDEOER, J. A., Passed Assistant Surgeon. Upon the expiration of his present leave of absence, he will report

- at Washington for orders to proceed to Cape Charles Quarantine as inspector.
- PECKHAM, C. T., Surgeon. Granted leave of absence for twenty days, on account of sickness, from February 17th.
- PURVIANCE, GEORGE, Surgeon. Granted leave of absence for one day.
- TROTTER, F. E., Assistant Surgeon. Upon being relieved by Assistant Surgeon T. D. BERRY, he will proceed to Havana, Cuba, and report to the chief quarantine officer for duty.
- WICKES, H. W., Passed Assistant Surgeon. Granted leave of absence for thirty days from March 11th.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from February 16 to March 2, 1901:

- ASHFORD, BAILEY K., First Lieutenant and Assistant Surgeon, will proceed from Fort Slocum, N. Y., to the Presidio of San Francisco with recruits, and return to his proper station.
- BUSHNELL, GEORGE E., Major and Surgeon. The sick leave granted him is extended two months.
- EDIE, GUY L., Major and Surgeon, is ordered to temporary duty for making the medical examination of officers and enlisted men belonging to volunteer regiments, *vice* ROBERT J. GIBSON, Major and Surgeon, relieved.
- HELLER, JOSEPH M., Major and Surgeon, will proceed to Fort Myer, Virginia, for duty with the squadron of the Fifth Cavalry, now under orders to proceed to the Philippine Islands.
- HOWARD, DEANE C., Captain and Assistant Surgeon, is granted leave of absence for two months, to take effect upon his being relieved from duty at Fort Hancock, N. J., by a medical officer of the Army.
- POLHEMUS, ADRIAN S., Major and Surgeon, is detailed as a member of the board of officers to meet at Fort Leavenworth, Kansas, *vice* ROBERT N. WINN, First Lieutenant and Assistant Surgeon.
- REYNOLDS, FREDERICK P., Major and Surgeon, will proceed to Washington Barracks, D. C., for duty.
- STARK, ALEXANDER N., Major and Surgeon, will proceed to Fort McHenry, Maryland, for duty, relieving GEORGE J. NEWGARDEN, Captain and Assistant Surgeon.
- WILSON, ROY A., Acting Assistant Surgeon, will proceed to Fort Ethan Allen, Vermont, for duty with the squadron of the Fifth Cavalry.

Change of Address.—Dr. Russell Pemberton, from Richmond, Virginia, to No. 200 West Eighty-eighth Street, New York.

Osteopathy in Wisconsin.—A bill licensing osteopaths has passed the Wisconsin senate, but has been held up in the public health committee of the house assembly.

"Botanical, Magnetic and Hydropathic Physicians" sought to obtain recognition and the license to practise under a bill introduced in the Nebraska legislature, but the measure has been defeated.

In Memory of Dr. O'Reilly.—A memorial meeting in honor of the late Dr. Thomas O'Reilly was held by the St. Louis Medical Society on February 28th, a series of engrossed resolutions having been adopted for presentation to his family.

Osteopathy before the Minnesota Legislature.—Senator Horton's bill providing for a State Board of Osteopathic Examiners in Minnesota was defeated on a tie vote, the chairman voting adversely, on February 27th. On a subsequent motion the bill was allowed to retain its place on the general calendar.

A Physician Ennobled.—The Grand Cross of the Order of St. Nicholas, with the title of Court Counselor, has been bestowed upon Dr. Zambaco Pasha, of Constantinople, by the Czar of Russia, who has also ennobled

him. He is already a foreign associate of the academies of medicine of Paris and of St. Petersburg.

Philadelphia Physicians Robbed.—During the past week a thief has been visiting physicians in Philadelphia, and while their attention was directed to other callers he would pick up anything found lying loose. Dr. Moslander, of Ninth and Cooper streets, is minus a gold watch and two gold rings. Dr. Emma Richardson had the same caller, and after he had gone a case of surgical instruments was missing.

Impersonation at Medical Examinations in Ireland.—A case was recently tried in Dublin in which the defendant was proved to have in two cases impersonated candidates desiring to qualify as medical students. The defendant and another student appeared for examination at the same time and each signed the other's name to his paper. For this service the defendant received in one instance £2 and in the other £5.

Memorial to Dr. Samuel C. Busey.—Arrangements are being made by a committee representing the various scientific societies in Washington, D. C., of which the late Dr. Samuel C. Busey was a member, to hold a meeting in his memory. The societies that will participate are the Washington Academy of Sciences, the Medical Society, the Columbian Historical Society, the Anthropological Society and the Philosophical Society. The date selected is the 8th day of April, the anniversary of the graduation of Dr. Busey in medicine fifty-three years ago.

Li Hung Chang's Surgeon Returns to China.—Dr. Robert Coltman, Jr., former surgeon to Li Hung Chang and professor in the Imperial University at Peking, passed through San Francisco recently on his way back to China from Chicago, where he has been spending a much-needed vacation. He has a claim against the Chinese Government for \$35,000. Three houses that were his property were leveled to the ground by the Boxers, and everything, with the exception of the clothes on his back, was confiscated by the rioters.

The Bell Bill Amended.—At a conference held in New York city on March 2d, it was agreed to so amend the Bell bill now before the New York State legislature that the bill will only interdict the practice of osteopathy, Christian Science, etc., where it is done for pay. Mr. Bell says of the amended measure: "The bill now meets all the objections which have been made to it by the Christian Scientists and Spiritualists. They have at all the hearings on the measure argued that their religious liberty was unconstitutionally hampered by its provisions. According to the bill as it now stands, these people may minister to the sick after the pattern of Him whom they call the 'master healer,' but will not be permitted to use their religion for commercial purposes, to pose as 'latterday prophets,' while at the same time charging fees for their spiritual ministrations."

Advantage Taken of New York's Free Treatment for Hydrophobic Patients.—President Michael C. Murphy, of the New York City board of health, is trying to stop the treatment at New York's expense of persons from out of town suffering from rabies. Following the discovery that a case of small-pox which originated in Mount Vernon had been sent here to be cared for, it has

been learned that many persons thought to be suffering from hydrophobia have come for free treatment at the fine laboratory maintained by New York. This practice has resulted from doctors in other places telling patients that by pleading poverty they could obtain free treatment. At considerable expense, the board of health installed the Pasteur treatment for rabies to provide treatment for those poor residents of New York who might be unable to pay for attention at private institutions. Then the rule was that patients from outside of the city should pay a fee sufficient to cover the outlay in their cases. This rule has gradually been broken down.

A Prize for the Best Essay on the Dangers of Quackery.—The Colorado State Medical Society offers for the best essay on the dangers from quackery a prize of twenty-five dollars. The competition is open to all, but young physicians are especially requested to compete. Every essay must bear a motto, be typewritten, submitted before May 15, 1901, and be accompanied by an envelope bearing the same motto as the manuscript, with name and address of the author. The society reserves the right to claim the prize essay for publication, and others will be returned on application. All manuscripts should be addressed to the Literature Committee, Room 315, McPhee Building, Denver, Col.

[No limits appear to be placed to the length of the essay. Is this an oversight?]

Confederate Medical Officers.—The annual meeting of the Association of Medical Officers of the Army and Navy of the Confederacy will be held at Memphis, Tenn., simultaneously with the annual reunion of the United Confederate Veterans, on May 28th, 29th, and 30th. All surgeons, assistant surgeons, acting assistant surgeons, or contract physicians and hospital stewards, in the army and navy of the Confederate States, and all regular physicians who served honorably in any capacity in the Confederate States army and navy, and all regular physicians who are sons of confederate veterans, are eligible to membership, and are invited to attend and contribute reports of important cases coming under their observation, and any reminiscences worthy of preservation connected with their service in the army or navy of the confederacy. Applications for membership should be made to Dr. A. L. Elcan, Southern Express Building, Memphis, Tenn. A special rate of one cent per mile has been made for the occasion by the Southern railroads.

The Medical Society of City Hospital Alumni, St. Louis.—At the last regular meeting, on Thursday evening, the 7th inst., the following papers were read: Types of Migraine, by Dr. Frank R. Frye; Observations and Remarks on the Removal of the Gasserian Ganglion in the Cadaver, by Dr. Robert F. Amyx; and A New Non-surgical Treatment for Pelvic Inflammatory Exudates, by Dr. Hugo Ehrenfest.

The Medical Society of the Missouri Valley.—The semi-annual meeting of the Medical Society of the Missouri Valley will be held in Omaha on March 21st. This organization is composed of the physicians of the States of Missouri, Kansas, Nebraska, Iowa, and the Dakotas, and was founded in Council Bluffs, Iowa, more than thirteen years ago. Among the physicians who will read papers at the meeting in Omaha are: Dr. Jacob Geiger, Dr. O. B. Campbell, Dr. Daniel Morton, Dr. C. H. Wallace, Dr. M. F. Weymann, and Dr. S. E. Cloud. The

officers of the society are: Dr. V. L. Treynor, president, Council Bluffs; Dr. T. B. Lacey, treasurer, Council Bluffs; Dr. Charles Wood Fassett, secretary, St. Joseph.

The W. W. Keen Surgical Society, of Jefferson Medical College, Philadelphia, held its annual banquet recently in that city. In addition to the forty-eight members of the society, there were present as guests a number of physicians. Albert B. Craig was the toastmaster of the evening. Dr. Keen responded to the toast, "The W. W. Keen Surgical Society"; Professor J. C. Wilson spoke on The Borderland between Medicine and Surgery; Professor E. P. Davis on The Great Tripod; Professor Hobart A. Hare on Students Always, and Professor W. M. L. Coplin on The Student Abroad. Among the physicians present were Dr. John B. Deaver, Dr. F. X. Dercum, Dr. H. A. Wilson, Dr. Young, of Johns Hopkins University; Dr. John H. Brinton, Dr. Wilmer Krusen, Dr. Thomas G. Ashton, Dr. M. B. Tinker, Dr. George Spencer, and Dr. J. H. Gibbon.

The New York Academy of Medicine.—At the next meeting of the Section in Surgery, on Monday evening, the 11th inst., Dr. Frederick Whiting will read a paper entitled The Indications for the Ligation of the Jugular Vein in Sinus Thrombosis.

At the next meeting of the Section in Otolaryngology, on Wednesday evening, the 13th inst., the following papers will be read: Tinnitus Aurium: Its Causes and Treatment, by Dr. Thomas J. Harris; and Tympanic Vertigo Due to Obstruction in the Eustachian Tube, by Dr. William P. Brandegee. Cases will be presented and specimens and new instruments will be exhibited.

At the next meeting of the Section in Pædiatrics, on Thursday evening, the 14th inst., the following papers will be read: Interesting Experiences in an Epidemic of Typhoid Fever, Fœtal and Infantile Typhoid, Scarlatina Complicating Typhoid and *vice versa*, by Dr. J. Finley Bell, of East Hampton, N. Y.; The Pathology of Typhoid Fever, by Dr. Martha Wollstein; and The Value of the Widal Reaction, by Dr. John Lovett Morse, of Boston. Dr. A. Bassler will present an interesting case of congenital heart affection.

At the next meeting of the Section in Orthopædic Surgery, on Friday evening, the 15th inst., patients and cases will be presented as follows: Two patients illustrating the mechanical treatment of congenital club-foot and a case of funnel chest, by Dr. A. B. Judson; a case of spondylolysthesis, by Dr. Henry L. Taylor; a case of coxa vara, by Dr. W. R. Townsend; a baby with fracture of the femur and congenital dislocation of the hip, and a case of congenital dislocation of the patella, by Dr. George R. Elliott. Dr. S. A. Twinch will exhibit a modified plaster-of-Paris jacket for the treatment of cervical caries, and specimens, other apparatus, and photographs will be exhibited.

The Medical Society of the County of New York and the Commission in Lunacy.—The following preamble and resolutions, after due consideration by the *Comitia Minora*, were recommended to the society, and by it adopted at a stated meeting, held on February 25th:

Whereas, Bills are now pending in the legislature (Senate bill No. 255, Assembly No. 396) relating to the appointment and qualifications of the Commission in Lunacy, and repealing the existing provision of law which requires the president of the commission to be a physician who has had "five years' actual experience in

the care and treatment of the insane, and who has had experience in the management of institutions for the insane," therefore

Resolved, That, in the opinion of the Medical Society of the County of New York, the qualifications now required of the president of the State Commission in Lunacy are highly important, and no law should be enacted which would make possible the appointment, as president of this commission, of any person who has not had at least five years' experience in the treatment of insanity, and also some practical experience in connection with the management of institutions for the insane. In view of the fact that on the Commission of Lunacy there is only one medical member, which commission has authority to discharge any patient who in its opinion is improperly detained in any public or private institution for the insane, and which has also in large measure the control of the erection of buildings for the State hospitals for the insane and also of the administration of such hospitals and the general direction of the treatment therein, it is extremely important that the one medical member of the commission should be a thoroughly qualified and experienced expert in the treatment of insanity; and

Resolved, That a copy of these resolutions be sent to each member of the legislature and to the press.

Foreign University News.—Dr. K. Brandenburg and Dr. Joh. Burghart have been appointed to the post of *privat-docent* at Berlin.—Professor A. Jentzer has been nominated as successor to Professor Vaucher as director of obstetrical and gynæcological clinic at Geneva.—Dr. Ad. Jarisch, extraordinary professor of dermatology and syphilis at Graz, has been promoted to the regular professorship.—Dr. Adam Solowij has been appointed *privat-docent* in gynæcology and obstetrics at Lemberg.—Dr. E. Heuss has been made *privat-docent* in diseases of the skin at Zurich.

Foreign Obituary Notes.—Max Josef von Pettenkofer, M. D., professor of hygiene in the University of Munich, in a fit of temporary depression, shot himself on February 10th, at the age of eighty-three. Professor Pettenkofer, on leaving school, engaged in the study of pharmacy, which he left for the stage, but after a brief experience as an actor he took up the study of medicine, taking his doctor's degree at Munich in 1843. He was appointed extraordinary professor of pathological chemistry at Munich in 1847 and six years later became ordinary professor. In 1866 he assumed the chair of hygiene, which he occupied up to the time of his death. He was the pioneer of hygiene in Germany and has exerted a powerful influence in the advancement of sanitary science throughout the world. He received many evidences of the consideration in which he was held by his countrymen, the most marked being the Prussian *Ordre pour la Mérite*, which confers hereditary nobility upon its recipient.—Dr. Heinrich Schapero, a professor in the royal clinical institute of the royal princess Helene Pawlona, at St. Petersburg, died on January 22d at the age of forty-eight.—Dr. Ritter von Hochberger, of Carlsbad, died recently at the age of ninety-two. He was able only two years ago to take an active part in a medical congress.—Dr. Johann Natterer, a Vienna medical practitioner, whose scientific work in the domain of experimental physics—*e. g.* the liquefaction of gases—was of a quite uncommon order for a man engaged in active medical practice, died recently at the age of eighty.—Dr. Victor Pashutin,

professor of pathology in the St. Petersburg Military Medical Academy, is dead at the age of fifty-five. His researches on the physiology of the nervous system and on medical chemistry, together with his text-book on general pathology, marked him as a worthy representative of Russian medical science.

Accused Hospital Nurse Acquitted.—Jesse R. Davis, the first of the three Bellevue nurses accused of having caused the death of Louis R. Hilliard, inmate of the insane pavilion, on December 12th, has been acquitted, and it is not believed that the others will be tried.

The Fitch Hospital Closed.—At midnight on February 28th the Fitch Accident Hospital, of Buffalo, N. Y., closed its doors and went out of existence. This course was decided upon because the Charity Organization Society, which managed the hospital, found the institution too expensive. The hospital was one of the oldest accident hospitals in Buffalo.

Hospital Staff Changes.—Dr. Benjamin H. Cheney, chairman of the board of physicians and surgeons of Grace Hospital, New Haven, Conn., has resigned, together with Mrs. B. H. Cheney, chairman of the woman's board of the same institution. They are the parents of Dr. Arthur S. Cheney, head of the surgical staff in Grace Hospital, who was summarily dismissed on the charge of taking fees from a hospital patient.—Mrs. Mary V. Kimmell has resigned as superintendent of the Atlantic City (N. J.) Hospital. She has filled the position since November, 1898, and her resignation was unexpected.—Dr. Pannacci, a Roosevelt Hospital surgeon, who had refused to enter a building after a fire to attend to an injured fireman, has resigned. Ill health was given as the cause, and the surgeon's friends declare that his refusal was also based on that ground; that being subject to rheumatism, he feared to enter the water-soaked building. The dismissal of the surgeon was ordered by the hospital governors just before he resigned.

Hospital Buildings and Endowments.—The Charity Hospital of New Orleans recently received \$50,000 from a person who requested that his name be withheld from the public. The money is to be used for the erection of a home for the nurses of the institution.—Complete specifications and drawings of the new buildings to be erected for Mount Sinai Hospital in New York have just been filed. The buildings will cost, according to estimate, \$1,600,000.—F. Augustus Schermerhorn, of Lenox and New York, has presented to the Pittsfield (Mass.) House of Mercy Hospital a valuable parcel of land.—The board of directors for the Illinois Central Hospital, at Paducah, Ky., have closed a contract for a \$20,000 addition to be made to that institution.—The Boston Board of Aldermen has indorsed the bill before the Massachusetts legislature granting the sum of \$10,000 to the Carney Hospital.—Next summer Aberdeen, Neb., will have a handsome new brick and stone hospital, to be built by the managers of St. Luke's.—The Board of Estimate and Apportionment has been asked to appropriate the sum of \$10,000 to build a pavilion for the insane in connection with the Kings County Hospital in Flatbush, L. I. There are but two small wards in which to receive the insane, and it is necessary to have more space both for the male and female patients.—Two gifts have been made to Wesley Hospital, of Chicago, recently, one of

\$5,000 and the other of \$1,000. The names of the donors will be announced when the dedicatory exercises of the new buildings of Wesley are held in May.—A plot of land 99 by 100 feet, on Central Park West, has just been purchased by the Red Cross Society of New York city, and a new hospital and a training school for nurses will soon be erected there.—The new annex to the German Hospital and Dispensary on Seventy-seventh Street and Lexington Avenue, New York city, is nearing completion and will be ready for patients in June.—The wards of Washington Hospital, Washington, D. C., are very much overcrowded, and the visiting physician has asked permission of the district commissioners to refuse to accept more patients.—The Hon. Charles A. Schieren, of Brooklyn, has started a subscription for a hospital at Bristol, Va. This building has long been contemplated by the prominent men of the city, and at last is about to be realized.—The board of health of Ottawa, Ont., has decided to call for tenders for a contagious disease hospital. Plans have been submitted and a suitable site will be selected.

Births, Marriages, and Deaths.

Born.

APPLE.—In Philadelphia, on Saturday, February 23d, to Dr. W. Edson Apple, United States Army, and Mrs. Apple, a son.

STONE.—In Matanzas, Cuba, on Friday, February 22d, to Dr. John Hamilton Stone, United States Army, and Mrs. Stone, a daughter.

Married.

BALL—CLAGUE.—In St. Louis, on Tuesday, February 19th, Dr. Otto Fisher Ball and Miss Leonora Montgomery Clague.

BORLAND—MANLEY.—In St. Louis, on Monday, February 18th, Dr. W. A. Borland, of Nashville, Arkansas, and Miss Mabel Manley.

GRIFFITH—POWELL.—In Washington, on Thursday, February 21st, Dr. Wilmer E. Griffith and Miss Harriet Aldine Powell.

HART—FIFIELD.—In San Francisco, on Tuesday, February 19th, Dr. Charles Edwin Hart and Miss Louise Fifield.

HETRICK—CLAYTON.—In New York, on Saturday, February 16th, Dr. Llewellyn Hetrick and Miss Laura E. Clayton.

KISTLER—NEUWEILER.—In Allentown, Pennsylvania, on Monday, February 25th, Dr. Eugene M. Kistler and Miss Caroline Neuweiler.

SKAIFE—BRAGG.—In San Rafael, California, on Thursday, February 21st, Dr. Francis W. Skaife, of San Francisco, and Miss Ada May Bragg.

WHERRITT—BARNES.—In Kansas City, on Tuesday, February 26th, Dr. Hugh S. Wherritt, of Joplin, Missouri, and Miss Edna L. Barnes.

Died.

AIKEN.—In Savannah, on Wednesday, February 27th, Dr. William F. Aiken, in the thirty-seventh year of his age.

AMET.—In Waukegan, Illinois, on Sunday, February 24th, Dr. Charles P. Amet, in the eighty-eighth year of his age.

BEST.—In Millersburg, Kentucky, on Sunday, February 17th, Dr. I. R. Best, in the fifty-ninth year of his age.

BIXBY.—In Boston, on Wednesday, February 27th, Dr. George Holmes Bixby, in the sixty-fourth year of his age.

CHAPMAN.—In Medina, N. Y., on Wednesday, February 27th, Dr. James Chapman, in the seventy-seventh year of his age.

DITTENHOEFER.—In San Francisco, on Friday, February 22d, Dr. Matilda Dittenhoefer, in the fortieth year of her age.

FESSENDEN.—In Portland, Maine, on Thursday, February 28th, Dr. Edward A. Fessenden, in the fifty-fifth year of his age.

HANDEL.—In Onawa, Iowa, on Wednesday, February 20th, Dr. Daniel Handel.

HYDE.—In Hamilton, Bermuda, on Sunday, February 17th, Dr. Seneca T. Hyde, of Neponset, Massachusetts, in the sixty-first year of his age.

KING.—In Flat Rock, North Carolina, on Monday, February 25th, Dr. Mitchell C. King, in the eighty-fifth year of his age.

MARTEN.—In Toronto, Canada, on Monday, February 25th, Dr. H. Oake Marten.

MORROW.—In New York, on Sunday, March 3d, Lucy Slaughter Morrow, daughter of Dr. Prince A. Morrow, in the nineteenth year of her age.

SEIPLE.—In Lehighon, Pennsylvania, on Friday, March 1st, Dr. W. G. Seiple, in the fifty-fifth year of his age.

SMITH.—In Winchester, Virginia, on Tuesday, February 26th, Dr. S. John Smith, in the seventy-third year of his age.

TALMAGE.—In Waterloo, N. Y., on Saturday, February 23d, Dr. Alonzo S. Talmage, in the sixty-third year of his age.

Obituaries.

RICHARD J. DUNGLISON, M. D.,

PHILADELPHIA.

DR. RICHARD JAMES DUNGLISON died at his home in Philadelphia from dropsy and heart failure following pneumonia, on March 5th, at the age of sixty-seven. Dr. Dunglison was the son of the late Dr. Robley Dunglison, professor of institutes of medicine and medical jurisprudence in the Jefferson Medical College, and the author of *Dunglison's Medical Dictionary*. Dr. Richard J. Dunglison was educated at the University of Pennsylvania, receiving the degree of M. A. in 1855, and graduated from the Jefferson Medical College in 1856. He practised medicine for a few years in Philadelphia, but relinquished his practice for literary work, to which he devoted his life, with the exception of the period between 1862 and 1865, when he was in the Federal service as acting assistant surgeon on duty in the army hospitals in Philadelphia. His principal contributions to medical literature are *Dunglison's History of Medicine*, *The Practitioner's Reference Book*, *A Hand-book of Diagnosis, Therapeutics, and Dietetics*, *A New School Physiology and Hygiene*, and *An Elementary Physiology and Hygiene*, *The Present Treatment of Disease*. He also edited the later editions of *Dunglison's Medical Dictionary*. He translated from the French Guersant's *Surgical Diseases of Children*. He was editor of the *College and Clinical Record* from 1880 to 1895, and one of the original editors of the *Philadelphia Medical Times*. He was a frequent contributor to periodical medical literature prior to 1876, but has not written much since that time. He has at various times acted as treasurer of the Philadelphia Medical Society, corresponding secretary of the Medical Society of the State of Pennsylvania, assistant secretary and also treasurer of the American Medical Association, occupying the latter position for seventeen years; secretary-treasurer and vice-president of the American Academy of Medicine, assistant secretary of the International Medical Congress of 1876, corresponding secretary of the Centennial Medical Commission, secretary of the executive committee of the Ninth International Medical Congress, 1887, and president of the Musical Fund Society of Philadelphia for twenty-five years. For twelve years he was attending physician to the Pennsylvania Institution for the Instruction of the Blind, and to the Burd Orphan Asylum. He was also corresponding secretary of the Alumni Association of Jefferson Medical College from the date of its organization, and for many years honorary local secretary of the New Sydenham Society, of London.

Pith of Current Literature.

Medical News, March 2, 1901.

Veratrum Viride; its Value in some Conditions of Toxæmia. By Dr. A. B. Isham.—The author asserts that the physicians of the past fifteen years are practically unacquainted with the virtues of this potent medicinal agent. The most striking of all the issues proceeding from a sufficient dose of veratrum viride is the profuse skin transpiration which acts promptly in lowering the temperature when it is above the normal. The drug induces in the heart muscle a retraction or contraction, which is a conservative process in that it squeezes out from the fibrils all waste and noxious products, brings the organ down from a distended over-acting state to one working in perfect order and to the best advantage. In this way it protects the heart muscles from the pathological changes that so often accompany toxæmias. The author also points out that a reduction of the body heat to the normal, or approximately so, greatly retards the activity and multiplication of pathogenic organisms. At the same time phagocytosis continues energetically—a process of great consequence in overcoming toxæmia. *Veratrum viride* proves a most excellent remedy in the toxæmia of acute alcoholism. The action of the drug in the toxæmia accompanying peritonitis is illustrated in six cases which accompany the text.

The Treatment of Delirium Tremens by the Intravenous Infusion of Saline Solution. By Dr. James P. Warbasse.—In favor of this procedure the author submits that it increases the amount of the circulating medium in which the toxic materials are dissolved, thereby diluting the poison and bathing the nerve centres with a more attenuated solution of the same. The amount of the circulating fluid is increased above the normal, so that the excretion of fluids through all the fluid excreting channels is increased, thereby carrying off in solution much of the contained toxins. The action of the heart is improved by the filling of the relaxed vessels. These suffice to restore the physiological equilibrium and turn the balance in the favor of recovery.

Yohimbin and its Salts; a New Aphrodisiac. By Dr. Roberts Bartholow.—The experiments made on animals indicate that this drug is a central paralyzer of motility, but not of sensibility. Mendel, of Berlin, found it useful in sexual neurasthenia; but the author's results, so far, are rather negative in this respect. The dose favored by the Berlin observers ranges from one twentieth to one tenth of a grain. The author believes that its use in sexual neurasthenia, in depression of the sexual organs by age and premature debility, seems warranted by the mode of action disclosed in the experiments on animals. He also expresses the opinion that yohimbin may prove of use in albuminuria, and the fact that it has a marked effect upon the renal and genito-urinary systems indicates that it may exert an action of substitution in diseases of these organs.

Belladonna vs. Scopolia. By Dr. Reynold Webb Wilcox.

Immunization for Typhoid Fever: A Review. By Dr. H. W. McLaughlin.—The original work of Brieger, Kitasato, and Wasserman, in this connection, is referred to, and the author then comments on the recent work of Dr. A. E. Wright, of the English army. His vaccine

consists of a pure cultivation of typhoid bacilli in broth or agar-agar, and is not a serum or a lymph. The strength of the vaccine after sterilization depends upon the number and the virulence of the bacilli it contains, so that the dose varies between three tenths of a cubic centimetre and one cubic centimetre. The latter is the full dose for a man, and represents an amount which would prove fatal to a three-hundred-and-fifty gramme guinea-pig. The immunizing effect of the inoculation is prolonged for at least eighteen months. Although there is much to be hoped for in this procedure, fuller statistics are absolutely necessary, and especially the following up of the inoculated cases.

Malarial Fever, with Special Reference to the Value of Blood Examinations; Report of Cases. By Dr. Herbert Old.—This article concerns itself with the practical side of the question, the author asserting that the microscopical technique involved can be readily mastered by any one, and reporting a few cases in which the diagnosis was made only through the microscopical examination.

Is Rubeola Infection Antagonistic to Pertussis Infection? By Dr. William Byrd Young.

Complete Transposition of the Viscera. By Dr. George W. Webster.

Medical Record, March 2, 1901.

The Treatment of Rheumatic and Allied Diseases of Joints Complicated by Deformity. By Dr. Virgil P. Hibney.—The author states that it is difficult to fix upon any one form of treatment that has yielded the best result, but he commends the forcible breaking up of adhesions, when inflammatory conditions have subsided, a frequent recurrence to these operations, and the indiscriminate use of plaster of Paris. He approves emphatically of absolute immobilization to promote absorption of chronic inflammatory products. He also commends the protection of joints with a limited range of motion by apparatus within the bounds of this notion.

An Improved Method of Examining the Female Ureter, Admitting Intravesical Operations and Treatment of the Ureters. By Dr. William R. Pryor.—The author, after detailing the advantages and disadvantages of the knee-chest posture, contrasts it with his own procedure, which is as follows: The patient is put on the back in the lithotomy position, and the urethra is dilated with straight sounds to a 30 or 36 French. The obturator speculum is then introduced and the urine evacuated. In women who have flaccid abdominal walls or who have marked prolapse of the anterior vaginal wall, it is advised to pass the catheter immediately before they are placed on the table. The bladder having been emptied, the table is lowered to the requisite angle, usually about forty-five degrees. The uterus then sinks away from the pubes and drags with it that portion of the bladder which is covered by peritonæum. This, being attached also to the pubes, is straightened out. At the same time the cervix sinks away from the vulva and the base of the bladder is also straightened. The bladder assumes the shape of an open equilateral triangle with rounded corners. The advantage of this posture over the knee-chest is due chiefly to the straight lines which the vaginal segment (in which the ureteral orifices are found) and the pubic segment assume.

Some Facts Regarding Ureine. By A. F. Chase, S. A. B., and William J. Gies, Ph. D.—The authors

assert, as the result of very extensive experiments, that ureine is not a chemical individual. It is a mixture containing several of the organic substances and a considerable proportion of inorganic salts ordinarily found in normal urine. Further, its toxicity can be referred to some of these normal urinary constituents. They take issue with Dr. Moor as to uric acid being the cause of uræmia, and they refuse to accept any of his deductions regarding the biological significance of this urinary complex.

A Method of Reducing Dislocations of the Thumb. By Dr. John F. Erdmann.—This consists in applying force in such a manner that the index fingers of the operator pull the metacarpal bone in a condition of extension or abduction, while the thumbs raise and push the phalanges into a position of flexion. The author has used this method with gratifying results since 1887. A case is cited.

Tuberculosis in Prisons and Reformatories. By Dr. S. A. Knopf.

The Pupil after Death. By Dr. J. E. Courtney.—To the rule that the pupils are quite widely dilated and about equal after death, the author notes the following exceptions: (1) In persons dying of large cerebral hæmorrhage, the pupils were large on the side opposite the lesion and remained perceptibly so at autopsy ten or twelve hours after death; (2) in cases of death from paretic dementia with a general meningocerebritis and adhesions of the pia to the convolutions, the pin-point pupils seen in life were unchanged at autopsy; (3) in the condition of pachymeningitis hæmorrhagica the pupil contracted on the side of the hæmorrhage has been repeatedly found so at autopsies.

Aneurysm of the Pulmonary Artery, with Report of a Case. By Dr. B. C. Loveland.

Blunders in Caring for Parts of the Body Intended for Chemical Examination. By Edward Bartow, Ph. D.

Ischio-rectal Abscess Complicated with Gangrene and Priapism. By Dr. H. H. Haralson.

Boston Medical and Surgical Journal, February 28, 1901.

The Use and Abuse of Spectacles. By Dr. Hasket Derby.—It is the author's opinion that in hypermetropia we see glasses worn too much, in myopia probably too little. He inveighs against the highly complicated and costly lens, and he asserts that where vision in each eye is normal, whether without glasses or by the aid of the ordinary sphericals, there is little to be gained by going into the question of the existence of slight degrees of astigmatism.

Avulsion of the Finger, with a Case in which this Accident Occurred to an Infant Twenty Months Old. By Dr. George H. Monks.

Two Cases of Ligature of the Internal Jugular Vein for Infective Thrombosis of the Sigmoid Sinus Due to Purulent Otitis Media; One Recovery and One Death. By Dr. Frederick L. Jack.—The author advises that in acute cases, before ligating the vein, the purulent material in the sinus should be removed until a healthy clot is reached. After this operation, if rigors and elevation of temperature recur immediately, ligate the jugular vein and then remove the entire thrombus above and below until a free flow of blood takes place. If at the original operation no healthy clot is found, ligate immediately. In chronic cases no time should be lost in ligating the vein and completely removing the thrombus.

Case of Brain Tumor with Astereognosis. By Dr. G. L. Walton.

Operation for the Removal of a Foreign Body Impacted in the Oesophagus for more than Two Weeks. By Dr. H. H. A. Beach.

Backward Dislocation of the Ulna; Fracture of the External Condyle of the Humerus; Fracture of the Radius and Ulna Near the Wrist Joint. By Dr. H. H. A. Beach.

Retention of Urine from Obstruction by the Third Lobe of the Prostate Gland. By Dr. H. H. A. Beach.

A Series of Cases Illustrative of the Clinical Importance of Bacteriological Examinations. By Dr. R. H. Fitz.—Of these cases, three were of inflammation of the respiratory apparatus, and the examination showed, in one a pneumococcal pneumonia, in another a pneumonia from Friedländer's bacillus, while in the third the influenza bacillus was the organism concerned.

Idiopathic Dilatation of Colon; Chronic Rheumatic Arthritis; Chronic Mitral Endocarditis; Hemiplegia; Embedded Needle. By Dr. R. H. Fitz.

Operation for Gunshot Wound. By Dr. C. A. Porter.—An illustration of the possibilities of accuracy in diagnosis by means of the x-ray.

Philadelphia Medical Journal, March 2, 1901.

Three Dangerous Operations: Repair of Lacerated Cervix, Curettement, and Rapid Dilatation of the Cervix. By Dr. John B. Deaver.—The author points out the various dangers and possible contingencies that may arise in the performance of these three operations, and in a general way shows the methods to overcome them and to carry the procedures to a successful issue. The vulva should be shaved and prepared by soap and water, permanganate of potassium and oxalic acid, bichloride of mercury, and carbolic acid solution, and protected by a pad of sterile gauze; the vagina, by the use of soap and water, bichloride, and carbolic solution and iodoform gauze packing. During the operation every rule of aseptic detail must be adhered to; sterile instruments and gauze, linen, blankets, etc., and hands protected by sterile rubber gloves. The author advises, however, that these three operations should be confined to the realm of surgery, and not be classed as work which is the duty and prerogative of the general practitioner of medicine.

On the Desirability of Combined Operations in Pelvic and Abdominal Surgery. By Dr. W. P. Manton.—In the opinion of the author, in every instance, whatever is necessary should be done, whether the conditions lie within the pelvis, the abdomen, or both; and the limit of execution should be gauged only by the general condition of the patient, her behavior under the anæsthetic, and the inherent dangers of the operations to be performed. These, together with experience, skilful operating, strict asepticism, and watchful care of the patient, are the *sine qua non* of success.

Urinary Hyperacidity. A Consideration of Cases with Symptoms Suggestive of Cystitis, but with no Infection, Due to this Cause. By Dr. Thomas R. Brown.—The author dwells upon the absolute necessity of accurately diagnosing this condition. If the condition is correctly diagnosed, proper medical treatment can bring about a complete cure in the majority of cases without any local treatment whatsoever of the bladder; if, on the other hand, a wrong diagnosis is

made, and the condition is regarded as a cystitis, and treated as such, often a real infection of the bladder will be set up by the long-continued use of irrigations and local applications that are so usually employed. So far as the author is aware, the determination of urinary hyperacidity as an ætiologic factor has not been described before.

Multiple Brain Abscess Following Empyema. By Dr. Thomas A. Claytor.—This case is interesting because of its rarity. Contrary to Albutt's dictum, the author asserts that these abscesses are more likely to be multiple than single. Surgical intervention is practically useless in the case of multiple abscesses.

The Use of the Aqueous Extract of the Suprarenal Gland in Persistent Epistaxis. By Dr. Lewis S. Somers.—With this use the author's results were very encouraging, and, in any nasal pathological condition characterized by congestion and erosion of the mucous lining, they clearly indicate that the suprarenal gland possesses a still further action than that of vascular constriction, and this is shown by the rapid changes taking place in the physical condition of the parts. The author asserts that it is of great value for its local nutritional effects, and its power of acting as a pure muscle tonic.

The Biochemical Basis of Pathology. By Dr. Henry A. Bunker.—In an interesting paper the author expresses his profound faith in the future of this comparatively new field of research. The possible modifications of metabolism must be infinite, and it is in these modifications and perversions of normal biochemical relations—those of physiological sequence—that the cause of morphological change must be sought; and it is upon the recognition and understanding of the chemistry and molecular physics involved in tissue structure and in tissue maintenance, that the pathology and therapeutics of the future must be based.

Cultivation of the Aspergillus in Urine. By Dr. L. Napoleon Boston.

A New Blood-stain. By Dr. Randle C. Rosenberger.—The stain for which the author claims most satisfactory results is formulated as follows:

Saturated aqueous solution of methylene-blue.	50 cubic centimetre
Saturated aqueous solution of phloxin.	20 cubic centimetre
Alcohol (95 per cent.)	30 cubic centimetre
Water (distilled).	60 cubic centimetre

This stain is useful for blood cells, and it is a fair good one for the malarial parasite of any variety.

Journal of the American Medical Association, March 4, 1901.

Nutrition and Stimulation. By Dr. I. N. Love.—The author urges that the profession study calmly, tolerantly, and temperately the problems relating to stimulants of all kinds, but tobacco and alcohol in particular, and that they put themselves in best form for doing the best work along these lines and wielding their greater influence for good, by themselves being exemplars of temperance, self-restraint, self-denial, and correct living.

The Results of the Surgical Treatment of Inflammation of the Mastoid Process. By Dr. Edward Bradford Dench.—The author particularly emphasizes the advisability of early operation in doubtful cases. Conducted in an aseptic manner, it is absolutely free from

danger. Regarding the practice of closing a portion of the superficial wound with sutures, in order to render the recovery more rapid, his own experience demonstrates that this procedure is scarcely advisable. Recovery is quite as rapid if the entire wound is treated by the open method, and any danger of pus retention is also completely avoided. In two hundred and seventy-three cases operated upon, in not a single instance could death be attributed to the operation. The author believes that it is a warrantable procedure as a diagnostic measure in doubtful cases.

Treatment of Chronic Otorrhœa. By Dr. Frank Allport.—The author, after describing the symptoms, says that a case presenting such a picture, or even a reasonable portion of it, even if absolutely unaccompanied by mastoid or other significant symptoms, would certainly lead most progressive surgeons to unhesitatingly advise either an ossiculectomy or a radical operation. Though this may be inevitable and proper, the author cautions us not to advance too hastily; let us rather err in the direction of conservatism.

Bony Defects and Fistulæ in the External Meatus. By Dr. H. Gradle.

Aphasia with Letter-blindness, without Word-blindness, with Right Hemiplegia and Pulmonary Tuberculosis. By Dr. Guy Hinsdale.

Combined Sclerosis of Lichtheim-Putnam-Dana Type Accompanying Pernicious Anæmia. By Dr. M. H. Brown, Dr. F. W. Langdon, and Dr. D. I. Wolfstein.

Croupous Pneumonia. By Dr. J. M. Allen.—The author summarizes the therapy of pneumonia. He administers a calomel and rhubarb purge at the beginning; afterwards the alimentary canal is to be kept open with castor oil and turpentine. Three hours after the purgative has been taken, the author begins with the sodium salicylate, from ten to fifteen grains. During the exacerbation of the fever Dover's powder is given. Digitalis, trophanthus, and strychnine are given in the middle of the second stage in small doses, increasing as the heart may demand. From the fourth to the sixth day the sodium salicylate is withdrawn and a mixture of tincture of perchloride of iron, potassium iodide, quinine, and nitroglycerin is substituted. The heart tonics and stimulants must be continued in full force. Oxygen inhalations have proved of value. The patient's diet should not be restricted, unless he is jaundiced by acute chloedenitis, which is often associated with croupous pneumonia; then the diet should be restricted to milk and eggs.

Irrigation of the Colon as a Therapeutic Measure. By Dr. George J. Lochboehler.—As these irrigations act mechanically, in that the weight of the fluid draws upon the upper portion of the intestines, the author believes that they are of great value to relieve constrictions and incarcerated hernia, to remove fæcal matter, mucus, and epithelial remnants in chronic enteric catarrh and in dysentery; in fact, in all conditions where the system has been depleted or become vitiated by toxic self-infection. In these cases the normal saline solution has been given with the best results.

A Protest against the Use of Proprietary Remedies. By Dr. Daniel R. Brower.—The author expresses the hope that we may turn to a more conservative prescribing, and he protests against the impetuous rushing after new and untried remedies. He advocates the modification of the patent laws, so that the present system of

triple patenting of products made for the healing of the people may no longer be possible.

Cultivation of the Æstivo-autumnal Malarial Parasite in the Mosquito—Anopheles Quadrimaculata. By Dr. Albert Woldert.

An Original Chart of the Neuronic Architecture of the Visual Apparatus. By Dr. Louis Stricker.

Address before the New York State Assembly Committee on Public Health, in the Discussion of the Bell Bill ("Christian Science Bill") Prohibiting the Practice of Medicine by Unlicensed Practitioners. By Dr. Robert T. Morris.

Anastomosis of the Ureters with the Intestine. A Historical and Experimental Research. By Dr. Reuben Peterson.

Lancet, February 16, 1901.

An Address on Craniology. By N. C. MacNamara, F. R. C. S.—The Hunterian Oration for 1901.

The Surgery of Pregnancy and Labor Complicated with Tumors. By J. Bland-Sutton, F. R. C. S.—Lecture II. In this article the author deals with the co-existence of fibroids and pregnancy. The dangers attending pregnancy, labor, and the puerperium complicated by uterine fibroids, are illustrated by a series of actual cases. From a broad survey of the subject the author concludes that, while ovarian tumors have given more trouble than fibroids to pregnant and parturient women, yet fibroids have been far more lethal, as they frequently destroy puerperal women from sepsis.

Remarks on Agglutination by Plague Blood. By Dr. E. Klein.—All agglutination experiments must start with a good emulsion of the microbes on which the agglutinating action of blood has to be tested. Such an emulsion is easily obtained in the case of the typhoid bacillus, but with the plague bacillus it is very difficult, as the latter organism, in growing, produces a sticky, interstitial substance which binds the bacilli together into clumps. Further, bouillon cannot be used as a medium, because it has a well-marked agglutinative action on the plague bacilli. The author has found that gelatin surface cultures of plague bacilli are less viscid and sticky than agar and serum cultures, and that a good emulsion is readily obtained by shaking up a particle of the gelatin growth with physiological salt solution. When normal blood was added to such an emulsion in the proportions of 1 in 20 and 1 in 40, no agglutination took place. The addition to such an emulsion of the blood of plague-infected rats in the proportions of 1 in 20 and 1 in 40 produced well-marked agglutination in ten minutes.

Why Are Both Legs of the Same Length? By G. E. Wherry, F. R. C. S.—The practical suggestions in this article are set forth in the belief that, with all the care taken to fix and set at rest the joints and limbs in cases of injury, it is easy to neglect stimulation and encouragement of growth when active treatment is needed. The period of growth in the human subject is so prolonged that a surgeon past middle age may not hope to live to see the results of his advice.

A Case of Subacute Glanders. By Dr. J. Fawcett and W. C. C. Pakes, M. R. C. S.—The authors report a case of subacute glanders of a month's duration which ended fatally, in a man aged forty-five years. Although the patient was very ill from the start, the local manifestations of the disease were slight. They were (1)

subcutaneous swellings, (2) a few small furuncles, (3) a small abscess in the left forearm, and (4) the presence of fluid in the left knee-joint. Pure cultures of the *Bacillus mallei* were obtained from the heart-blood, the spleen, and the fluid from the knee-joint. Had it not been for the bacteriological examination the case would not have been certainly diagnosed as one of glanders.

Posterior Basic Meningitis. By Dr. H. Thursfield.—The author's article is based upon a series of seventeen cases of this affection, in twelve of which the diagnosis was verified by *post-mortem* examination. Of the remaining five, two recovered, two refused to be examined, and the fifth contracted diphtheria. In nine cases, the meningeal exudation was examined bacteriologically, and in eight an intracellular diplococcus was discovered. This diplococcus lives an average of three weeks, thus differing from Weichselbaum's diplococcus, whose vitality is of very short duration. Ten of the cases occurred in males and seven in females. Four of the patients were over three years old. Vomiting occurred first in nine cases, convulsions in four, and head retraction in three. This last is a cardinal symptom and appears sooner or later in all cases. Strabismus and nystagmus were fairly frequent and early symptoms. In thirteen cases the ophthalmoscope showed definite changes in the fundus. Vomiting and progressive emaciation were present in all cases. The diagnosis is easy in very young children; in older children the disease resembles very closely epidemic cerebro-spinal meningitis.

Primary Sarcoma of the Stomach. By Dr. W. S. Fenwick.—A diagnosis of round-celled sarcoma of the stomach may often be made by attention to the following facts: 1. The disease usually occurs before thirty-five years of age. 2. In many cases there is slight, but continuous, pyrexia accompanied by rapid and profound anæmia. Fever is absent in carcinoma. 3. Simple enlargement of the spleen is by no means infrequent; it is never met with in cancer. 4. The tonsils are apt to enlarge and the follicles upon the sides of the tongue may become swollen or ulcerated. 5. Secondary deposits in the skin occur in a notable proportion of cases. These can be excised and examined microscopically. 6. A large nodular tumor or a greatly enlarged liver is rarely met with. 7. Persistent albuminuria is common. 8. The discovery of pieces of morbid growth in the vomit renders the diagnosis certain.

The spindle-celled and myosarcomata are characterized by their slow growth, the smooth, firm, and movable tumor, the frequent absence of pain, vomiting and anorexia, and the tendency to repeated hæmorrhage. If one may judge from the morbid anatomy of the disease, the surgical treatment of sarcomata of the stomach will prove far more successful than can ever be expected in carcinomata.

Foreign Body in the Abdomen. By E. H. Ellison, M. R. C. S.—The author reports a case in which an artery forceps, accidentally left in the abdomen during an operation for hernia eight years previously, gradually worked their way out, point foremost, through the abdominal wall in the neighborhood of the umbilicus.

A Case of Cephalhæmatoma. By H. H. Borland, M. B.

Primary Carcinoma of the Ampulla of Vater, with Report of a Case Presenting some Special Features of Interest. By Dr. H. D. Rolleston.—The author reports

a case of this affection occurring in a man aged sixty-six years. Death took place from hæmorrhage into the dilated duct of Wirsung. Among the points of interest were: 1. The sudden onset of acute symptoms followed by death in eighteen hours. 2. The extremely fibrotic condition of the pancreas. 3. The absence of glycosuria or diabetes.

On the Uses of Formalin in Glycerin. By A. C. Jordan, M. B.—The author recommends the use of a forty-per-cent. solution of formic aldehyde in glycerin as an application to the throat, as a mouth-wash, as an application to the skin, and as a urethral injection. The pain produced by using watery solutions of formaldehyde is entirely avoided. Solutions of from one to four per cent. are used. In follicular amygdalitis it is a specific, and it is of great value in tonsillar diphtheria. In aphthous and parasitic stomatitis, a single thorough application often suffices to bring about a cure. Formaldehyde may be thus applied to the skin in all parasitic diseases, especially in ringworm. As a urethral injection, it causes too much pain and swelling to be recommended in all cases.

Maternal Impressions in Lower Animals. By A. Wilson, F. R. S.—The author cites the case of an antelope kid, killed in South Africa, which had an elephantine head and proboscis, while the tail was of the proboscidean, rather than of the antelope type. The author supposes the pregnant ewe to have been frightened by an elephant.

February 23, 1901.

A Quiet Effusion into the Knee-joint Occurring in Women and Young Girls. By W. H. Bennett, F. R. C. S.—The author calls attention to a condition of quiet, passive effusion into the knee-joint occurring in women and young girls, which is always associated with menstrual irregularity or uterine trouble. It rarely occurs in any other joint than the knee, and the joints of the opposite sides are usually involved at the same time but the effusion is, as a rule, much more marked on one side than on the other. There is rarely any pain unless some injury has been received. It occurs either at the time of puberty or at the climacteric. Although the joint may contain considerable fluid, it is never tense except after superadded injury. The common cause of the discovery of the condition is an injury, commonly very slight. Any error in diagnosis can usually be avoided by noticing the character of the swelling, the existence of effusion on both sides (that on the uninjured side being painless and without heat), and the coincidence of marked menstrual or uterine trouble. The primary treatment should be directed to the correction of the faulty uterine functions, with moderate exercise and massage, combined with the healthiest of outdoor lives. Treatment by splints and absolute rest should be vigorously avoided. In the absence of acute symptoms arising from injury, the condition of the knees need lead to no restriction in the exercise of an ordinary person. The author has seen some twenty cases of this affection; in no case did recovery occur while the uterine or catamenial irregularities continued and in every case their correction was followed by prompt improvement in the condition of the knee.

The Surgery of Pregnancy and Labor Complicated with Tumors. By J. Bland-Sutton, F. R. C. S.—This is the third and concluding lecture of the series, and deals with the following subjects: Pregnancy compli-

cated by cancer of the neck of the uterus; tumors of the pelvis; misplaced viscera; sequestered and quick extra-uterine foetuses.

The Diagnosis and Treatment of Abscess in Connection with the Vermiform Appendix. By R. Morrison, F. R. C. S.—The conclusions reached by the author are as follows: 1. The early diagnosis of abscess in connection with the vermiform appendix is of great importance. 2. A dangerous abscess may be present without any of the ordinary symptoms or signs of pus formation. 3. The diagnosis is based upon the history of an acute attack of appendicular inflammation and the presence of a definite tender lump. 4. The position of the appendix and the relations of the abscess may be foretold by a careful study of the tumor. 5. The diagnosis of pelvic cases in women is attended by special difficulties. Bimanual examination may be of great service. 6. Spontaneous relief and possible cure may follow the discharge of pus into the adjacent bowel. 7. An abscess, though of appendicular origin, may be remote from the appendix and may be residual. 8. Early operation is the proper treatment, and, with few exceptions, the vermiform appendix should be removed at the time that the abscess is drained. 9. The abdominal opening should be large enough to permit perfect inspection of all manipulation and the abscess should be drained from behind.

Points in the Classification and Diagnosis of some Joint Affections. By Dr. G. A. Bannatyne.—The author classifies the commoner arthritic troubles as follows: 1. Bacterial or toxic arthropathies; (a) bacterial—rheumatism, rheumatoid arthritis, gonorrhœal and scarlatinal arthritis (and probably malarial arthritis); and (b) toxic—gout and pulmonary osteo-arthropathy. 2. Nerve degenerative arthropathies, such as occur in tabes, ataxic paraplegia, etc. 3. Senile degeneration arthropathies, such as senile arthritis or malum coxæ enilis.

Malarial arthritis may be classed provisionally as bacterial, for the malarial parasite may be regarded in its actions as to all intents and purposes a bacterium.

The author discusses at length the symptoms and diagnostic points of the different varieties of arthritis.

Muscular swellings are most often due to rheumatism, small subcutaneous nodules also to rheumatism, larger ones to rheumatoid arthritis, bursal enlargements to chronic gout, rheumatoid arthritis, or rheumatism, and bony nodes to chronic gout or chronic rheumatoid arthritis.

On Protective Inoculation and Serum-therapy. By Dr. J. L. Bunch.—This article is an excellent summary of the present status of our knowledge as to the nature of immunity, and the various means for its induction. The serum-therapy of typhoid fever, diphtheria, and plague is also discussed.

Persistent Metrorrhagia. By Dr. J. I. Parsons.—In many cases of persistent hæmorrhage from the uterus the author has been able permanently to stop the bleeding by the use of the constant current, and he wishes to advocate this method of treatment in preference to the risk and mutilation involved by hysterectomy. A clay pad is placed on the wall of the abdomen just above the ribs and connected with the negative pole, while the intra-uterine electrode is connected to the positive pole. At the first application only a mild current should be used, not more than fifty milliampères. This is kept on

for from ten to fifteen minutes. The patient need not lie up during the treatment, and, except in extreme cases, may come to the doctor for treatment. The applications are made twice a week. An antiseptic vaginal douche should be used every day, morning and evening.

British Medical Journal, February 16, 1901.

Remarks on the Heart-index Interval in Aortic Regurgitation. By Dr. P. M. Chapman.—In cases of aortic regurgitation, where the aortic valves are permanently open and the ventricular cavity and the aorta are practically thrown into one, we should expect the radial pulse-wave to be synchronous with the cardiac systole. Yet Flint, Broadbent, and other observers have noted that the pulse-wave in such cases is frequently delayed—*i. e.*, the heart-index interval is prolonged. The author has succeeded in obtaining a sphygmogram from a case of aortic regurgitation which demonstrates this delay very clearly. He holds that the cardiac contraction is more of the nature of a steady push against a weight, and the resulting wave, not being created by impact, is a slowly propagated wave—that is, one of very much less velocity. Another factor is to be found in the large mass of muscle in a hypertrophied heart, which contracts more slowly, owing to the propagation of nervous impulse through its substance being more slow.

The Effects of Severe Muscular Exertion, Sudden and Prolonged, in Young Adolescents. By Dr. W. Collier.—The two commonest effects of severe muscular exertion are as follows: 1. A great strain is thrown on the air vesicles, leading to physiological emphysema, the physical signs of which are absence of the apex beat either on inspection or on palpation while at rest, absence of all superficial cardiac dulness, and a hyperresonant note on percussion above the clavicles and along the edges of the sternum. 2. A great strain is thrown upon the right side of the heart, on the right ventricle and right auricle, as passive congestion of the lung implies overdistention of the right ventricle.

Further, oft-repeated muscular effort produces hypertrophy of the left ventricle, which in turn is followed by distention of the aorta, producing incompetence of the aortic valves. The author points out how these dangers of severe muscular exertion may with a little care be avoided. He recommends the systematic examination of the hearts of all schoolboys engaged in athletic sports; that young boys should not be allowed to compete in the severer competitions at first; that the effort in every case should be preceded by a period of training and preparation; and that successful school athletes should make their athletic careers short ones. In cases of so-called "intermittent albuminuria," the author advises that all competitions involving great muscular exertion be given up.

Cases of Adult General Paralysis with Congenital Syphilis. By Dr. R. P. Smith.—The author reports two cases of adult general paralysis in which the factor of inherited syphilis outweighed in importance any other of the ordinarily accepted causes of the disease. The father of each of the patients had not only had syphilis, but had died of general paralysis, there being thus a direct inheritance of both diseases. In neither case was there any history of alcoholism or of sexual excess.

Wind Exposure and Phthisis. By Dr. C. A. Davies.—After careful investigations, covering a period of fif-

teen years, the author finds that the results obtained can in no way be considered to support the theory that strong winds are accountable for the peculiar distribution of phthisis in the Isle of Man, whatever may be the case elsewhere. When investigating the effects of wind exposure on phthisis, the sex-mortality should always be given.

Thyreoid Extract as a Remedy, with Illustrative Cases. By Dr. P. B. Smith.—The author reports three cases of various affections, where the administration of thyreoid extract was productive of great benefit. In the first case, one of inoperable carcinoma of the breast with widespread secondary infection, the administration of thyreoid extract brought about an almost complete disappearance of the carcinomatous nodules, and marked general improvement. The patient's condition grew worse again after about eight months, but she is still living, although two and a half years have elapsed since the thyreoid extract was first given. In the second case, one of general erythema of the skin, thyreoid extract brought about a cure where all other remedies had failed. In the third case, one of obesity, the patient's weight was reduced forty-two pounds within a few months by thyreoid extract. The remedy was given in the form of five-grain tablets, one three times a day.

Cerebellar Abscess Successfully Treated by Operation. With a Note on a Method of Counter-drainage Employed. By Dr. T. Barr and J. H. Nicoll, M. B.—The authors report a case of the above-mentioned affection and conclude that: (1) early operative interference in the way of discovering and subsequently draining the cavity offers the only chance of recovery in cases of intracranial pyogenic lesions; (2) the results in such cases of operative interference have been much more favorable in temporosphenoidal than in cerebellar abscess; (3) the cause of death in cerebellar abscess is, in a large majority of the cases, dropsical distention of the lateral ventricles (with oedema of the surrounding brain tissue). This ventricular dropsy appears to be the result of obstruction of the veins of Galen, produced by thrombosis originating in their lumina, or extending thence either from the superior cerebellar veins or from the straight sinus.

At the present date, two years and a half after operation, the patient remains well. For twenty-six months he has followed his occupation without the slightest return of any of his symptoms. He is still, however, deaf in the affected ear, and pulsations can be detected in the trephine area over the temporosphenoidal lobe.

Trephining in Intracranial Suppuration the Result of Fracture. By D. A. McCurdy, F. R. C. S.

A Report on Ten Cases of Poisoning by Arsenetted Hydrogen. By Dr. J. S. Clayton.—The author reports ten cases of poisoning by arsenetted hydrogen occurring in men engaged in the manufacture of zinc chloride from crude zinc oxide and hydrochloric acid. In all of the cases there was jaundice; in eight of them it was intense. In two only could it be described as slight. In nine, also, there was hæmaturia. Intense thirst and a burning pain in the chest characterized the onset and earlier stages in all the cases. Diarrhœa was troublesome in five, and all the patients suffered from profound anæmia in the later stages of the disease. The effect on the nervous system was severe in nine. In six of these the prostration and collapse of the earlier stage was very severe. One case proved fatal; there was suppression of urine toward the close, and death took place on the seventh day.

The Electrolytic Deposit of Sulphur from the Harrogate Sulphur Waters as a Therapeutic Agent. By Dr. F. W. Smith.—The conclusions reached by the author are as follows: 1. That nascent sulphur is deposited in the Harrogate sulphur water by electricity at the positive pole. 2. That the same thing takes place on the skin of patients in a sulphur electric bath under similar circumstances. 3. That in addition to the remedial effect of nascent sulphur, electricity stimulates the peripheral nerves all over the body in a sulphur bath, and thus renders the action of sulphur more rapid and efficacious in skin and gouty affections.

Amputation Mortality at the London Temperance Hospital. By Dr. W. J. Collins.—The author gives a table of 107 cases of amputation, with but two deaths. One fatal case of amputation at the hip was in a little girl in the last stages of morbus coxæ, and suffering from advanced amyloid degeneration. The other fatal case was that of a man with sarcoma of the liver and secondary growth in the ham, for which amputation at the thigh was performed. The latter was the only case in which alcohol in any form was ordered.

February 23, 1901.

Remarks on the Conclusions of the Report of the Anæsthetics Committee of the British Medical Association. By G. Eastes, M. B.—Among the conclusions reached by the above-mentioned committee are the following: Ether may be accepted as the safest routine anæsthetic, but certain circumstances may make the use of some other anæsthetic both safer and easier. No method of administration of chloroform is free from danger; this depends largely upon the administrator. Anæsthetics are more commonly associated with complications and dangers in males than in females. Excluding infancy, the dangers of anæsthesia increase *pari passu* with advancing age. Danger to life is especially likely to be incurred in early periods of the administration of anæsthetics, while the tendency to less grave complications increases directly with the duration of anæsthesia. Chloroform is most dangerous in early infancy and after thirty years of age; it is about twice as dangerous in males as in females. In conditions of good health, chloroform is the most dangerous anæsthetic; when danger occurs, in a large proportion of cases the symptoms observed are those of primary circulatory failure. Imperfect anæsthesia is the cause of many cases of danger under chloroform. Vomiting and struggling during anæsthesia, severe vomiting and circulatory depression, and grave and persistent respiratory complications, are more frequent with chloroform than with ether. Ether, where employed throughout, or preceded by nitrous oxide gas, is singularly free from danger in healthy patients. By far the most important factor in the safe administration of anæsthetics is the experience which has been acquired by the administrator.

A Criticism of the Report of the Anæsthetics Committee of the British Medical Association. By Dr. A. D. Waller.

A Preliminary Note on the Ætiological Agent in Vaccinia and Variola. By Dr. M. Funck.—The author claims to have proved experimentally the following facts: 1. Vaccinia is not a microbic disease. 2. It is caused by a protozoon easily found in all vaccine pustules and in all active vaccine. 3. The inoculation of the protozoon in a sterile emulsion reproduces in susceptible

animals all the classical symptoms of vaccinia. 4. This inoculation renders the animals refractory to subsequent inoculation with vaccine. 5. The variolous pustule contains a protozoon morphologically similar to that in the vaccine. 6. Variola and vaccinia are two identical affections; vaccinia is nothing more than an attenuated form of variola, and the immunity to small-pox which vaccination confers does not form an exception to the general laws of specific immunity.

A Preliminary Note on the Cultivation of the Microbes of Vaccinia and Variola. By Dr. S. M. Copeand.—The author has found that the microbe of vaccinia can be cultivated as follows: Collodion capsules, after being filled with beef broth and inoculated with a race of glycerinated vaccine lymph free from extraneous microbes, are sealed up and placed within the peritoneal cavity of rabbits and dogs for one or two weeks. At the end of that time, the fluid in the capsules contains zooglœa masses of bodies resembling pores, representing the resting stage of the specific microbe. The fluid is, moreover, capable of producing a typical eruption of vaccinia in the calf. The contents of similar capsules incubated outside the body remain sterile.

Liverpool School of Tropical Medicine: Yellow Fever Expedition (Abstract of Interim Report). By I. E. Durham, F. R. C. S., and W. Myers, M. B.—The authors have found a fine, small bacillus in the organs of all fatal cases of yellow fever examined by them (fourteen in all). It was found in the kidneys, spleen, lymphatic glands, and in the contents of the lower intestine. It is probable that recognition has not been previously accorded to this bacillus by reason of the difficulty with which it takes up stains (especially methylene-blue), and by reason of the difficulty of establishing growths on artificial media. The best staining reagent is carbolic fuchsine, in which the specimens are to be immersed for several hours, followed by weak acetic acid. Ten or twelve hours' immersion is necessary. Pure cultures are obtained by placing whole mesenteric glands into broth under strict hydrogen atmosphere. The authors think the evidence in favor of the biological importance of this fine, small bacillus is stronger than any that has yet been produced for any other pretended "yellow fever germ."

The Margin of Error in Bacteriological Diagnosis. By Dr. J. O. Symes.—The author calls attention to the danger of too much importance being attached to bacteriological procedures to the detriment of sound clinical observation. In cases of typhoid fever in which the clinical signs and symptoms are well marked, the absence of the agglutinative reaction does not negative a positive diagnosis. In diphtheria, the finding of the Lebs-Löffler bacillus is of value in cases presenting doubtful clinical symptoms, but is of less value when symptoms of disease are absent, or when the exact nature of the organism is doubtful. Failure to find the specific bacillus is only of value when confirmed by repeated examinations. In cases of general blood infection, a bacteriological examination is often of the greatest value for purposes both of diagnosis and prognosis. The presence of organisms in the blood is usually of the best possible omen. In a case presenting the ordinary clinical features of phthisis, the author would require a large number of negative sputum examination reports to convince him of its nontuberculous nature.

The Protection of the Observers in Cases of In-

fectious Sore Throat. By E. Waggett, M. B.—The author recommends the use of a celluloid or mica screen, to be held before the face when examining the throat in cases of diphtheria, etc.

Two Cases of Typhoid Fever, with Abscesses of the Lung and Empyema. By Dr. S. Phillips.—The author reports two fatal cases of typhoid fever, occurring in brothers aged four years and a half, and three years, respectively, in both of which death was due to pneumonia with resultant pulmonary abscesses and empyema. The necropsies showed that both patients had almost recovered from the typhoid fever, but had succumbed to the effects of septic infection.

Improved Method of Counting Red Blood Cells. By M. Mazet.

Treatment of Caries of Temporary Molars.—M. C. Martin advises the application of crowns to the children's molars which become carious, as it facilitates mastication and thus improves digestion and assimilation, besides freeing the children from pain and preventing further decay of the diseased tooth or teeth.

Presse médicale, February 2, 1901.

Varieties of Buccal Septicæmia.—M. Pierre Sebileau describes the varieties as follows: (1) lymphophlegmonous septicæmia of the cheek; (2) phlebophlegmonous septicæmia of the face, and (3) general septicæmia without specific anatomical location. This study is mainly a pathological one, although the author gives in detail the symptoms adhering to each form of inflammation of the buccal cavity.

Diabetic Coma and Intoxication by Nitrites. By M. E. Fiquet.

Gazette hebdomadaire de médecine et de chirurgie, February 3, 1901.

Symptomatology, Diagnosis, and Treatment of Acute Cancer of the Breast.—M. U. Charbonnier, in his thesis, speaks of the foudroyant form of mammary cancer. He says there are three forms of the disease: The acute carcinomatous mastitis, characterized by immense enlargement of the whole breast, discoloration of the skin with the phenomena of venous stasis, absence of pain and ulceration, inconstant adenopathy. The disease runs its course in from six to ten months. The second form is subacute and is mainly characterized by the indolence of the process and the absence of inflammatory reaction. The third type is a transition form, beginning with a small, painful growth, axillary involvement, showing frequently a dense œdema radiating from the tumor toward the glands, and sometimes undergoing ulceration. Operative extirpation seems to be an insufficient therapeutic measure in these cases, as recurrence is usually very rapid and very fatal.

Centralblatt für Gynäkologie, February 2, 1901.

Extirpation of a Right-sided Ovarian Cyst through a Left Laparotomy Wound. By Dr. Leopold Reinprecht.

A Precipitate Birth.—Dr. Wilhelm Kunze reports a case in which the umbilical cord was torn by the fall

of the child. The retraction of the vessels prevented any bleeding, and the fact that the floor upon which the child fell was of wood probably prevented serious accident to it. The mother and child made a good recovery.

Treatment of Retroplaced, Pregnant, Incarcerated Uterus.—Dr. L. Seeligmann says that the first procedure is to elevate the uterus by carrying it through one of the oblique pelvic diameters, preferably the right oblique, so that the rectum will not interfere with the manœuvre. It is accomplished by pushing the cervix backward and gently raising the fundus. A colpeurynteur filled with fluid is then to be placed behind the uterus in the same diameter as that occupied by the uterus. The colpeurynteur is to be removed in from two to four hours. It may be reintroduced if necessary.

New Method of Supporting the Perinæum.—Dr. J. Hofbauer writes of a method of supporting the perinæum with which he has had most satisfactory results. When the perinæum is fully distended, it is carefully watched to await the appearance of the anterior fontanelle. As soon as the posterior edge of it appears, the head is seized and made to rotate to about 40°, so that it shall emerge from the vulva obliquely. By this means the perinæum is saved, particularly when it has been subjected to an especially severe strain. The same method may be employed when the forceps is used. It is important that in this "anticipated external rotation," the head be allowed to engage in the vulva in the anteroposterior diameter, and be rotated only after the anterior fontanelle has presented itself.

Vratch, January 13, 1901.

Concerning Collective Investigations on Cancer. By Dr. L. L. Levschine.—Almost all authors who treat of the statistics of cancer agree that this disease is growing more and more prevalent of late. In Moscow the number of cancer cases has doubled since 1880, and the mortality from cancer in the large cities of North America has almost doubled since 1870, according to Massey. According to Heymann, this mortality is now four times greater in Prussia than it was in 1877. The interesting question for the surgeon is: What percentage of operative successes may be expected in the various forms of cancer? The author advocates the establishment of asylums for incurable cases of malignant tumors, and has succeeded in collecting three hundred thousand roubles (\$150,000) for such an institution in Moscow. The author also believes that a great deal of good may be accomplished by a collective investigation of cancer all over the world, and has worked out a series of questions to be answered by physicians for this purpose.

Cases of Poisoning with Cream Tarts in Charkoff. By Dr. P. N. Lastchenkoff.—The author discusses the subject of food poisoning in general, and describes particularly a series of cases in which the alarming symptoms were due to eating certain cream tarts purchased at a bakery in Charkoff. On September 17, 1899, two hundred persons who had eaten these tarts showed symptoms of poisoning, which, in many instances, resembled those of poisoning with arsenic or some other mineral irritant poison. Whole families, including the servants, fell victims to this poisoning, and in a girls' boarding school twenty-eight pupils were affected. From five to ten hours after eating these tarts, the patients were seized with nausea, vomiting, pain in the abdomen, and diarrhœa. In some cases there was only nausea and vomiting. In the majority of cases the symptoms were mild, and were considerably magnified by fear. When it

was discovered that all persons who had eaten of the fatal cream-nut tarts had been attacked with these symptoms, an investigation was made by the health authorities. The chemical examination of samples of these tarts showed that there were no mineral poisons of any kind. (*To be continued.*)

Concerning the Determination of the Amount of Oxidizable Substances in Water by Means of Permanganate of Potassium. (*To be continued.*)

Concerning Writer's Cramp. By Dr. I. V. Zablou-dovsky. (*Concluded.*)

American Gynecological and Obstetrical Journal, December, 1900.

Vaginal versus Abdominal Hysterectomy for Cancer of the Uterus. By Dr. H. J. Boldt.

Drainage in Abdominal Surgery. By Dr. J. W. Long.

Treatment of Inflammatory Diseases of the Uterus by Irrigation. By Dr. Frank W. Talley.—Rhinologists and pharyngologists preface their treatment of the acute and chronic inflammations of their respective mucous membranes by the careful cleansing from altered secretions with alkaline solutions. Their theories are none the less applicable to the uterus. The solution used is water, to which is added sodium bicarbonate—about a drachm to the quart—and enough carbolic acid to render it mildly antiseptic. The temperature of the solution for beginning the irrigation should be about 110° F., and this should be increased by cautiously adding hot water to the reservoir until the patient's degree of tolerance has been reached. The author has never been able to increase the temperature above 123° F. The treatment should be continued for about twelve minutes, using about one gallon of water. The effect of the application of heat and moisture is primarily to cause a vasomotor dilatation and congestion of the part. If the irrigation is persisted in, however, the dilatation of the capillaries gives way to constriction and the part becomes blanched and shriveled. The cases amenable to this form of treatment are those in which the cervical canal is patulous and readily admits of the passage of the cannula. For the last few years the results in the treatment of metritis and subinvolution by irrigation alone have been so gratifying that the author now depends upon it to the exclusion of intrauterine medication. The treatment by irrigation is preferably carried out at intervals of seventy-two hours.

Some Life-saving Measures in Obstetric Work. B. Dr. R. R. Kime.—Leaving out of the discussion instrumental deliveries, Cæsarean section, symphysiotomies etc., the author considers the most important life-saving measures: (1) Saline infusions; (2) medicinal remedies; (3) serum treatment; (4) hydrotherapy; (5) drainage. Strychnine and digitalin are well-tried remedies, to sustain life and stimulate the vital energies. The serum treatment gives promise of utility where streptococci have been demonstrated to be present. The author urges against the common practice of curetting and tapping the uterus in cases of septic infection following labor at full term. In draining the uterus, apply the same principles as are used in abscesses and septic infections in other parts of the body. Uterine drainage in puerperal infection is doubly imperative, Nature having established the precedent in normal cases to eliminate effete material, which process is often checked by the infection. Vaginal drainage is a life-saving procedure under two conditions: First, where we have pus accumu-

lation in the pelvis, threatening the life of the patient, that cannot be safely removed by abdominal section; second, in cases of infection where the inflammatory process continues to spread in spite of uterine drainage and other remedies. A few illustrative cases follow.

Left Lumbar Nephrofixation and Abdominal Myomectomy in One Sitting, with Report of Case. By Dr. Andrew J. Downes.

Proctorrhaphy: The Suspension of the Rectum for the Cure of Intractable Prolapse and Inversion of that Organ. By Dr. Charles P. Noble.

Montreal Medical Journal, December, 1900.

A Case of Conservative Cæsarean Section. By Dr. William Gardner, and Dr. David J. Evans.—If, as the authors assert, this is the first conservative Cæsarean section in Montreal, if not in the Dominion, the fact speaks volumes for the rarity of those conditions of impaired nutrition which bring about contracted pelvis. The authors believe that the sum total of suffering was much less than in normal labor in a normal condition of the birth canal.

A Case of Porro-Cæsarean Section in which Both Mother and Child were Saved. By Dr. F. A. L. Lockhart.

Cholecystitis Complicating Typhoid Fever. By Dr. W. F. Hamilton.—In the four cases reported, the diagnosis of typhoid fever was undoubted, the Widal reaction being obtained, and the ordinary clinical features determining the correctness of the diagnosis. In the matter of cholecystitis as a complication: A decided and sudden change in the temperature curve without much change in the pulse, more or less nausea and vomiting, fairly well localized abdominal pain and tenderness, icterus and the development of a tumor in the right hypochondrium, compose the clinical picture. Such features cannot fail to indicate that the gall bladder or bile ducts are involved. As Keen points out, however, many biliary complications may be wholly latent. This complication should always be regarded as a grave one; in the reported cases the mortality is twenty-five per cent.

Some Cases of Stomach Surgery—Gastrotomies, Two Cases; Gastro-enterostomies, Three Cases; Pylorotomy. By Dr. A. E. Garrow.

A Case of Carcinoma of the Pharynx with marked Involvement of the Cervical Glands in a Boy of Fourteen Years of Age. By Dr. J. M. Elder.—One would expect to find in this region either a sarcoma [of the adenoid type] or an epithelioma, but carcinoma is rare, and more especially so when the age of the patient is taken into account. But given a carcinoma, it explains the glandular involvement, together with the absence of an ulcerative condition in the primary focus.

Note on a Case of Accessory Pancreas. By Dr. Albert G. Nicholls.—The practical importance, from a pathological point of view, is that these misplaced pancreatic "rests," like other embryonic inclusions, are capable of independent growth, and thus may subsequently develop into tumors, either adenomata or carcinomata. Certain cancers of the stomach are thus not improbably due to these foetal implantations. The analogy is close with suprarenal "rests" found in the kidney.

Unusual Cases of Hernia. By Dr. A. E. Garrow.

A Case of Ichthyosis Hystrix. By Dr. John A. Hutchinson.

Report of a Fatal Case of Hernia Through the Fossa Duodeno-jejunalis. By Dr. F. G. Finley, and Dr. D. D.

Mac Taggart.—The fatal termination of the case in fifteen hours is most unusual in intestinal obstruction. The anatomical conditions described show the case to have been one of complete retroperitoneal hernia of the whole of the small intestine, with the exception of the duodenum. The obstruction, as is usually the case, was due to twisting of the bowel at the neck of the sac.

Notes from Practice in the Argentine Republic—Suprapubic Lithotomy with Suture of Bladder—No Drainage. By Dr. F. G. Corbin.

Notes on the Therapeutic Uses of Hot Air. By Dr. C. F. Martin, and Dr. D. B. Gillies.—Attention is particularly directed to the rapid relief of pain attending the hot-air treatment in sciatica, a relief that persists, and enables the patient, while taking the necessary rest in bed, to enjoy comfort and freedom from suffering.

Book Notices.

Psychopathia Sexualis, with Special Reference to Anti-pathic Sexual Instinct. A Medico-forensic Study. By Dr. R. v. KRAFFT-EBING, o. o. Professor für Psychiatrie und Nervenkrankheiten an der K. K. Universität, Wien. The only Authorized English Translation of the Tenth German Edition. Pp. xv-585. Chicago: W. T. Keener & Company, 1900.

Studies in the Psychology of Sex: The Evolution of Modesty; The Phenomena of Sexual Periodicity; Auto-erotism. By HAVELOCK ELLIS. Philadelphia, New York, Chicago: The F. A. Davis Company, Publishers, 1900.

WE have considered these two books together, because they deal only with two sides of one subject, the normal and the abnormal phases of the sexual instinct. To the medicolegal expert, whether lawyer or physician, a knowledge of the motive force underlying normal and abnormal sexual manifestations, and of the relation of the sexual emotion to other emotional states and impulses, with a study of all facts known concerning it and of the laws deducible from these facts, is an absolute necessity. To the general physician and family practitioner, for therapeutic and advisory purposes, this knowledge is also necessary. Properly applied, it will in coming ages prevent many a suicide, many a tragedy of a ruined brilliant career, such as that of one who at one time gave promise of becoming a literary genius of his age, but whose career was cut short by the morbid misdirection of his faculties, ending in a shameful imprisonment, followed but recently by death in exile, impoverished, disgraced, and abandoned.

Signs of awaking public interest in the settlement of sexual problems are, moreover, to be found in the increasing number of people in all civilized countries, who are groping for light whereby to settle questions so important to the welfare of the race, as prostitution, the transmission of venereal disease, and the regulation of marriage. These problems are not susceptible of settlement offhand, either by an intuition of Nature or by any dogmatic utterances of the religions on the one hand, or of the systems of philosophy on the other. The law of gravitation and the knowledge of electricity were not so apprehended; neither can this subject be. Such knowledge must be sought in the same way as any other branch of science, and the profound and earnest pioneers in that study deserve to have their work received with

the same consideration and respect as is awarded to the pioneer investigators in any other branch of knowledge. It is not essential that their work should have an immediately practical bearing; but it is essential that all those who are engaged in trying to grapple with the various sexual problems from a practical point of view should be imbued with the knowledge of all attainable facts—however isolated and unimportant they may appear to be—from which principles may ultimately be deduced, to place action upon a sound and philosophic basis.

At the same time, it is true that, as with the study of other regions of the morbid, so more especially with the study of this, the unequipped mind of the average layman, wanting the training to endow such studies with a proper sense of proportion, is best left undirected to them. As the limited distribution and the high price of medical works do not prevent the lay mind from dabbling widely into questions of ordinary disease, neither, we fear, will it be possible to keep it from peering into studies on the psychology of sex, and the morbid perversions of its manifestation. So long, however, as such means as can be taken are taken to lessen the danger of too free dissemination of an incomplete and prurient insight into the fields of knowledge covered in the two works under consideration, that is all that can be expected or hoped for. We are glad to note that, in the case of each book, it is stated that the sale of it is to be confined to members of the medical and legal professions. It is to be hoped that this restriction will be maintained with all the watchfulness possible. We would include even medical students in the embargo, for we hold that the general should come before the special, and that not until the student has fully equipped himself by a breadth of view and a sense of proportion as applied to the study of deviations from the line of health should he enter upon the study of their more subtle and less clearly defined forms.

With these words of cautious reserve, we wish to express our firm belief in the vast possibilities for good that underlie the careful study, by the proper persons, of the conscientious and prodigious labors of these two authors, for we consider the two works of correlative importance. Professor von Krafft-Ebing's book is, as its title implies, a pathological treatise. The fact that it has already passed through nine editions and the great importance laid upon its teachings by eminent jurists and physicians in many lands are evidence of its appreciation by those best competent to judge of its value. But little need be said specially concerning it, therefore, save to point out that the present (tenth German) edition has been considerably enlarged, mainly rewritten, and furnished with an increased number of clinical histories, which in this, as in most other fields of pathology, are most enlightening subjects of study.

While it may seem to some that there is a superfluity of such clinical histories, it must be remembered that, in such a subject as that with which Professor von Krafft-Ebing's book deals, the greater their number, the fewer are the occasions of fallacy in the deductions therefrom. In ordinary clinical histories, the wise physician, as a rule, regards subjective symptoms as comparatively untrustworthy, regarding them as side lights either to confirm or negative the results arrived at from objective examination, or to elucidate some otherwise obscure points. But the kind of clinical histories afforded by the investigation of the subject before us are necessarily almost entirely subjective, and consequently liable to

the most erroneous interpretation from the presence of the ever-varying and indefinite personal equation. It is obvious, therefore, that it is only by the collation of an enormous number of such histories that the factors which can be found in them all can be so clearly recognized as to be separable from the probably fallacious products of the personal equation.

Mr. Havelock Ellis's work, on the other hand, is in its first edition, and the subject matter is new to the student. Mr. Ellis has already done admirable work on kindred lines, and we were quite prepared, therefore, to find the conspicuous merit evidenced in the present work. The author states that pictures of gross clinical perversity (such as are collected in the book we have just been considering) "are only really instructive when they are seen in their proper perspective as the rare and ultimate extremes of a chain of phenomena which we may more profitably study nearer home." In other words, that which is normal, and the course of its evolution, should be first studied and known, before we can profitably devote attention to those deviations from the normal that we term disease.

Mr. Ellis's work is divided into three separate studies, dealing respectively with the Evolution of Modesty, the Phenomena of Sexual Periodicity, and Auto-erotism, a study of the Spontaneous Manifestations of Sexual Impulse. Of these sections the author says that "the first sketches the main outlines of a complex emotional state which is of fundamental importance in sexual psychology; the second, by bringing together evidence from widely different regions, suggests a tentative explanation of facts that are still imperfectly known; the third attempts to show that even in fields where we assume our knowledge to be adequate, a broader view of the phenomena teaches us to suspend judgment and to adopt a more cautious attitude."

In the section on the Evolution of Modesty, the author amasses a quantity of facts, covering widely different localities, races, and ages, and tending to show that what we term modesty has its roots largely in the fear of arousing disgust, and thus of lessening sexual attractiveness. This section is a treasure house of information concerning racial characteristics. It has, moreover, a wider bearing than the two others, and might be read with profit by all concerned in the study of social questions, and especially by the more advanced of our public teachers, to whom it would probably give a breadth of view that would replace the faddism and prejudice that militate against many much-needed social reforms. For this reason, we should be glad to see this essay republished separately in pamphlet form, for a less restricted circulation than it is desirable to maintain for the others.

The chapters on Sexual Periodicity tend to show that, in man as well as woman, the sexual impulse is rhythmical, though the author does not appear to think this conclusion at present demonstrable, in which we agree with him. Many correlated cycles, such as the insanity curves and those of suicide, the birth rate, etc., receive interesting consideration in this connection.

In the section on Auto-erotism, Mr. Ellis deals with the various spontaneous excitations of erotic impulse, as distinguished from those initiated by sexual attraction. The subject of masturbation is handled in a sound and practical manner, cleanly and decent, and the absurd exaggerations with which quackery and ignorance have incrustated it are brushed away. Much wholesome suggestion for counsel may be found herein.

The book further contains three appendices on The Influence of Menstruation on the Position of Women; Sexual Periodicity in Men (a remarkably frank, careful, and valuable personal study, by Mr. F. H. Perry-Coste, B. Sc.); and the Auto-erotic Factor in Religion, respectively. The last-named contains much suggestive material.

The mechanical part of the books leaves little to be desired in either case. We have no doubt, notwithstanding Mr. Ellis's misgivings in regard to the reception of his own book, that it will meet with wide and favorable recognition from the scientific world, while the work of Professor von Krafft-Ebing is already a classic.

BOOKS, ETC., RECEIVED.

International Clinics. A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pædiatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose, and Throat, and other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession throughout the World. Edited by Henry W. Cattell, A. M., M. D., Philadelphia. Volume IV. Tenth Series. Pp. vii-312. Philadelphia: J. B. Lippincott Company, 1901.

A Text-book on Practical Obstetrics. By Egbert H. Grandin, M. D., Gynæcologist to the Columbus Hospital, etc. With the Collaboration of George W. Jarman, M. D., Instructor in Gynæcology in the Medical Department of Columbia University, etc. Third Edition, Revised and Enlarged. Illustrated with Fifty-two Full-page Photographic Plates and One Hundred and Five Illustrations in the Text. Pp. xiv-511. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1901. [Price, \$4.]

Uterine Tumors: Their Pathology and Treatment. By W. Roger Williams, Fellow of the Royal College of Surgeons. Pp. xvi-359. New York: William Wood & Company, 1901.

Proceedings of the American Medico-Psychological Association at the Fifty-sixth Annual Meeting, held in Richmond, Virginia, on May 23, 24, and 25, 1900.

A System of Practical Therapeutics. Edited by Hobart Amory Hare, M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia, etc. Second Edition, Revised and largely Rewritten. Volume I. With Illustrations. Pp. 3 to 856. Philadelphia and New York: Lea Brothers & Company, 1901.

Inorganic, General, Medical, and Pharmaceutical Chemistry. Theoretical and Practical. A Text-book and Laboratory Manual containing Theoretical, Descriptive, and Technological Chemistry; Class Exercises in Chemical Equations and Mathematics; and Practical Manufacturing Processes for Five Hundred Chemical Preparations, with Explanatory Notes. By Oscar Oldberg, Pharm. D., Professor of Pharmacy, Northwestern University, Chicago, etc. In Two Volumes. Volume I, pp. xii-522. Volume II, pp. viii-655. Chicago: Chicago Medical Book Company, 1901.

Obstetric and Gynæcologic Nursing. By Edward P. Davis, A. M., M. D., Professor of Obstetrics in the Jefferson Medical College of Philadelphia, etc. Illustrated. Pp. 3 to 402. Philadelphia: W. B. Saunders & Company, 1901.

An Introduction to Physiology. By William Townsend Porter, M. D., Associate Professor of Physiology in

the Harvard Medical School. Pp. xvi-314. Cambridge, Massachusetts: The University Press.

The Johns Hopkins Hospital Reports. Volume VIII, Nos. 3 to 9. Baltimore: The Johns Hopkins Press, 1900.

Transactions of the Mississippi Valley Medical Association. Twenty-sixth Annual Session, held in Asheville, N. C., October 9, 10, and 11, 1900. Volume II.

The Ninth Annual Report of the Sheppard and Enoch Pratt Hospital for Mental and Nervous Diseases, Baltimore.

Anatomisch-klinische Vorträge aus dem Gebiete der Nervenpathologie. Von Dr. Karl Schaffer, a. o. Professor der Nervenpathologie an der Universität zu Budapest, etc. Ueber Tabes und Paralyse. Mit 5 Tafeln und 63 Abbildungen im Text. Pp. xii-296. Jena: Gustav Fischer, 1901.

Über die vom Processus vermiformis ausgehende diffuse eitrige Peritonitis und ihre chirurgische Behandlung. Von Dr. Ali Krogius, Dozenten der Chirurgie an der Universität Helsingfors (Finland). Mit 43 Kurven im Text. Pp. 240. Jena: Gustav Fischer, 1901.

Ueber Migräne. Von Dr. Alexander Spitzer, in Wien. Pp. 119. Jena: Gustav Fischer, 1901.

Moloko i Bakterii. By Dr. Stanislaw Sernowsky. Pp. 128. Warsaw: K. Kovalevsky, 1900.

Ferite Addominali e Moderno Trattamento. Pel Professor Prospero Guidone, Libero Docente di Medicina Operatoria nella R. Università di Napoli, etc. Parte I. Pp. 133. Napoli: C. G. Salvati, 1900.

New Inventions, etc.

A URETHRAL DILATOR.

BY C. JOHNSTONE IMPERATORI, M. D.,

NEW YORK.

THIS instrument suggested itself from the consideration that its spiral groove might be turned in an abnormal constriction of the urethra. By the increasing diameter of the instrument as the groove ascends, dilatation of the constriction is accomplished. The set is composed of four instruments of varying sizes. They are all seven inches long, from olive point to handle, but not including it. A description of one of the instruments will suffice.

The general shape of the instrument is that of a grooved cone, increasing regularly in size from the tip to the handle.

Each instrument increases in diameter three millimetres to the inch, and every three eighths of an inch there is a complete turn of the groove.

The olive point is tunneled so that in cases of stricture of small calibre the instrument may be turned on a filiform.

Uses.—1. As a meatus dilator.

2. As a dilator to the urethra, preliminarily to passing the regular curved sound. This instrument, through its conical shape, gradually dilates the anterior portion of the urethra, thus making it easier to pass the regular curved sound.

3. As a dilator to those strictures of the anterior portion of the urethra situated a few inches inside the meatus.

4. In small strictures—those of a size from six to fifteen, French gauge, situated at the bulbomembranous

junction. This instrument may be used as a dilator before passing the regular curved sound, and in cases of very small constrictions it may be turned on a filiform.

After introducing it within the meatus for an inch or so, by simply holding the penis perpendicularly to the

DR. IMPERATORI'S NEW INVENTION.

body, with the patient in the recumbent position, the instrument insinuates itself by turning on its long axis. The different sizes of the instruments are appended:

No. I.—At olive point, 6 French; at handle, 24 French.

No. II.—At olive point, 9 French; at handle, 27 French.

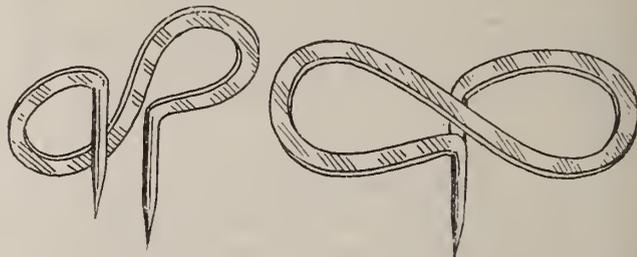

No. III.—At olive point, 12 French; at handle, 30 French.

No. IV.—At olive point, 15 French; at handle, 33 French.

Although the straight sound may be used somewhat to the same extent, yet this instrument has a greater variety of uses than the former. Two of these instruments will suffice to do the same work that a set of straight sounds will do, and they can be used in places where the latter cannot.

28 OLIVER STREET.

“A figure-of-eight piece of wire having two ends turned at right angles to the plane of base and the ends sharpened. The base is flattened and the two prongs extend one half to five eighths of an inch up from the base, perpendicular to it and parallel to each other. These two are about one fourth of an inch apart. In applying a bandage, say a recurrent of the scalp, after making one turn around the head to fix the bandage

place one pin on the inion and one just above the siniput; this will enable the surgeon, by pressing the bandage down over the extending prongs and returning over them, to apply this bandage alone and with a single-headed roller bandage. After enough has been put on, separate the prongs and turn down against the head, making, if desired, one turn around to hold them down and protect the points. This pin will work in any spica, figure-of-eight, or recurrent, as of a stump, absolutely preventing slipping at the point of application.”

Miscellany.

Fæcal Impaction.—Dr. Samuel G. Gant (*Post-Graduate*, January), in a paper read before the New York Post-Graduate Clinical Society, said that of fæcal accumulations sixty per cent. would be found in the rectum, fifteen per cent. in the sigmoid, ten per cent. in the cæcum, and the remainder in other portions of the colon. Impaction occurred more frequently in women than in men, and the older the persons the more likely were they to suffer from this affection. No age was exempt, cases having been recorded from infancy to seventy years and more. This condition might properly be divided into *acute* and *chronic*.

The most frequent causes of coprostasis were intestinal atony, paralytic affections (locomotor ataxia), large enemata, mineral drugs showing a tendency to accumulate, painful ailments about the anus (fissure), and irregular habits. In children it might result from congenital narrowing of the anus or rectum, and in adults from adhesions following a surgical operation or typhoid fever, stricture, carcinoma, or tumor in a neighboring organ. The quantity and quality of the food taken sometimes became an ætiologic factor in impaction. This was thoroughly demonstrated during the Irish famine in 1846, when fæcal accumulations were frequently caused by eating the husks of potatoes. Again, it had been shown by Monro that the people of Scotland were frequently and similarly affected as a result of eating large quantities of coarse oatmeal. A mass might have for its starting point a plum, cherry, or gall-stone, around which the fæces collect like the snow on a snowball. Houston's valves, when large, thickened, and rigid, might cause impaction.

The symptoms varied, depending upon the cause,

A SIMPLE DEVICE FOR SECURING BANDAGES.

By the courtesy of the editor of the *Journal of the American Medical Association*, we are enabled to reproduce an illustration and description of the following simple device for securing bandages, invented, and first described in the issue of that journal for February 16th, by Dr. George D. McLean, of Nashville, Tenn.

Dr. McLean describes the invention as follows:

size, consistence, and location of the impacted mass. In the beginning, there was constipation; later, constipation alternating with diarrhoea, and finally a diarrhoea of the most annoying and persistent kind. Because liquid faeces were being discharged around or through the faecal tumor, the patient's real ailment was frequently not suspected by patient or physician. In some cases the movements had a vile odor. These sufferers were nervous, despondent, and restless, had a muddy complexion, disagreeable breath, indigestion, barking cough, morning vomiting, cold feet, night-sweats (Allingham), thirst, loss of appetite, dizziness, sometimes jaundice, albuminuria, seminal emissions, varicocele, frequent micturition, sphincteric spasm, nipple-shaped anus (Allingham), and inflamed rectal mucosa. The pain from a faecal impaction was local and interrupted when small, but became continuous and disseminated as it grew larger. The mass produced a sensation of weight and fulness in the rectum, frequent and prolonged straining and bearing-down pains similar to those experienced during labor. Pain was not confined to the anal region, being frequently reflected to the abdomen, back, neighboring organs, and down the limbs, caused by pressure on the sciatic nerves. In persons suffering from impaction and faecal toxæmia the temperature was irregular, the pulse small and weak, and respiration difficult. They had a troubled expression, were anæmic, and occasionally completely collapsed from exhaustion. There might be local or general peritonitis, ulceration, perforation, and faecal vomiting in extreme cases, due to pressure and occlusion.

The length of time one could live without defæcation had long been the subject of debate, and still remained in doubt. Cases had been recorded where complete occlusion from coprostasis had existed for from one week to more than six months. The author has treated several cases due to stricture in persons who had not had an evacuation in from two weeks to two and three months, and yet some of them were fairly comfortable and did not seem to worry.

Coprostasis was the most frequent cause of *paralytic ileus*; the collected faeces prevented the downward peristaltic action, interfered with proper nutrition and the nervous supply of the intestine, and resulted in contraction of the bowel below the obstruction. Another serious and frequent sequela of large faecal accumulations was *dilatation of the colon*. The bowel sometimes assumed enormous proportions. Chronic constipation accompanied by impaction was always an important ætiologic factor in *chlorosis*. The anæmic condition of the blood was brought about as a result of a general *faecal toxæmia*. Hence the importance of teaching young girls to be regular in going to stool. This toxæmia produced a depressing effect upon the mind, and many of these sufferers did not take any interest in business, sought seclusion, and not a few had suicidal tendencies. In extreme cases, it had been known to produce temporary *mania*, and in young children symptoms simulating *cerebrospinal meningitis*. Self-infection from faecal accumulation had induced hyperæmia and œdema of the brain, congestion of the lungs and acute parenchymatous degeneration of the heart, kidneys, and lungs (Von Sölder).

Faecal impaction was less difficult to diagnosticate than other varieties of intestinal occlusion, yet the task was not always an easy one. When a hard, large faecal mass uncovered by mucous membrane was situated in the lower rectum, a digital examination quickly revealed its nature, but when it was partially covered by the mucosa, or located in the sigmoid flexure or colon, it was

often perplexing to make a positive diagnosis. It must be borne in mind that tumors of the intestine, bladder, vagina, uterus, tubes, ovaries, and prostate sometimes caused intestinal occlusion and a long train of symptoms similar to those caused by coprostasis. When the accumulation was in the rectum it was frequently mistaken by the experienced finger for carcinoma, because the mass pushed the mucous membrane down in front of it, giving to the touch a sensation similar to that of submucous cancer. The following points should be observed when distinguishing between these two conditions:

FÆCAL IMPACTION.	CARCINOMA.
1. Single, large, firm and globular in shape; or numerous, small, hard and nodular.	Two or more dense, rounded tumors.
2. Usually not covered by mucous membrane.	Covered by a mucous membrane except when ulcerated.
3. Occupies lumen of the bowel.	Projects into the calibre of the intestine.
4. Of doughy consistence and indentable.	Hard and non-indentable.
5. Not attached.	Attached.
6. Movable.	Non-movable or slightly so.
7. Occurs at any age.	In middle life and old age.
8. No cachexia.	Cachexia.
9. Odorless.	Offensive odor.
10. Comes on suddenly.	Slowly.
11. No previous history of pain or hæmorrhages.	Pain always, hæmorrhages frequently.
12. Not accompanied by discharge of mucous or jelly-like stools.	Free discharge of mucus and sometimes of jelly-like evacuations.

Symptoms common to both impaction and carcinoma were constipation in the beginning, diarrhoea later, straining frequent micturition, tumor, and reflected pains.

Faecal impaction could be distinguished from gallstone, enterolith, and pancreatic obstruction by the doughy feel and the large size of the tumor. When a tumor presented in the sigmoid or colon, causing dangerous symptoms of occlusion, and its nature was not apparent after getting the history and making a thorough examination by means of palpation and the colon tubes, the abdomen, intestine, or both, should be opened without delay, when an accurate diagnosis could be made. The rectum and vagina should be examined in all cases of constipation and obstipation in search for an impaction.

As to treatment, when the accumulation was small, not too dense, and was located in the lower rectum, it could always be softened and evacuated by frequent copious enemata of warm soap suds containing oil and glycerin. The following was a very satisfactory combination:

R Soap suds 1 pint;
 Castor oil 1 ounce;
 Glycerin 2 ounces.

M.

Inject into the rectum every two hours, to be retained as long as possible.

If the mass had been in the rectum for some time, was large, round, or hard and nodular, more radical measures were indicated, for in such cases the tumor was covered with a slimy mucus, and water could not permeate it. It was necessary to break up the accumulation into small particles, when irrigation would enable the patient to evacuate them. This could be done with the fingers, a spoon handle, or with rectal forceps. When the mass had been present a considerable time, causing dangerous symptoms of occlusion, the sphincter muscle should be divulsed under general anæsthesia, and

the tumor delivered at once, whole or in sections. When located in the sigmoid and colon, a copious injection of the formula previously named should be thrown high into the bowel by means of the long rubber colon tube. Massage was a valuable agent in obstinate cases, and when practised in an intelligent manner, fecal tumors in any part of the intestine might be dislodged, broken up, and pushed downward until they could be removed with the finger or washed out with enemata. Now and then all palliative measures failed and it became necessary to open the abdomen and do a sigmoidotomy or a colotomy, and deliver the mass when possible. When the impaction was caused by a stricture or tumor which could not be removed, a permanent artificial anus should be established, adhesions should be broken up, and the wounds in both the intestine and abdomen should be closed immediately. Purgatives were always contra-indicated in these cases because the obstruction is purely mechanical.

The author publishes a tabular analysis of forty-six cases that had come under his own care.

The Death Rate of New York State.—The number of deaths from all causes reported for the year to the New York State Board of Health is 128,468. This exceeds the mortality of 1899 by 6,647 and the average of the past five years by 8,000. Besides these reported deaths, there were 1,600 returned too late for report, making the death rate for the year 18.5. The infant mortality was 4,000 greater than last year, but the percentage of deaths under five years is the average of past years. Typhoid fever was unusually prevalent in the autumn, causing 1,948 deaths, 350 above the average. Measles prevailed to excess in all parts of the State, the 1,333 deaths being 300 above the average. Scarlet fever was less than usually prevalent. Diphtheria had a mortality 500 below the average. Small-pox was brought from outside to seventeen places during the first half of the year, without spread. From August to November the State was free from it; then a traveling minstrel troupe left it at three localities in the eastern part of the State, whence it spread. Of fourteen deaths, four have occurred outside New York City. The grippe epidemic of the year was unusually severe, and probably added 1,500 to the number of deaths.

Milk Food Forbidden in China.—The *Indian Lancet* for January 21st gives the following condensation of a proclamation in the *Loo Chow Herald*:

"Man should not rob animals of their own proper food; and, of all animals, the cow is the most valuable to man. The sellers of milk blacken their souls for gain; but those who drink milk do so in the foolish belief that it is good for them. Before taking any medicine, we should carefully investigate its properties, and who does so in the case of milk? Milk is the natural food of babes and of young animals; but when adults drink it, do they not thereby endanger the life of the suckling calf, and arouse bitter resentment in the souls of the calf and its mother? Beasts have not the power of speech, and so cannot tell men that by drinking cow's milk they will become like quadrupeds. If men must have a strengthening draught, there are a thousand better things than milk, so why select that? Besides, the term of life is fore-ordained and it cannot be prolonged by drinking milk. Everyone who reads this warning is especially enjoined to abstain from milk in the future. Children whose parents will not allow them to drink milk will not be stunted in growth, but will have their

lives prolonged and be immune in epidemics. So it is proclaimed in the Hall of Good Counsel."

Nerium Oleander.—In reference to our Therapeutical Note on *Nerium oleander* in our issue for February 23d, attention is called to a case of poisoning by this drug, upon which we commented in our issue for July 28, 1898.

A Wise Bishop.—*Merck's Archives* for January, citing the *Carlisle Journal* (England), says that at the annual meeting of the branch of the Royal Society for the Prevention of Cruelty to Animals, held at Carlisle recently under the presidency of the Bishop of Barrow, Miss Lunsden, late warden of University Hall, St. Andrews, who, it is understood, attended the meeting as the representative of the parent society, made an attack on the employment of experiments on animals in medical research. After alluding to such practices as the docking of horses' tails and the cutting of dogs' ears, she stated that vivisection was the darkest cruelty of all, and was proceeding to give at large her views on vivisection when she was interrupted by the chairman. Bishop Ware, in interposing, said great benefits had been done to mankind through experiments properly conducted. The society was not a society formed to take proceedings in regard to properly conducted scientific experiments, but to stop needless cruelty to animals. He held such a strong feeling in regard to the benefits to mankind due to vivisection properly conducted that he could not take the chair at a meeting where views were expounded such as they had now heard.

Twins Born in Different States.—Twins are always setting both Nature and conventionality at defiance. Only recently we told of twins who managed to be born in different centuries; now the *Union and Advertiser*, of Rochester, N. Y., tells us that while a lady of Portland, Ore., was traveling on a train toward Spokane, Wash., the other day, she gave birth to twins. The elder, a boy, was born in Oregon, and the other, a girl, in the State of Washington an hour later.

Freckling and Tuberculosis.—The *Medical Age* for January 10th cites *The Polyclinic* for December, 1900, as drawing attention to the fact that it is well recognized that different persons are liable to freckle with very different degrees of severity, and it has been suspected that a remarkable proneness to freckle is often coincident with tendency to scrofula or tuberculosis. It is most certain that such proneness is associated with the temperament of the individual as shown by color of eyes and hair. Freckles are, as a rule, conspicuous only in the clear skins of children and young persons. In adults they are either not often present or are comparatively inconspicuous. An observation of some interest has, however, recently been made, that they are liable to return in senile periods and to assume infective characters.

The Effect of a Grazing Bullet Wound.—Mr. A. Horman, M. R. C. S. (*Intercolonial Medical Journal*, December 20, 1900), in an article on Surgical Experiences in South Africa, says:

"It may be of some interest, from a medico-legal point, to notice the effect of a grazing wound. They give an appearance as if the skin had been burnt by a hot iron rod laid upon the skin; this is due to the removal of the superficial epidermis, exposing the true skin, which becomes brown after a few hours."

Original Communications.

CONGENITAL DISLOCATION OF THE SHOULDER, WITH REPORT OF TWO CASES OF DISLOCATION POSTERIORLY.*

By DANIEL W. MARSTON, M. D.,

NEW YORK,

INSTRUCTOR IN ORTHOPÆDIC SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; VISITING SURGEON TO THE RANDALL'S ISLAND HOSPITAL.

THE recent publication of a few contributions upon the pathology and diagnosis of congenital dislocation of the shoulder is an interesting phase of modern ortho-

out operation, and, since 1895, a few other surgeons, as Eve, Stimson, Schede, Souchon, and Stone, have reported cases, but the literature is still very meagre, and exhaustive research fails to find hardly more than brief mention of this interesting deformity.

My interest in the subject was first aroused when an opportunity to make some personal observations offered itself in two cases referred to me at the orthopædic department of the New York Post-graduate Medical School and Hospital, quite recently, by my colleague, Dr. Hendle, of Alexander Avenue, New York.

Smith's descriptions of the conditions found in his cases have often been quoted, but are now, in view of recent operative experiences, considered erroneous and

FIG. 1.—One of Scudder's cases, showing the aspect posteriorly of the deformed shoulder.

FIG. 2.—One of Scudder's cases. Note the almost exact similarity of position of the affected arm in this case and in those of Phelps and Marston.

FIG. 3.—One of Scudder's cases, in which he believes the deformity was due to non-development.

pædic surgery. Very few writers in all of the many textbooks and elaborate systems of surgery have mentioned this subject, or, if they have done so, they have, with the exception of Stimson's latest edition, passed lightly over the important points of ætiology and treatment.

Every surgeon is familiar with *old and irreducible* dislocations of this joint, and much has been written about the treatment for such cases. Regarding the congenital variety, however, it is altogether different, for, although R. W. Smith had, as early as 1839, written briefly of the pathology of this condition, the first detailed report of an operation for the relief of this deformity was published only five years ago, and then by Phelps, of New York. Küster had operated once previously, but had written nothing of the operation, and so had Post, who had likewise neglected to record what was done in the operation. In 1890 Scudder reported two cases with-

misleading. In his case of double subcoracoid dislocation, he says: "There existed on the left side scarcely any trace of an articulating surface in the situation which the glenoid cavity occupies in the normal state; but there had been formed upon the costal surface of the scapula a socket of a glenoid shape measuring about an inch and a half in its vertical direction, and an inch and a quarter transversely. It reached upward to the under surface of the coracoid process, from which the head of the humerus was merely separated by the capsular ligament."

"The head of the humerus was of an oval shape, its long axis corresponding with the shaft of the bone. The oval shape was principally due to the deficiency of its posterior part, and there existed between the greater tubercle and the margin of the head of the bone where the investing cartilage terminated a broad, shallow depression, corresponding to the edge which separated the normal from the abnormal portion of the glenoid cavity.

*Read before the Medical Society of New York, January 29, 1901.

FIG. 4.—One of the author's cases before operation.

The shaft of the humerus was small and seemingly atrophied."

Stimson has written that this deformity is occasioned by irregular development of the joint, and, secondly, may be the late result of a paralysis antedating birth or caused during delivery. Scudder reports three cases and agrees in the main with Smith. He lays stress upon the fact that in each of his cases the clavicle and scapula on the affected side were undeveloped. It is largely on this that he bases his belief that these cases are congenital misplacements of the head of the humerus, due to congenital arrest of development. He admits that in certain exceptional cases pathological changes in some other constituent of the joint may be a factor in causing a dislocation, or there may be present a mechanical factor acting *in utero*. It is noteworthy in this connection that these views of non-development as an important ætiological factor in these cases were, with the exception of R. W. Smith's *post-mortem* work, based entirely upon merely ante-operative examinations of the subject, and were not confirmed by exploratory incision. Directly opposed to these theories is the description of the pathological condition given by Phelps in the report

of his first case, operated upon in 1895, and in subsequent reports of others since then, in which he has thoroughly explored the joint and obtained excellent functional results following operation.

In Phelps's first case the patient was eight years old. The deformity had existed since birth. It was impossible for him to put his hand to his mouth, and the arm was rotated inward, turning the palm of the hand backward. The operation was performed at the private sanitarium of Dr. A. Palmer Dudley, on Madison Avenue, Dr. Dudley and Dr. Plimpton assisting. In examining the glenoid cavity with his finger in the wound, Phelps found the posterior border of the cavity had been broken away and the detached fragment was attached to the capsule. Phelps has, moreover, found the fragment of the glenoid cavity in two of his other cases operated upon.

Certainly the old adage that "seeing is believing" should hold good in careful intra-articular examination of joints.

Ordinary manipulation and outward appearances of the joint do not in these cases give sufficient evidence on which to decide whether the dislocation is due to

FIG. 5.—One of Marston's cases. Note the position of the right arm, as described in the text.

FIG. 6.—One of the author's cases before operation.

traumatism or to non-development. To my mind, the fact that in three of his cases Phelps has found the fragment of the posterior border of the acetabulum imbedded in the capsule is conclusive that, in the cases under consideration at least, the deformity was undeniably caused by traumatism.

Particularly interesting at this point is reference to the similarity in attitude between Scudder's cases, which were not operated upon, and those of Phelps, in which he found the fractured border of the glenoid cavity. The position of the shoulders is so nearly identical as to show conclusively that nothing less than an accurate radiograph or an intra-articular examination could suffice to establish a diagnosis.

It is in view of these considerations, and all that I can find in the literature, that I advocate the belief of Phelps, that these dislocations, subcoracoid, or subspinous, are due:

- I. To traumatism, either at birth or *in utero*.
- II. To some prenatal diseased condition of the joint, *e. g.*, tuberculosis or osteomyelitis *in utero*.

The majority of these cases can be traced to a difficult delivery, and more than a few of the heretofore supposed cases of obstetrical paralysis are undoubtedly instances

of traumatic dislocation at birth, with the paralysis as a coincident complication due to the same causes as produced the dislocation; the finger of the accoucheur in the axilla, or the too forcible use of the vectis, for example. The paralysis, I contend, is not a primary ætiological factor of the dislocation. Were this the case, as many assert, the dislocation would more often be anterior, rather than subspinous, for the contraction of the pectoral muscles, which are the stronger set, would certainly draw the humeral head downward and forward. *The theory of non-development is further confuted by the six autopsies of Stone, of Boston, performed on infants with this deformity, in which he found no evidences of faulty development in any case.*

The diagnosis in this deformity is easily made. Careful manipulation and palpation enable the examiner to discover the head of the bone. If it is in proper articulation with the glenoid cavity no dislocation exists, and any paralysis present is usually a true obstetrical paralysis. If the head of the humerus can be distinctly rotated in the axilla, or outside of the glenoid surface, the

FIG. 7.—Notice the similarity of the attitude in this (Marston's) case and in one of the cases (of Phelps's) in which a fragment of the glenoid border was found attached to the capsule.

diagnosis of dislocation is positive. Scudder aptly remarks that in cases due to maldevelopment there is likely to be a difference of development between all the bones of that extremity and its normal mate.

The symptoms of the condition in my own two cases

FIG. 8.—Compare the position of the right arm with the picture of the same case made prior to the operation.

are unmistakable. The position of the arms is in each case characteristic. The affected arm hangs at the side of the body, well rotated inward. The elbow is a little flexed. The forearm is pronated, so that the palm faces backward and outward and the wrist and fingers are flexed. The flexion and abduction of the arm are probably occasioned by the impinging of the head of the humerus beneath and against the spinous process of the scapula in the glenoid cavity. The rotation of the whole arm inward is due to habitual use of the limb in this unnatural position; to the anatomical relations of the parts, and to the contraction of the pectoralis major muscle.

In the treatment of these shoulders it should be the aim of the surgeon to reduce the deformity and to secure a useful joint. The means employed may be me-

chanical and operative. In one of the series treated by Phelps, assisted by Plimpton, the dislocation, which was in an infant three months of age, was reduced by manipulation. Gaillard, quoted by Stimson, reports a similar case. "Four times in the course of a week he made horizontal traction on the arm by means of a weight of sixteen pounds, continued for fifteen or twenty minutes, and reinforced occasionally by traction with his hands. On the last occasion, the head moved an inch and a half along the scapula to the edge of the glenoid cavity and was then thrown into it by a movement of leverage.

"It almost immediately came out again. The next

FIG. 9.—Position of the arm before the operation in one of the cases in which Phelps found a fragment of the glenoid border attached to the capsule. Compare the attitude of the limb with Marston's cases.

day it was reduced and kept in place for an hour. Ten days later it was again reduced and the arm fixed by a bandage. This time reduction persisted. Two years later the limb was found to have gained half an inch in length; the patient could move it inward, outward, for-

ward and backward, could lace her clothes behind her back and play on a guitar.

Manual reduction should be attempted in each case when the patient is under three years of age. Failing in this, operation along the lines laid down by Phelps is clearly indicated. The technique of the method, which he recommended in his paper read in Boston before the American Orthopædic Association in 1898, was "make the incision along the posterior border of the deltoid

cut away and the capsule stitched with catgut." All of this series of cases were dressed with the elbow well back. This is a mistake, for none of the cases has been able to raise the arm quite to the perpendicular. In subsequent cases the arm will be dressed with the elbow well back and with the arm at a right angle with the body, so as to secure this motion, which is the only one that these patients have missed. In his third case, Dr. Phelps encountered sepsis, due to improperly prepared

FIG. 10.—Functional result following Phelps's operation.

muscle, curving it downward. This gives a flap which readily exposes the head of the bone. The capsule is then incised. The head of the bone will be found under the spine of the scapula. It will be necessary to cut away two thirds of the head of the bone, or down to the epiphysial line. The bone should be rounded off, like the original head, and then slipped into the glenoid cavity. The entire new articulation, which has been formed by the head of the bone, is next excised with a chisel or sharp spoon. The redundant capsule is then

suture material. This produced an abscess, which was incised on the anterior aspect of the shoulder. Thorough drainage was maintained, and it is worth relating that this complication did not detract from the almost perfect functional result of the operation.

(To be concluded.)

Honors for the Late Queen Victoria's Physician.—Sir James Reid, Bart., K. C. B., has been appointed a Knight Grand Cross of the Royal Victoria Order.

THE REPRESENTATION OF BILIARY CALCULI
BY THE RÖNTGEN RAYS.*

By CARL BECK, M. D.,

NEW YORK.

I SHOWED the first undisputed skiagraphs of cholelithiasis in living patients, presenting them at the same

well as internists, not only to follow it, but to improve on my technics at the same time. But it seems that the fact that so many before had disputed the possibility of depicting biliary calculi induced others to assume that my skiagraphic interpretations were, to say the least, erroneous.

A few others, less skeptical, who believed in the

time, in this hall, before the New York County Medical Association, on October 16, 1899 (published in the *New York Medical Journal* for January 20, 1900). I then believed that my example would encourage surgeons as

successful representation as well as the correct interpretation, thought that such success was possible under extraordinary circumstances only, and that, as a method, skiagraphy of biliary calculi could not be relied upon. Within a few months my views have been sustained in this country by Nicholas Senn, and by Naunyn

*Demonstrated at the New York Academy of Medicine, January 17, 1901.

n Germany; and Alessandri and Dalla Vedova in Italy have also very recently corroborated them.

The frequent opportunities I have had since to reproduce biliary calculi on the photographic plate have taught me several points which have made me somewhat modify the principles then set forth. The correctness of the obvious maxim, pronounced in my first publication, that, just as in renal or vesical calculi, the skiagraphic result in cholelithiasis greatly depends upon the chemical composition of the calculi, was verified to some extent only. This maxim was based upon my examining the different types of biliary calculi by skiagraphs in order to obtain a visual comparison of their permeability.

But since then I have also succeeded in fixing the common biliary calculi, which I had formerly found permeable to the rays, a light shade only, as a rule, being produced by them. Now, even if they are as small as the head of a pin, they can be distinctly seen. More than this, even calculi of the hepatic ducts are shown. Of course, the mixed bilirubin calculi, which, besides bilirubin-calcium, contain traces of copper and iron, are less permeable to the rays than all the other varieties, and, consequently, a very distinct shade can be expected. The same applies to the pure bilirubin-calcium calculi. Calculi composed of pure cholesterin show as well as, or even a little better than, the common biliary calculi, while the stratified cholesterin calculi, on account of their admixture of calcium, show less permeability to the rays. In consequence, their outlines can be nearly as distinctly shown as those of the bilirubin and the pure bilirubin-calcium calculi. These results, which could formerly hardly be hoped for, I attribute mainly to the excellent qualities of my tubes and their careful selection. They must be carefully studied, individualized, so to speak, as different patients are to be judged differently, although suffering from the same disease.

The condition *sine qua non* for skiagraphic success in such delicate work is a strongly built and powerful tube, which will bear a fifteen-inch spark for about five minutes without becoming too hot.

Another and important requirement of such tubes is that they be of medium hardness, so as to permit of the permeation of the soft tissues without penetrating the dense tissues, like bones or calculi. A tube useful for that purpose can best be tested by the operator's own hand. In fact, the hand is a better indicator than any artificial skiameter, as it contains many types of bones, from the massive carpal end of the radius to the delicate third phalanx of the little finger.

If the bones of the operator's wrist, especially the lower radial epiphysis, appear grayish-black, but still as well-defined structures, while the soft tissues show but lightly, the tube is fit for a fair reproduction of biliary calculi. If a tube shows the bones of the operator light-gray and translucent, the contrast will be insignificant,

and so it will be only fit for the representation of metallic bodies, but not of biliary calculi.

On the other hand, if the tube is too soft, it will show the outlines of the operator's wrist intensely black. This indicates that such a tube will produce excellent skiagraphs of the bones of the hand and forearm; but it will not be powerful enough to permeate the soft tissues of the abdomen with sufficient clearness to show the contrast between them and the biliary calculi.

It is my experience that the tubes which I used for the reproduction of biliary calculi display their energy only so long as they are comparatively new. Later on they show less contrast, just like the very hard tubes, even if provided with an attachment for regeneration. If the tube works well from the beginning, the time of exposure should be about five minutes in thin individuals and about seven in stout ones, provided a Carbutt's or Schleussner's plate is chosen.

The position of the patient while being skiagraphed is also an important factor. He should lie on his abdomen with about three pillows underneath his clavicles, as the elevation produced by them permits of the protrusion of the gall-bladder, thus bringing the calculi nearer to the photographic plate. The approximation is increased by turning the body slightly to the right and raising the left side.

Another point of importance is that the rays should not penetrate the abdomen in a vertical direction, but from the side, so that the thick and less transparent tissue of the liver is not permeated in its whole diameter. The direction of the rays should be such that they form an angle of about 70° with the plate. The tube should be as near the abdomen as possible; the nearer, the more distinct is the picture. As only a small area shows distinctly on the plate, great care must be taken to place the tube in the proper direction. A pencil mark made at the back should correspond to the site of the gall-bladder in front.

The disadvantage of oblique irradiation is that the calculi appear larger than their natural size. When a protrusion palpable in the region of the gall-bladder indicates that it projects from the liver, direct irradiation is to be preferred. In order to exclude any possible source of error from intestinal contents, the bowels must be thoroughly evacuated before irradiation.

By employing this method, not only can the size, shape, and diameter of the gall-stones be determined in suitable cases, but they can also be localized. How important it is to know whether there are also calculi in the liver besides those present in the gall-bladder needs no discussion.

As can be realized by the illustration, which represents the calculi of a man thirty-two years of age, who had fourteen severe colicky attacks during the last sixteen months, even very small sizes can be recognized. In this case the attacks as well as the presence of a painful swelling in the region of the gall-bladder had pointed

to the presence of cholelithiasis before skiagraphy had been resorted to. The presence of numerous calculi in the liver tissue in this case shows that cholelithiasis is often only partially cured by cholecystostomy. They are not so distinct as the calculi in the gall-bladder; still, they are recognizable.

Such facts explain why sometimes calculi have surprised the surgeon, who had evacuated the gall-bladder thoroughly, by their appearance a few days after cholecystostomy. That in cholelithiasis sometimes hundreds of calculi are contained by the hepatic ducts is a well-known experience, but the latter has heretofore been gained only from the autopsy-table.

It is evident that a positive skiagraph renders exploratory laparotomy for suspected cholelithiasis unnecessary. If surgical treatment is declined, it can be ascertained by subsequent exposures whether any calculi have been dislodged or whether some have escaped. If they are of very large size, their removal by any other than a surgical way could, of course, not be expected. So the question of whether or not an operation is advisable in cholelithiasis may be settled by the Röntgen rays. When only small stones are present, there is a chance for medical treatment. When stones are found too large to pass the common duct, medical treatment can only be of a palliative character, and cholecystostomy should be performed as soon as the calculi prove to be a source of irritation.

The old lady whose calculi I had skiagraphed eighteen months ago (see illustrations in my article On the Detection of Calculi in the Liver and Gall-bladder, *New York Medical Journal*, January 20, 1900) was re-examined by me recently. Three skiagraphs, taken at different times and in different positions, showed a negative result. The patient, now more than seventy-three years of age, had submitted to diet and the regular administration of Karlsbad Mühlbrunn for more than a year, and the result was that the tumor in the region of the gall-bladder had disappeared. Her general condition had also improved accordingly, and no colicky attacks were noted during the last eighteen months. So I feel justified in believing that the negative skiagraphs confirmed the impression that the stones had passed away.

I appreciate perfectly that the method I have advised and modified is incomplete and needs further modification and improvement, as there are many delicate technical details upon the correct appreciation of which success depends to a great extent. Skiagraphy of biliary calculi is not so perfect a method as the representation of renal, ureteral, and vesical calculi. While a negative result in the case of suspected renal calculi can now pretty safely be taken as the evidence of the absence of calculi, the same cannot yet be said of biliary calculi with certainty. But, on the other hand, it can safely be asserted that even a faint skiagraphic reproduction of biliary calculi proves their presence to the

expert reader. I am confident that with our increased knowledge and improved technics the skiagraphic reproduction of biliary calculi will soon prove to have become a reliable method.

SUBSTITUTE FEEDING OF INFANTS UPON MILK MODIFIED ACCORDING TO PRESCRIPTION IN LABORATORIES.*

BY W. P. NORTHROP, M. D.,

NEW YORK,

PROFESSOR OF PÆDIATRICS, UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; ATTENDING PHYSICIAN TO THE PRESBYTERIAN, FOUNDLING AND WILLARD PARKER HOSPITALS.

FEEDINGS to fit is the pædiatrist's problem. The growing child has ever-changing needs; it is not the same child more than two weeks. A mother's milk may or may not fit the requirements of her own offspring. A failing milk is usually a poor milk. A wet-nurse's milk may or may not be a fit one. Incidentally, if it is so, her personality may be in the household a hopeless misfit; she may be an impossible thing. For one reason or another, to him who makes the growing child his special charge the same problem forever recurs—feedings to fit.

In substitute feeding we may assume that we all agree that cow's milk is the basis for all beginnings: that the sanitary supervision of the production and the care of milk, its cleanliness and its freshness, and the accurate modification of an infant's milk, are essential. At the outset I may be allowed to say that my paper is to be founded on a rather extensive experience with the system of which our distinguished guest, Dr. Rotch, was the originator and perfecter.

What is required of a modern, well-equipped milk laboratory? Milk of good quality for the feeding of infants and invalids. A good milk is a mixed milk, from herds of native breeds, healthy in the locality in which they live. Such herds should be properly housed, scientifically fed, tuberculin-tested, and constantly under trained, intelligent oversight. The reasonable requirements for the production of good milk must be here fulfilled. In the abstract, to secure the ideal results, the farm, herd, and laboratory should be under the same ownership; the superintendent, the veterinary surgeon, the bacteriologist, and the chemist should be under the supervision of a medical commission of men who are, before all others, interested in the best possible milk product, viz., baby-feeders and fever-feeders. All these conditions are fulfilled in the system which owes its origin to Dr. Rotch.

The modern milk laboratories produce clean milk, milk that has been gathered, stored, and distributed under the best attainable hygienic conditions; milk is not

*Read before the New York Academy of Medicine, October 18, 1900.

clean when it contains dirt, which, from our standpoint as physicians, means living bacteria, whether growing and multiplying at the time or only capable of such growth and multiplication when the conditions shall become favoring; milk is also not clean if the bacterial growth has been arrested after a considerable time—in other words, when the growth and multiplication of the bacteria have developed their product—toxine. It is not improbable that the nursling swallows many bacteria when sucking its food from a perfectly normal breast, but never, under like conditions, does it swallow toxins. In other words, it takes a few bacteria in fresh milk, but what does it escape? It escapes stale milk with multiplied bacteria, and, quite as important, it escapes the toxic products of bacterial growth.

Clean milk, then, means, practically, milk which has been allowed to suffer but the least possible bacterial contamination. Clean milk also means milk in which no bacterial growth has been allowed to go on to the production of toxins. Bacteria infect a baby, toxins poison it. It is impossible to collect milk in large quantities bacteria-free. In many dairies a limit has been set to the unavoidable bacterial contents. Care in milking diminishes bacterial contamination. How can avoidance of toxins be attained? When cooled below 40° F. most bacteria cannot grow in even so good a culture medium as milk. The milk supply of which I speak is cooled to 40° F. within ten minutes of the milking. A car passes constantly back and forth taking milk from the pails to the cooling tank. Note, then—no dirt, no bacteria, no growth of bacteria, no toxins; 40° F. is the bacterial deadline. If one hundred bacteria fall into the milker's pail, they, for the most varieties, must remain one hundred if the thermometer remains below 40° F. Clean milk also means milk that has been protected from the contamination of contagious and infectious diseases in the persons of the milkers and milk-handlers—scarlet fever, diphtheria, typhoid fever, tuberculosis, etc.

Much of the milk delivered in New York is forty-eight hours old. Milk gathered from many separate dairies suffers much more contamination than milk from one dairy, and a long journey in ordinary freight cars, in the case of contaminated milk, is conducive to bacterial growth. The milk supply of which I am speaking is delivered in New York by express, so that the morning's milk is delivered for modification in the afternoon and delivered to patients early the next morning. The aim is to get good milk, clean milk, fresh milk, and, having procured such, to hasten it to New York by express, so that it shall have good care and a short journey and shall remain continuously cool.

Modification of Milk.—The well-equipped modern milk laboratory, furthermore, stands for accurate and clean modification of milk. Granting, then, that we have a milk that is approved—that is, a milk from one herd, milk that is clean, of good quality, fresh—how is

it to be prepared for the baby? Average cow's milk contains, approximately: Fat, four per cent.; sugar, four per cent.; proteids, four per cent. Woman's milk contains: Fat, four per cent.; sugar, seven per cent.; proteids, two per cent. (high average), or, fat, three per cent.; sugar, six per cent.; proteids, one per cent. (low average). How are the proportions to be readjusted? Without entering into the details of modification, it may be said that the cream is first removed from all the milk by centrifugation, the remaining separated (skimmed) milk diluted, and the cream restored to the milk in the required quantity. Discussion will here arise as to the respective values of gravity and centrifugated cream. To me this seems a purely academic discussion; in my experience there has never arisen any accident or incident to raise an objection to centrifugated cream. The all-important freshness of centrifugated cream is an argument difficult to overturn. Centrifugated cream may be taken from the freshest milk; gravity cream requires from six to twelve hours' standing.

Modification of milk consists in the transformation of the proportions of cow's milk to the proportions of woman's milk, and in transforming a slightly acid milk to one of slightly alkaline reaction, in preserving it from bacterial and toxic contamination, in holding it ready in divided quantities for the periodical requirements of the infant; in short, in making a substitute feeding as nearly as possible like a mother's milk.

Advantages and Disadvantages.—The only argument against milk thus modified is its expensiveness. Milk modified in a laboratory must necessarily cost much. Express charges, expert labor, responsible superintendents, chemists, and bacteriologists necessarily increase the price of the product as delivered at the home. I have never allowed this argument to go unexplained. Certainly in no place should economy begin so late as in the nursery.

Having laid so much stress on the proper cleanliness and freshness of the milk, and said that this milk now requires to be modified, the following questions arise: Where can this be done? Can it be done at home by the nurse or by the mother? Must it be done in a laboratory, or can it be better done in a laboratory?

There is a human tendency to change feedings from the order of the doctor. I have on one occasion even known a mother to put chicken broth into the bottles of laboratory modified milk. I would limit the home modification to the cases of children already well started and thriving, to those which are not to be considered as delicate or in a critical state. Really difficult cases, critical cases, in which there is risk in trying different things, in which it is necessary to find the right feeding at once, in which the condition of the child is such that it is important not to risk any time, I have no hesitancy in saying there is no feeding so reliable and so good as the modified milk. The physician cannot take time to teach mothers all that is in his mind in the words clean, fresh,

accurately modified milk, properly divided, sanitarily handled.

When one considers the importance of the result, the time necessary to teach properly the details of the modification of milk for a delicate infant, and the fact that half-knowledge may lead to poor results, it may be said to constitute an objection to the method. Home modification of milk quite as much requires clean, fresh milk, intelligently handled, accurately modified, and in sanitary surroundings. In my experience home modification has been difficult to accomplish, uncertain in results, and often a failure. Carelessness and ignorance of the first principles of bacteriological cleanliness, and more often the over-anxiety to make the infant gain weight, have led to modification of the milk according to the individual wishes of the mother or nurse.

There are also duties on the part of the family physician which must be borne in mind. He must realize that modified milk is not any one thing capable of being ordered, any more than drugs are such. If he sends word to the laboratory to send "feedings proper to a child of such and such an age," he trusts to the clerks of the laboratory to prescribe for the infant which they have not even seen. If the doctor would send word to the drug clerk to provide drugs proper for a case of typhoid fever in the third week, or would tell the friends of the patient recovering from typhoid fever to feed that patient with feedings proper for a person recovering from an exhausting disease—if he would do these things, then I have nothing to say of his prescribing in this scattering way for babies whose requirements change every fortnight and whose growth is of such importance. The doctor should know first what the baby requires in the different periods of its life and development. If he does not know this, I question his ability in these days to do the best for any child. If he is willing to treat the eye or a mastoid abscess himself, without the aid of special knowledge or expert advice from another, then he is willing to feed a growing infant in slipshod ways, and ask the laboratory clerks to prescribe for the babies. Baby-feeding has become a specialty. The time will come when our milk supplies will be much improved. The object lesson set by the work of Dr. Rotch will be followed by marked improvement in all the commercial milk firms about New York. So the time will come when babies will be fed by experts, men whose minds are reflecting on the subject of the feeding of babies. Surgical removal of Meckel's ganglion is a noble work, but it does not prepare one for the proper feeding of the new-born infant. Indeed, it happens that men most skilful in attending the mother in her confinement have very little confidence in their ability to guide the infant through its devious paths in the embarrassments of teething and feeding. It needs to be remembered that cow's milk is, approximately, four per cent. of fat, four per cent. of sugar, and four per cent. of proteids. There are, then, three formulae necessary to remember: 1.

Feedings for the new-born (proper for the majority)—two per cent. of fat, five per cent. of sugar, 0.75 per cent. of proteids. 2. "Low-average breast milk"—three per cent. of fat, six per cent. of sugar, one per cent. of proteids. 3. "High-average breast milk"—four per cent. of fat, seven per cent. of sugar, two per cent. of proteids. These modifications should be changed gradually and frequently by small fractions from one to another. At the age of from eight months to a year, it is time to make the proportions approximate those of whole cow's milk—in other words, wean the child. The feedings should be all milk for the first year, mostly milk for the second year.

In closing, I wish to say that a long and full experience with laboratory-prepared substitute feedings of milk, constrains me to say that I regard the modern well-equipped laboratory as one of the greatest additions that have come to the use of the pædiatrist in the time of my practice of medicine, and that it deserves to rank with diphtheria antitoxine and intubation. For the care of most difficult, critical cases, in which no time must be lost, I prefer to trust to modified milk in preference to the wet-nurse or any of the substitute feedings. I personally feel a deep sense of gratitude to Dr. Rotch for his work in the interests of the profession and humanity. Let us grant to the guest of this evening our full expressions of appreciation; let us say that this is his monument; let him wish no other.

57 EAST SEVENTY-NINTH STREET.

THE SPECIFIC TREATMENT OF ACUTE DYSENTERY.

BY WILLIAM J. CRUIKSHANK, M. D.,

BROOKLYN, N. Y.

(Concluded from page 407.)

We come now to the consideration of that branch of this morbid condition which is the real object of this paper, viz., its treatment. The suggestion that teachers of clinical medicine persist in the advocacy of useless and pernicious drugs in the treatment of this disease may occasion some surprise. Nevertheless, an examination of the subject will show that in the minds of a great number of the most modern writers its treatment is largely empirical. Even Sodré, to whom we are indebted for many original pathological and bacteriological suggestions, fails to acquaint his readers with the best therapeutic results obtained. We are all familiar with the various methods of treatment of acute dysentery which have been suggested by the different textbooks. The variety of drugs which have been used in the effort to find some remedial agent which will give uniform results is very great; and this fact will become doubly interesting if we find the solution of the problem to be in the use of a simple purgative. Certain it is

that we find many eminent, and even some of the most recent, authorities, opposing this view. For example, no less an authority than Osler takes the position that purgatives are objectionable, and further expresses the opinion that the profession has largely given up their use. It is true that he, like others, suggests a saline purgative early in the disease, and says that it may be repeated if scybala are present, but beyond this he does not go. Conclusions similar to Osler's, regarding the use of so-called purgation in this disease, are traditionally orthodox, the majority of writers subscribing to them. Nevertheless, these conclusions have no real foundation in fact, and are absolutely controverted by recent and careful clinical observation. By a well-defined use of a certain medicine which is commonly called a purgative, we obtain in this disease a depletion of the inflamed tissue which, when compared with purgation *per se*, differs very materially; and I am convinced that a lack of appreciation of this suggestion has resulted in the sacrifice of human life which otherwise might have been saved. I cannot describe the chaotic condition of the text-books on this subject better than to quote the words of Dr. Westlake, who officially observed an epidemic of acute dysentery in California, and who reports his experience in the *Occidental Medical Times* of 1889. "How we revelled in materia medica!" he says. "What volumes of therapeutics we ransacked; what vast storehouses of concentrated and diffused wisdom we read in the immortal works of Flint, Watson, Aitken, Bartholow, von Ziemssen, Tanner, and Niemeyer; and what a humiliating corollary from this vast storehouse of epidemic dysentery literature, when we had to fall back on plain, old-fashioned Epsom salts!" Even in this instance Dr. Westlake was governed almost entirely by the older writers in the treatment of his cases, using his sulphate of magnesium for the purpose only of removing faecal matter from the intestines. If the early morbid changes and the bacteriology of a disease *ever* suggested a rational plan of treatment, it is certainly suggested here; and I have been led to form the opinion, based necessarily, however, on the personal observation of a limited number of cases, that we have in the sulphate of magnesium, when properly administered in acute dysentery, a remedy which approaches as nearly to a specific as does quinine in the treatment of true malarial infection, or mercury and iodide of potassium in syphilis; and I think I may safely add that I am borne out in this opinion by the most recent clinical observers. It is agreed that we have in this difficulty to deal with various grades of inflammation involving the mucous and submucous membranes of the large intestine, caused by the introduction into the intestinal tissues of a micro-organism. There is no disputing the fact that this inflammation differs not materially from other inflammatory and necrotic processes of like character, except that it has for its origin the *Amœba dysenteriae*, or admittedly, for the sake of argument, some

other germ. The inflammatory process begins with the customary and consequent arrest of normal secretion, and is followed by the usual pathological changes, viz., hyperæmia, œdema, softening, infiltration, necrotic changes, rupture of blood-vessels, abnormal secretion, and, finally, complete ulceration. To this mischievous condition we have added the specific infection, together with other pathogenic micro-organisms. Now, if we would effectually remedy this morbid process, we must first eliminate the cause, disinfect the mucous and submucous tissues, and restore the normal glandular secretion; hence the great necessity of attacking the disease early in its inception. The sulphate of magnesium, if properly administered, will, I think, accomplish this result. In all cases of acute dysentery, from the beginning of the attack until there is a subsidence of all the symptoms, it should be administered in drachm doses every three hours, dissolved in one or two ounces of distilled water, to which may be added ten drops of the dilute sulphuric, or aromatic sulphuric, acid. Experience has proved conclusively the unprecedented results which may be obtained from the use of this drug in the manner described. The beneficial effects are shown in a very few hours after the commencement of its use, and in from twenty-four to forty-eight hours the patient's condition shows marked general improvement; the pain becomes less, the tormina and tenesmus rapidly subside, and there are diminution of the pulse rate and lowering of temperature. If tympanites is present, it is rapidly reduced; the stools become less painful and less frequent, the blood and mucus disappearing. At the end of forty-eight hours, in the vast majority of cases, the stools take on a biliary character. The treatment must now be continued steadily until the stools become nearly normal. When this result is obtained, the medicine may be gradually withdrawn; the average time required for the establishment of convalescence being from three to six days from the commencement of the attack. The disease occurring in children should also be treated in this manner, the dose of the sulphate of magnesium and sulphuric acid being governed by the age of the child. Not the least interesting point in this plan of treatment is its *modus operandi*, and this branch of the subject involves many interesting suggestions.

The hypothesis which seems to me to be the most reasonable is the following: By stimulating the naturally sluggish hepatic organ to greater activity, the sulphate of magnesium increases biliary secretion, and in this way acts somewhat antiseptically. In making the statement that the bile acts in any sense as an antiseptic, I fully realize the fact that I am dealing with a mooted question, as has been thoroughly proved to me by recent investigation of the opinions expressed on this subject by physiologists. Nevertheless, careful physiological experimentation leaves the question still unsettled, diametrically opposite views being expressed by equally

eminent writers, some of them holding that the bile is utterly lacking in antiputrefactive qualities, while others claim that it diminishes putrefaction in the large intestine. Notwithstanding this conflict of opinion, I feel constrained to the belief that the bile, either directly or indirectly, exerts some antiputrefactive action in this disease. To be sure, my observations are essentially clinical and necessarily of a practical character. The manner in which the sulphate of magnesium produces other beneficial results obtained from its use in this disease, seems to me to be reasonably simple. Undoubtedly it abstracts water from the surrounding tissues, and by endosmosis pours it through the mucous and submucous tissues into the cavity of the intestines, eliminating the infection from the submucosa, depleting the mucous membrane, and thereby reducing the inflammatory process, washing out the contents of the intestine and thus ridding the canal of the infectious material. As a depletent, under circumstances where it is indicated, the sulphate of magnesium has, in my opinion, no equal. By its antiphlogistic action, in acute dysentery, it lessens the tormina and tenesmus, reduces the bodily temperature, relieves the pain, depletes the blood-vessels, and in this way removes the congestion and restores the normal secretion. The physiological action of this drug has for years been thoroughly recognized by the gynæcologist, and also by the general surgeon, who use it to great advantage as a depletent in acute and chronic morbid conditions involving the pelvic organs and abdominal viscera. Many therapeutists and teachers of medicine, who have extolled its depleting qualities in other similar pathological conditions, have neglected, strangely enough, to apply the principle to the treatment of this disease. They have insisted, and continue to insist, upon administering astringents and other medicines, which can have no other effect than to lock up the secretions, when, as a matter of fact, the only rational indication, it seems to me, is to increase elimination, and, in a proper manner, restore the already diminished glandular functions. Even so recent and so eminent an authority as Loomis went so far as to recommend in this disease the use of opium to the point of narcosis. This suggestion seems to me to be in direct opposition to all the indications for the rational treatment of any such pathological condition, and must be productive of much harm when applied to the disease under consideration. To treat acute dysentery by the administration of opium to the point of narcosis is suggestive of the action of the ostrich, which buries its head in the sand in the firm belief that because it cannot see its enemies it cannot be seen by them. Is it possible that by narcotizing the patient with opium, and thereby locking up his eliminative forces, we are ridding him of his dysentery? Are we not in this way doing just the reverse? Does not every dose of opium which we administer in acute dysentery tend to deceive us by masking the enemy and paralyzing Nature's method of rid-

ding herself of him? Does not the dysentery still exist even though the patient is narcotized? Do we accomplish anything more by the use of opium in this disease than the temporary relief of pain by which we are ourselves lulled into a feeling of false security? Is not the explanation of the almost universal use of opium in acute dysentery to be found in traditional errors in the ætiological conception of the disease, together with blind and empirical attempts to control its symptoms?

Previously to the excellent paper on this subject which was contributed by the late Dr. W. H. Thayer and read before the Medical Society of the County of Kings, my own experience had led me to the conclusion that the rational treatment of acute dysentery should be along the lines herein suggested. I was led to this belief from the following single experience: A number of years ago, I was called upon to attend a young lady who was suffering from a severe attack of acute dysentery. All the symptoms of the disease were well marked, including tenesmus and tormina, frequent and bloody stools. I treated her after the orthodox fashion, alternating the administration of sulphate of magnesium with opium. I observed that when the sulphate of magnesium was given to her, all the symptoms were relieved and her general condition had rapidly improved. But, fearful to diverge too much from the plan of treatment which was then in vogue, and which was laid down in the text-books, I did not have the courage to persist, and after moving the bowels thoroughly with the sulphate of magnesium, I had recourse to opium combined with bismuth. The administration of these drugs was invariably followed by a return of all the dysenteric symptoms, including increased frequency of the bloody stools. Eminent counsel who saw the patient with me advised a continuance of the plan of treatment which I had inaugurated, with the result that the disease terminated fatally on the fourteenth day of the patient's illness.

My experience with this case taught me a lesson which I have never forgotten; and I then concluded that many of the suggestions for the treatment of acute dysentery which were to be found in the text-books were useless, if not absolutely harmful. Since then I have treated all the cases of acute dysentery which have come under my observation in the manner above described, with uniformly good results. About ten years ago I was called to see a gentleman who had recently arrived from Havana, and who was suffering from suppurative hepatitis which followed an attack of acute dysentery contracted in Cuba. The inflammatory process extended from the hepatic organ through the diaphragm, perforating a bronchus and resulting in a fatal septic pneumonia. The patient was seen at my request by Professor McCorkle, who corroborated my diagnosis. An autopsy revealed the conditions which have been described. Shortly after the man's death, his mother and grandmother, who had nursed him during his ill-

ness, were suddenly seized with acute dysentery; his mother was sixty years of age, and his grandmother was eighty-three years of age. The cases were both severe, the grandmother having from thirty to forty stools containing blood and mucus during the first twenty-four hours of the disease. In fact, she passed blood and slime almost constantly; tenesmus and tormina were also prominent symptoms. Both these patients recovered under the administration of sulphate of magnesium in the manner described, after an illness of five and seven days, respectively. These two cases are also interesting, owing to the bearing they both have on the question of contagion. Other similar cases occurring in my own experience might be cited, but I prefer, and ask permission, to refer you to the clinical reports of more competent observers. Dr. F. Wyatt Smith, in the *British Medical Journal* for January 29, 1898, published his experience in the treatment of acute dysentery. He says: "In the British hospital at Buenos Aires and Montevideo, I had charge of a number of cases of acute tropical dysentery in the persons of sailors from ships in these ports, and from Rosario, Santos, and Rio Janeiro. I treated the first few cases with powdered ipecacuanha, in classical fashion, but, in spite of all precautions in administration, I could get nothing greater than a homœopathic, useless, dose retained, and in most cases the first dose was the last the patients would submit to taking at all, so nauseous did they find it. The type of disease, as I saw it, was doubtless severe, for all my patients died long before the arrival of the eighth day brought any hope of natural recovery." The author further says that, on the advice of some local medical friends, he tried the administration of opium; the result was, if possible, even worse than under the ipecacuanha treatment. "In despair," says Dr. Smith, "I turned to the administration of sulphate of magnesium at frequent intervals, and it acted like magic. In fact, thereafter I lost only one case; and that is the most instructive of all. It occurred in the person of an able-bodied seaman from one of Her Majesty's ships, who was brought in collapsed, delirious, and passing blood and slime in large quantities almost constantly; he was being treated with opium; and grew rapidly worse; in fact, he was sent ashore to die. Magnesium sulphate in large and frequent doses was substituted for the opium, and the patient began to improve rapidly, when, twenty-four hours later, he was seen by a consultant, who insisted upon a return to the opium, in spite of the fact that the discharges were made less frequent and contained less blood and the patient rational and able to sleep quietly." Dr. Smith's urgent and earnest entreaty that the plan of treatment which he had adopted should be carried out, was disregarded, and he was compelled to administer opium in half-grain doses every three hours. Blood almost immediately reappeared in the stools, and, shortly after the beginning of the administration of the opium, the man died. Dr. Smith concludes his account in these words: "But this

case confirms the conclusion to which the uniform experience of a large number of cases of acute tropical dysentery had brought me, namely, that *ipecac is useless, if not worse; that opium is positively pernicious in these cases; that the treatment of dysentery is essentially purgative, and that magnesium sulphate is practically a specific.*" Surgeon-Captain Johnson, of Her Majesty's service, in following up the suggestions made by Dr. Wyatt Smith, published his conclusions as the result of *six years of treatment of acute dysentery with magnesium sulphate.* These conclusions were published in the *British Medical Journal* of April 16, 1898. He says: "I came to the same conclusion as described by Wyatt Smith, that the treatment of tropical dysentery, or acute dysentery of any kind, with ipecac, is not what it is reputed to be, so I treated it with Glauber's salt in small doses. This I shortly rejected, as the results were not encouraging, and in 1891 I began treatment with magnesium sulphate in small doses, since which time I have had excellent results." "Magnesium sulphate in this form," continues Johnson, "appears to me, from its physical action, to be the drug *par excellence* for counteracting the pathology of dysentery." Dr. Johnson further says that from his experience in India he has been led to the conclusion that ipecac has not the effect with which it was formerly credited, and he strongly recommends the use of magnesium sulphate. *He says that patients may come into the hospital passing fifteen stools per diem, containing blood and slime, and that when treated in the following manner the average duration of the attack is only two or three days, even for those on field service.* "The patient is at once put on a purely milk diet, and is given two drachms of magnesium sulphate every four hours, combined with aromatic sulphuric acid, five minims, to counteract any severe griping that may be caused, till the flow of bile is well established, as seen in the stools."

Dr. J. L. Dickey, medical officer of one of the Bengal railways, in the *British Medical Journal* of June 9, 1900, speaks in the highest praise of the sulphate of magnesium in this connection, saying: "I find the treatment of the greatest value in cases of acute dysentery, both in natives of India and in Europe." Dr. Dickey recorded a large number of cases which he treated by giving one drachm of a saturated solution of magnesium sulphate, to which was added ten drops of dilute sulphuric acid every two hours until the motions became copious, fœulent, and free from blood and mucus. "Unfortunately," says Dr. Dickey, "all complete records of these cases were destroyed in the earthquake of 1897."

But the most interesting of all reports is that of Surgeon-Major W. J. Buchanan, which is to be found in the *British Medical Journal* of February 10, 1900. Dr. Buchanan reports *102 consecutive cases* which were treated with small and frequent doses of saturated solution of sulphate of magnesium, *with one death*, and four hundred and fifty-three cases treated with the sul-

phate of sodium in about the same manner. All of these cases occurred in the Central Prison of Bhagalpur, Bengal, and Dr. Buchanan says, "the cases were all types and forms just as they occurred from day to day." *In all, there were 555 cases, with six deaths.* The first 102 cases were treated with sulphate of magnesium, the sulphate of sodium being substituted for the magnesium salt in the treatment of the remaining 453 cases, owing to the fact that Dr. Buchanan ran short of the former. In the vast majority of cases, the treatment was continued for from eight to twelve days. It would be interesting in this connection if we had some definite information concerning the medical treatment which our soldiers and sailors, who suffered from this disease, received during the Spanish-American war. No such knowledge is at my command, except some incidental remarks of Flexner, which are to be found included in the reports of his autopsies. These remarks, however, would lead us to the conclusion that such drugs as ipecac, bismuth, and quinine were used to a very considerable extent, the use of no other drugs being mentioned.

Before leaving the consideration of the subject of the treatment of this disease, I desire to add a word regarding the question of protective inoculation and serum therapy, as it has been applied by Shiga, an account of which is to be found in Professor Flexner's article, to which I have before referred. "Larger animals, such as the goat," says Flexner, "when treated first with the dead and afterward with the living cultures, develop a gradually increasing resistance to the inoculations; their blood serum assumes highly agglutinating qualities for the bacillus, and, coincidentally, acquires protective and healing qualities. Shiga has tested this serum upon human cases, and Dr. Eldridge reports the results up to November 1, 1899. In 1898, sixty-five cases were treated, with a death rate of nine per cent. In 1899, ninety-one laboratory cases were treated, with a death rate of eight per cent., and 110 hospital cases were treated, with a death rate of twelve per cent. During the same period of 1899 there were under ordinary treatment at Tokio, at Hirowa hospital, 116 cases, with a death rate of 37.9 per cent.; and in private houses, 1,119 cases, with a death rate of 28.5 per cent."

These results speak for themselves, as do also the results obtained in Bengal by Buchanan, with the use of sulphate of magnesium, *the death rate in his cases being one and eight tenths per cent.*

Are we, then, justified in waiting for the bacteriological confirmation of the ætiology of this disease before adopting a plan of treatment which is actually thrust upon us by every investigation of its pathology—a plan of treatment which is not only rational in theory, but which has really demonstrated its ability to reduce the death rate of acute tropical dysentery from twenty-five per cent. to a practical one per cent.? Has the clinician gained anything for the actual treatment of malarial infection, resulting from the discovery of the

plasmodium? Have we not for years successfully treated syphilis without definite knowledge as to its specific ætiological factor? Would the discovery of its specific micro-organism aid us materially in the treatment of its morbid phenomena, and should we, as rational therapeutists, reject the best means at our command for controlling its mortality, simply because we must confess ignorance regarding its specific ætiology? In the light of our present knowledge, is the clinician, into whose hands the victim of acute dysentery necessarily falls, further justified in the sacrifice of human life on the altar of traditional empiricism while the bacteriologist continues his technical search for the establishment of specific theories regarding the ætiology of the disease?

Finally, I beg to submit for your consideration the following conclusions:

1. That dysentery is a disease of great gravity.
2. That it is both contagious and infectious.
3. That it is caused by the introduction into the system through food and drink, also through the air, of a specific micro-organism, the identity of which seems to be still in doubt.
4. That dysentery is one disease, in whatever latitude it may be found, and the only varieties which have any foundation in fact are those which may be based on the intensity of the morbid process.
5. That the majority of the therapeutic agents which have been suggested for the treatment of acute dysentery are useless, and in many cases harmful.
6. That sulphate of magnesium, properly administered, in the acute form of this disease, acts as a specific.

102 FORT GREENE PLACE.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

By NEIL MACPHATTER, M. D., C. M., F. R. C. S.

NEW YORK,

ATTENDING SURGEON, POST-GRADUATE HOSPITAL.

(Continued from page 410.)

DISEASES OF THE FETAL APPENDAGES.—The local pathological conditions that may interfere with the nutrition of the foetus and cause its death and expulsion are exceedingly important to the physician. It is only by having a clear and distinct understanding of this subject that we can intelligently meet the emergencies which may arise. For this reason I now proceed to enumerate the various causes of intra-uterine death which may be directly attributable to pathological conditions of the foetal envelopes and foetal appendages. Because the decidua is the earliest in point of formation, its numerous faulty conditions will be considered first. It consists of the mucous membrane lining the uterus, thickened and developed so as to fulfil the necessary requirements of a uterine envelope. At each menstrual period this mucous membrane becomes

swollen and of a velvety appearance, and then separates from the underlying structure, and may be considered an immature decidua. It becomes disintegrated and is thrown off in the menstrual discharge. On microscopical examination, this discharge is found to be composed of the superficial lining of the uterus, as well as of the deep, spongy layer adjacent to the muscular wall of the uterus. There is but a difference of degree only between the menstrual decidua and the decidua of pregnancy. When a vitalized ovum appears in the cavity of the womb while the decidua of menstruation is forming, the formative elements will take on greater activity, and it will develop into a foetal envelope to which the ovum may become attached. The mucous membrane then grows around the ovum so as to envelop it in a distinct sac. That part which is reflected around it is known as the *decidua reflexa*. That which remains covering the uterine cavity is called the *decidua vera*, and that part to which the ovum is attached becomes the *decidua serotina*. From this serotina the uterine part of the placenta is afterward formed. Normally, the mucous membrane of the uterus is covered by ciliated epithelium, but toward the end of the first month of pregnancy this epithelium disappears, and shortly afterward the uterine glands are lost. About the middle of pregnancy the space between the decidua vera and the decidua reflexa is obliterated and the two membranes become welded together. Sometimes a well-formed membrane, and one which in minute structure and appearance bears a striking resemblance to the decidua of pregnancy, is expelled from the unimpregnated uterus during a catamenial period. It usually gives rise to a great deal of pain and is known as membranous dysmenorrhœa. It is probably due to reflex irritation in some part of the uterine machinery, deluding the latent cells and fibres of the mucous membrane into great activity, under the belief that a fertilized ovum is in the uterus. It must not be understood, therefore, when such a membrane is expelled, that an abortion has taken place. When, however, in married women, such membranes are persistently thrown off, they are probably the result of pregnancy. This conclusion is arrived at, not from any distinct evidence of finding an ovum in the meshes of the discharge, but from the fact that, usually, when sexual relations are held in abeyance, the expulsion of such membranes ceases until the renewal of these relations. An additional piece of evidence in favor of the belief that they are due to conception in such cases is the fact that the catamenial period is generally missed for some time before their expulsion. Sometimes these membranes come away entire and are then of triangular form and represent the shape of the uterine cavity. An antecedent endometritis is generally traced in these cases. When the impregnated ovule engrafts itself upon this inflamed mucous membrane the attachment is not sufficiently strong for the decidua to properly maintain itself. When such a membrane is examined the cavity

is usually found empty. The ovum cannot be found. It has either missed getting into the uterine cavity, or, as is more probable, has not had sufficient inherent vitality to attach itself into the decidual tissue. In such instances the fault is likely to lie in some defect in the spermatozooids. The fecundating fluid may be deficient from any of the various reasons already given. These membranes are not always thrown off in one piece. Generally they are seen in shreds or detached pieces. Part of the membrane may be retained and be cast off at a subsequent date. These decidua may sometimes be found covered with blood, and, in the cavity, an organized clot can frequently be seen. In the very early periods of pregnancy it is almost impossible to distinguish the presence of any of the elements of conception without the aid of the microscope. A peculiar condition of the decidua, and one somewhat similar to this, was first recognized and described by the late Matthews Duncan. It is a deficiency of development in that part of the decidua that normally grows around the ovum. Instead of the ovum attaching itself firmly against the uterine decidua, only a limited part comes in contact with this surface. The consequence is a more or less pedunculated attachment. Sooner or later, the ovum in such instances perishes and is cast off. From its frail adhesion, any unusual exertion or fall may be sufficient to cause its expulsion. When it is not thrown off in this manner, the embryo will eventually suffer for the want of nourishment and gradually wither away. This is probably only one of many defects of development of the decidua in the early stages of gestation. Rarely the ovum fails to get inside the decidual cavity. It then lies between the outer wall of the decidua and the uterine wall. It forms an attachment to the surrounding structures very similar to the manner in which an ovum forms its adhesion in tubal pregnancy. Such attachments, however, are deficient and lacking in the necessary elements for the proper nourishment and development of the ovum, which forms a sort of pretense at growth, but eventually all such perish. All varieties and degrees of insertion of the ovum into the decidua have been described by various authors. A very frequent cause of death of the foetus is an arrest of development of the decidua reflexa. The ovum, in such a case, is not sufficiently sustained, and generally sags down and becomes pedunculated. The only covering it has is that furnished by the chorion. Such attachments are extremely slender, and any unusual exertion or violent exercise may be sufficient to cause its detachment and expulsion. It is very seldom that pregnancy progresses for any length of time under such circumstances. Besides the several anomalies of insertion of the ovum, and the great liability to abortion following, there are frequent occasions when the decidua may be greatly hypertrophied, so as to produce many alterations of the chorionic villi with which it is in contact. Again, the decidua may be too thin and scanty, and the serotina

so defective in development that the placenta which it forms will be altogether too small for the needs of the embryo. After the fertilized ovum has become successfully implanted into the swollen and velvety surface of the decidua and normal development has begun, there are many opportunities for deviations and a great tendency for some women to miscarry. The decidua is abundantly supplied with blood-vessels that are constantly undergoing changes and modifications of size and distribution, in order to meet the requirements of the growing ovum. Because of this excessive vascularity of this membrane, and for the further reason that it is composed of unstable, lax tissue, extravasations of blood between the membrane itself and the uterine wall are extremely prone to occur, especially in frail, delicate women. In some women any sudden shaking, stumble, or fall may be sufficient to cause a part of the decidua to separate from the wall of the uterus and a certain amount of hæmorrhage to occur. According to the extent of the detachment will be the degree of extravasation. Small, circumscribed patches frequently separate the decidua from the walls of the uterus, and are followed by slight hæmorrhages without producing any serious consequences. The rupture of a blood-vessel occasionally takes place in the meshes of the decidua, or there may be a rupture separating the decidua from the uterus and then perforating into the substance of the decidua as well. It can readily be understood that according to the location and extent of these extravasations will be the degree of danger to the embryo. When they take place toward the fundus, and when they are circumscribed in extent, they need not interrupt the progress of pregnancy. When, however, they are more extensive, and separate a large portion of the decidua, they interfere with the nutrition of the embryo and eventually cause its death and expulsion. Many of the vague cases of hæmorrhage that are seen during the progress of pregnancy, and are exceedingly puzzling to the physician, are cases of this character. When the separation takes place high up in the uterus there will be no external manifestation of hæmorrhage, but only vague and uncertain symptoms which cannot be well defined. Occasionally the hæmorrhage burrows downward to the cervix by separating the decidua from the uterine wall, and may be followed by an extensive hæmorrhage. These cases are nearly always followed by abortion. It is not an unusual occurrence in the early stages of gestation for hæmorrhage to take place into the decidual cavity and to fill it with coagula. This presses so upon the embryo as to destroy its vitality. The clots may be so extensive as to entirely obliterate all semblance of an ovum. Generally they can be found wrapped up in the budding folds of the chorion floating about in the fluid part of the blood in the decidual cavity. Along toward the third month of gestation the decidua reflexa is fully developed, and the chorionic villi have by this time embedded themselves in its substance.

By this time, too, the young placenta is beginning to form and to send out delicate anastomotic loops toward the villi of the chorion. While these tender structures are undergoing these incessant changes, hæmorrhages are most liable to take place, but they are of a different character to the hæmorrhage that takes place between the decidua and the uterine wall. It will be remembered that, during the progress of development, the villi of the chorion gradually approach the decidua, and when they have reached its surface they insinuate and push the villi into its substance. Small anastomotic loops from the decidua surround these villus-like webs. These small blood-vessels eventually form part of the placenta. From this period the decidua becomes a highly vascular structure, particularly at that part that becomes the future placenta; the blood-vessels which appear in its substance as small capillaries increase in size rapidly and, as necessity requires, eventually form sinuses, which are constantly filled with maternal blood and into which the fœtal villi are suspended; here it is that the future embryo receives all its nourishment. It should surprise no one, therefore, to learn that during this wonderful and unique adjustment of such frail and delicate structures hæmorrhage should take place from the breaking down of some of these loops. Hæmorrhage occurring here is more dangerous to the embryo than is that which takes place between the decidua and the uterine wall. In this, the blood may become extravasated between the decidua reflexa and decidua vera, and may be so extensive as to fill up the whole cavity, or it may occur between the decidua reflexa and serotina and the chorion, and may be so extensive as to quickly cause the death of the embryo from compression. All gradations of hæmorrhages may take place in these delicate structures. They may be so slight as to give rise to no symptoms whatever, and to do no injury to the embryo; or they may be so extensive as to interrupt the normal circulation and nutrition of the fœtus. There may not be sufficient interference to cause the death of the fœtus, but yet enough to gradually impair its normal development. Its growth is, as a consequence, more or less stunted, and, should it survive to the period of normal birth, it will probably be so frail and shriveled as to be unable to prolong life. It may be that, when such interference with the proper nutrition of the fœtus takes place, it may not be general. Part of the embryo may be properly nourished while the other part is not, and as a consequence there may follow a disproportion in different parts of the fœtus. It is quite probable that certain congenital defects and malformations may thus be accounted for.

Hæmorrhages between the chorion and the decidua form one of the most frequent local causes of death of the embryo during the early stages of gestation. This condition constitutes the apoplexy of the ovum so frequently mentioned and described by various authors. It is found in all degrees of form, and a variety of causes

has been given for its occurrence. There is no doubt that defects of early development may produce it, as well as unusual exertions, as falls and stumbles. These are without question the direct causes of many of these hæmorrhages, but they are only contributory. The far-back commencement and the indirect influences leading up to these hæmorrhages are to be found in many instances in certain general constitutional defects. One of the prominent morbid conditions of the decidua is that of intense engorgement. On minute investigation of the blood-vessels of the decidual membrane, it is found that they are much larger in calibre, and somewhat more tortuous, than in normal conditions. This state of congestion can be followed into the sinuses and farther back into the substance of the uterus. All diseases accompanied by passive congestion have a tendency in this direction. Under this head may be mentioned valvular disease of the heart, chronic Bright's disease, cirrhosis of the liver, and certain disorders of the portal circulation. Plethoric women frequently are prone to apoplexy of the ovum. This bears out the theory advanced in a previous paragraph on this subject, where we maintained that the reason that very obese women were difficult to impregnate, and when they did become impregnated that pregnancy seldom advanced to the full term of gestation, was that in such conditions the endometrium was in a constant state of congestion, and it was with difficulty that an ovum could become attached to the engorged uterine wall. Much will depend upon the amount and degree of the engorgement. Hyperæmia and congestion are sufficiently adequate to bring on a rupture of these frail blood-vessels and cause such extravasations between the membranes. Frequently without extravasation the death and the expulsion of the ovum can be brought about simply by the irritation that may be induced. In certain women there is such a disposition to miscarriage that almost any indiscretion will precipitate abortion. In many instances no such constitutional reasons can be found for these early hæmorrhages. It is then obvious that the separation of such ova is clearly traceable to violence. The structures show no evidence of morbid transformation, and the extruded embryo indicates that they have torn away from the uterine wall in shreds, due no doubt to some traumatic cause. There can be little doubt that embryonic death in the early stages of pregnancy is much more common than is generally believed. There is no accurate means at our disposal of learning the comparative frequency of such conditions, because in the first few weeks they are frequently extruded unobserved.

These extruded ova, on minute examination, frequently show evidences of fatty degeneration. Distinct oil-particles, granule-cells, and broken-down connective tissue can be found in the parenchyma of the decidua and penetrating into the interior of their cells. The blood-vessels, which are so numerous throughout this

membrane, and which form anastomotic loops on the surface of the villi, undergo a similar change. A study of this degenerative process as affecting the decidua is singularly interesting. In my earlier investigations on the subject the conclusion that had forced itself upon my labors was, that this condition was to be accounted for by after-changes taking place in consequence of extravasations of blood produced by general or local causes. Upon further and more careful investigation, it was found that, in quite a number of instances, this fatty degeneration was present in placenta when there had been no blood-clots, and in others the clots were so far distant from the degenerative process as to exclude it entirely as a predisposing cause. In normal conditions the parietal decidua does not participate in the formation of the placenta, but just so soon as its function ceases on the formation of the placenta, there takes place a gradual destruction of some of the protoplasm and a veritable fatty degeneration sets in. This degeneration should not, however, extend farther than the limits of the placenta, but the two are so intimately associated that it would not require much perversion of this process to extend beyond the limits and then to invade the placental decidua and impair its function. Ercolandi, whose researches into this subject are well recognized, concluded that hæmorrhages and the formation of blood-clots of various sizes between the decidua and the chorion were brought about by a fatty degeneration of the decidua serotina at a time when the young placenta should be forming. This breaking down of the tissues immediately surrounding the blood-vessels of the parts necessarily removes a certain amount of pressure and support, and favors rupture. When such hæmorrhage takes place in the tissue of the serotina, its anatomical structure will permit it to burrow from one cotyledon to another until the sinuses are more or less choked with maternal blood. This may take place suddenly or slowly, according to the extent of the degenerative process and the proximity of this process to the vessel walls. As a consequence, there will be almost complete cessation of nutriment to the young embryo, and it inevitably perishes and is cast off. Some authorities maintain that the rupture of blood-vessels of the decidua, where its structures take part in the formation of the lacunæ, accounts for many of these hæmorrhages.

(To be continued.)

A Higher Death Rate in Boston.—The statistics of the Boston board of health for 1900, which have just been made public, show the death rate last year to have been 20.82 per 1,000 inhabitants, as against 20.12 in 1899 and 20.09 in 1898. The latter figure is the lowest death rate recorded since 1865, the highest being 30.43 per 1,000, in 1872. Consumption, as heretofore, leads as the cause of death, 1,247 deaths having been ascribed to this disease.

ANGEIOMA CYSTICUM OF THE NOSE.*

By HENRY LEWIS WAGNER, M. D., Ph. D.,

SAN FRANCISCO,

PROFESSOR OF RHINOLARYNGOLOGY, SAN FRANCISCO POLICLINIC,
UNIVERSITY OF CALIFORNIA; FELLOW OF THE AMERICAN
LARYNGOLOGICAL ASSOCIATION; MEMBRE CORRESPONDANT
DE LA SOCIÉTÉ FRANÇAISE D'OTOLOGIE, DE LARYNGOLOGIE
ET DE RHINOLOGIE; PRESIDENT OF THE SAN FRANCISCO
GERMAN MEDICAL SOCIETY; PRESIDENT OF THE SOCIETY
OF THE EYE, EAR, NOSE, AND THROAT SURGEONS
OF SAN FRANCISCO.

In rhinopathology we have not yet a distinct classification of the different varieties of cysts. It has been

the angioma cysticum, of which I have observed but two cases in the last fourteen years.

This form of cyst differs from others not only from a histological (regarding its structure), but also from a chemical point of view (referring to its contents); it is rare and has been observed, according to their description, only by a few others (Potter, Lublinski, *et al.*), who named it cystoma, or retention cyst.

My own cases were observed and studied in a boy nine years old and in a woman twenty-eight years old. Both presented practically the same conditions, and I

The larger of the black round dots represent erythrocytes. The smaller ones are nuclei of the connective tissue. The erythrocytes are slightly exaggerated as regards their diameter, in order that a distinction may be made between them and the nuclei. The black solid spaces are blood-clots. The fine dots in the squamous epithelium represent shading of the tissue: the larger ones represent the nuclei. *a*, interior of the cyst; *b*, cavernous sinus; *c*, beginning of squamous epithelium; *d*, ciliated columnar epithelium; *e*, connective tissue; *f*, fibrous tissue; *g*, vein.

my aim for some time past to study these new growths. To-day I shall describe to you only one class of cysts,

* Read before the American Laryngological Association at its Twenty-second Annual Congress.

shall give you, therefore, only a brief *résumé* of the analytical results obtained.

Macroscopical.—The nasal passages present no other pathological condition than a single bluish-gray tumor

obstructing the entire posterior portion of one side of the nose and protruding somewhat into the nasopharyngeal vault. The touch with a probe—one of the most valuable instruments for rhinodiagnostic purposes—is very characteristic; this tumor shows a greater elasticity of its outer walls than any other found within these limits, such as an ordinary myxoma or myxofibroma. It is very movable and attached to a small base apparently a little distance below the foramen sphenopalatinum, where the sphenopalatine artery and vein enter the nasal cavity.

During and after extirpation of the tumor a light brownish fluid escaped, leaving a very thin collapsed sac of a sausage form; the fluid was collected for chemical analysis. If the seat of the cyst is not thoroughly destroyed, as by the galvanocautery, it will very rapidly form again. Owing to this, I had the good opportunity in one case of gathering a sufficient amount of this cyst fluid for chemical research.

Microscopical.—In the sections of the cyst walls diametrically cut (see drawing) we observe a ciliated columnar epithelium covering nearly the whole external part of the growth, with the exception of a certain portion, which consists of squamous epithelium (produced either by pressure or by continuation of the mother-stratum). No glands are to be found in any of the sections, but a large number of venous blood-vessels, some of them enlarged, running parallel with the sac; also some large venous sinuses are seen. As the venous blood-vessels and cavernous sinuses constitute the principal elements of this cyst wall, I have therefore termed this growth *angioma cysticum*.

Chemical Analysis of the Cyst Fluid.—The specific gravity is somewhat lower than that of blood serum and has an alkaline reaction; the brown color is partly due to lutein (lipochrom) and partly to a derivative of hæmoglobin. Serum albumin was found in larger quantities in comparison with metaglobulin and paraglobulin, which were present only in small quantities. Neither mucin, paramucin, albumoses, peptones, leucocytes, nor cholesterin crystals were found; only a few red blood-corpuses were detected, which caused in a very short time, when exposed to the air, a coagulation of the whole fluid. This cyst fluid represents a blood transudate, and we might therefore name this tumor also a *serous cyst* (from a physiologicochemical point of view).

A SIMPLE APPARATUS FOR MODIFYING COW'S MILK.*

By CHARLES HERRMAN, M. D.,

NEW YORK.

A METHOD for the modification of cow's milk for the purpose of infant feeding should meet three important requirements: It should be fairly accurate; not too

*Presented to the Pædiatric Section, New York Academy of Medicine, February 14, 1900.

complicated; and it should admit of a number of changes of formulæ.

Of the methods suggested, those which are simple allow a very small number of changes in the percentage of the various ingredients, and those which admit of a larger number of changes usually require the use of more or less complicated formulæ or tables.

In the construction of this apparatus I have made use of the data given in Dr. Holt's paper, recently published.*

Average cow's milk from a trustworthy dealer is taken as containing 3.5 per cent. of proteids, 4 per cent. of fat, and 4.5 per cent. of sugar. If such milk is allowed

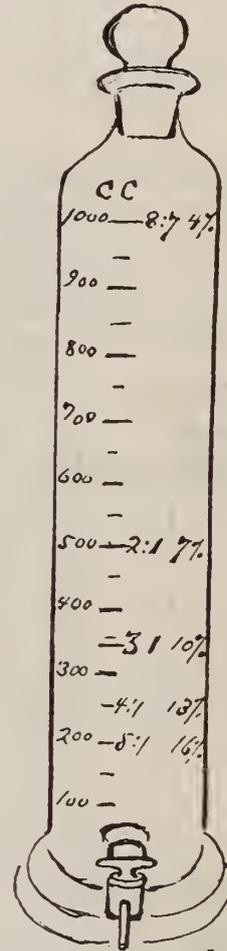

FIG. 1.

to stand for four hours (a longer time is not necessary) in a cool place, the cream separates, and we have:

Upper half: approximately, 7 per cent. fat, with fat to proteids as 2:1.

Upper one third: 10 per cent. fat—fat to proteids, 3:1.

Upper one fourth: 13 " " " " " " 4:1.

Upper one fifth: 16 " " " " " " 5:1.

The apparatus (Fig. 1) consists of a glass cylinder graduated to 1,000 cubic centimetres. (It is not necessary to remember the equivalents of drachms and ounces in the metric system.) The use of 1,000 cubic centimetres greatly simplifies the calculation. At the bottom

*New York Medical Journal, January 12, 1901.

there is a stop-cock, so that the milk may be allowed to flow off from below, instead of dipping or siphoning from the top. This has the advantage that the separation can be made more rapidly and accurately, and the upper layer is not disturbed. The cylinder is graduated from below upward, so that it shows the amount of milk remaining in the vessel. At 1,000 cubic centimetres it is marked 8:7, 4 per cent., that is to say, fat to proteids, 8:7, 4 per cent. fat; at 500 cubic centimetres,

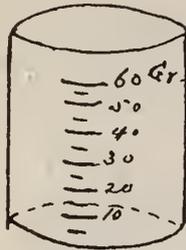

FIG. 2.

2:1, 7 per cent.; at 333 cubic centimetres, 3:1, 10 per cent.; at 250 cubic centimetres, 4:1, 13 per cent.; at 200 cubic centimetres, 5:1, 16 per cent.

The apparatus is used as follows: If a mixture containing fat to proteids as 3:1 is desired, after the cream has separated, the lower portion of the milk is allowed

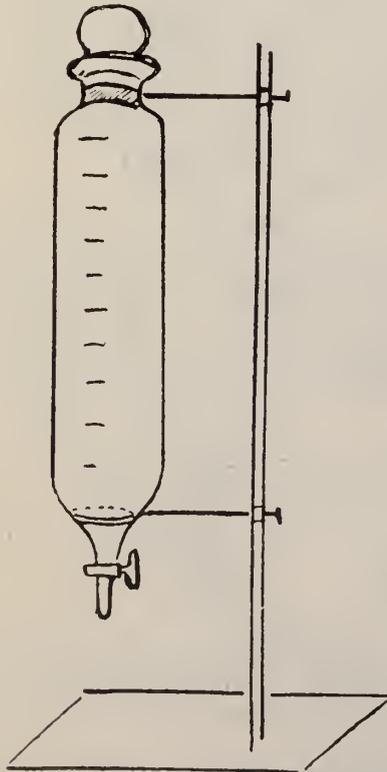

FIG. 3.

to flow out, until the milk remaining in the vessel has reached the point 3:1, 10 per cent. It is then mixed. This gives a mixture containing fat to proteids 3:1 fat, 10 per cent.

To determine the number of cubic centimetres of this mixture to be used, divide percentage of fat de-

sired by percentage of fat in the mixture, and express the result in hundreds. For example, if 2 per cent. fat is desired, we have:

$$\begin{array}{r} 10) 2. \quad ; \text{ if } 2.5 \text{ per cent., } 10) 2.5 \quad \text{etc.} \\ \hline 200 \text{ c. c.} \qquad \qquad \qquad 250 \text{ c. c.} \end{array}$$

In this case the divisor being 10, no calculation is required; the desired percentage expressed in hundreds is taken. If we wish to add 5 per cent. of lime water, add five divisions (each division represents 1 per cent.). Then fill to 1,000 cubic centimetres with the diluent, boiled water, barley water, or gruel, whichever is chosen.

If a mixture containing fat to proteids as 2:1 is desired, after the cream has separated, the lower portion is allowed to flow off until the point marked 2:1, 7 per cent., is reached. The milk is then mixed as before. We have then a mixture containing fat to proteids as 2:1, 7 per cent. fat. As before, to determine the number of cubic centimetres to be used, divide the percentage of fat desired by the percentage of fat in the mixture, and express in hundreds. For example, if 3 per cent. of fat is desired, we have:

$$\begin{array}{r} 7) 3. \\ \hline 428 \text{ c. c.} \end{array}$$

The same method is used for the fats to proteids, as 8:7, 4:1, and 5:1, the divisor in these cases being 4, 13, and 16, respectively.

In this way it is possible to obtain any number of changes in the amount of fat and proteids, in the relations of 8:7, 2:1, 3:1, 4:1, 5:1, without remembering or referring to any formula. The only number needed, the divisor, 4, 7, 10, 13, 16, is marked on the vessel.

With regard to the percentage of sugar, by referring to Table I it will be seen that the sugar is to the proteids

TABLE I.

Fat to proteid, 5:1=	fat, 16	per cent.;	proteids, 3.20;	sugar, 4.05
" " " 4:1=	" 13	" " "	" 3.25	" 4.15
" " " 3:1=	" 10	" " "	" 3.30	" 4.30
" " " 2:1=	" 7	" " "	" 3.40	" 4.40
" " " 8:7=	" 4	" " "	" 3.50	" 4.50

in a nearly constant ratio of 1.3:1. Therefore, to take a simple example, if any of the above mixtures contains 1 per cent. of proteids, it will contain 1.3 per cent. of sugar. If we wish 5 per cent. of sugar, 3.7 per cent. must be added, *i. e.*, 37 grammes for 1,000 cubic centimetres; if 6 per cent. of sugar is desired, 4.7 per cent., or 47 grammes. For measuring the desired amount of sugar, a small graduated glass (Fig. 2) is used.

Incidentally the apparatus may be used for testing the quality of the milk used. The specific gravity of a specimen of the whole milk is taken. After standing, the percentage of cream may be read off directly, as each space represents one per cent. Then the specific gravity of a portion of the lower milk, which has been allowed to flow off, is taken. The specific gravity of the whole

milk from a herd ranges from 1,029 to 1,033 at 60° F. The specific gravity of the lower milk should be from 2.5 to 3.5 greater than that of the whole milk, and the percentage of cream from 15 to 18.

A somewhat different form of the same apparatus is shown in Fig. 3. Here a separatory funnel is used. The graduations and method of using are the same.

27 WEST ONE HUNDRED AND FIFTEENTH STREET.

Therapeutical Notes.

Rhus Glabra in Enuresis.—Dr. J. J. Cassidy (*Canadian Journal of Medicine and Surgery*, February) reports three cases of nocturnal enuresis in boys of from twelve to fourteen years of age, in which other treatment had proved unavailing, successfully treated as follows:

℞ Citrate of iron.....160 grains;
Syrup of lactophosphate
of lime,
Aromatic syrup of cas- } of each. 2 ounces.
cara,

M.
A teaspoonful after dinner (noon).

℞ Fluid extract of rhus glabra....320 minims;
Syrup.to 2 ounces.

M.
A teaspoonful at bedtime.

This treatment was continued for four months. The incontinence disappeared and has not since recurred. The author says that rhus glabra produced more than a temporary effect, and adds:

“My explanation is that this remedy was given regularly for four months, and the cure resulted largely from the continued action of the vegetable astringent on the vesical mucosa, and particularly the fibres of the sphincter vesicæ. The use of iron as an adjuvant to rhus is important; but, the mineral being incompatible with a vegetable astringent, it was given in a separate prescription. Aromatic syrup of cascara was combined with it to overcome its constipating action.

“The syrup of the lactophosphate of lime is useful in relieving atonic and irritative dyspepsia, which in some cases of enuresis may be responsible for a disordered and irritating condition of the urine, such as lithæmia and oxaluria. The restoration of the urinary secretion to a normal condition tends to make the bladder more tolerant, and thus by lessening irritation of the vesical mucosa promotes the cure of enuresis. All the authorities say that rhus should be given three times a day, and iron is usually given as often. Each of the mixtures I ordered was given once a day, so that in my cases the results were as favorable as they could have been if they had been used more frequently.”

A Prescription for Mumps.—Dr. Floyd M. Crandall, in Vol. ii of the second edition of Hare's *System of Practical Therapeutics*, says of the following mixture that it is palatable and renders good service during the febrile stage:

℞ Spirit of nitrous ether..... 2 fluid drachms;
Solution of ammonium acetate.... ½ fluid ounce;
Glycerin. ½ “ “
Cinnamon water, enough to make.. 3 fluid ounces.

M. A teaspoonful every two hours for a child five years old.

A Lotion for Painful Dentition.—The *Medicinisch-chirurgisches Central-Blatt* for February 8th credits the following formula to the *Correspondenz-Blatt für schweizer Aerzte*, 1900, No. 23:

℞ Citric acid, } each..... ⅓ of a grain;
Distilled water, }
Cocaine hydrochloride. 1½ grain;
Syrup. 5 drachms;
Tincture of vanilla.....10 drops.

M. To be rubbed on the gums.

Methyl Salicylate in the Painful Nocturnal Erections of Gonorrhœa.—Baratier (*Deutsche Aerzte-Zeitung*, 1900, No. 23; *Medicinisch-chirurgisches Central-Blatt*, February 8th) advises warm baths, copious draughts of vichy water, and anointing the penis with the following ointment:

℞ Methyl salicylate. 1 part;
Petrolatum. 10 parts.

M. After the inunction a thin layer of wadding should be applied to the member, and the whole covered with adhesive taffeta.

An Enema for Eclampsia.—Popescul (*Semaine médicale*, 1900, No. 49; *Fortschritte der Medizin*, February 13th) recommends the following formula as particularly efficient:

℞ Potassium bromide, } each. 120 parts;
Chloral (hydrate?), }
Extract of hyoscyamus, } each. 1 part;
Extract of cannabis indica, }
Distilled water. 360 parts.

M. A tablespoonful to be injected into the rectum before or during the paroxysm.

A Powder for Anorexia.—*Progrès médical* for January 19th credits Kalb with the following formula:

℞ Crystallized quassine. ⅓ of a grain;
Powdered nux vomica..... ⅓ “ “
Powdered rhubarb. 2½ grains.

M. Such a powder, in a wafer, to be taken before each meal.

An Ointment for Chapped Hands.—Steffen is credited with the following formula in the *Journal de médecine de Paris* for January 20th:

℞ Menthol. 3 parts;
Salol, } each. 4 “
Olive oil, }
Lanolin. 100 “

M. S. To be applied twice a day. It is said that the pain disappears, the skin softens, and the fissures heal promptly.

A Palliative for the Pain of Gastric Cancer.—The *Klinisch-therapeutische Wochenschrift* for February 10th gives the following formula as emanating from Dieulafoy, of Paris:

℞ Cocaine hydrochloride. . . . ⅓ of a grain;
Morphine hydrochloride. . . . 1 “ “
Lime water. 3 fluid ounces.

M. S. A coffeespoonful in a tablespoonful of ice-cold milk every hour. At the same time an ice bag should be applied to the epigastrium. After the second day the dose may be diminished gradually.

To Soften Wax in the Ears the following has been found generally useful:

℞ Sodium biborate. 2 grains;
Glycerin. ½ a drachm;
Water to. 2 drachms.

THERAPEUTICAL INJECTIONS OF SOLIDIFYING
FATS.

Not long ago, when the endomeningeal employment of cocaine for purposes of anæsthetization was making a stir, we called attention to the fact that, fifteen years before, Dr. J. Leonard Corning had fully described the procedure in our columns. We regard it as not a little remarkable that we should so soon have fresh occasion to allude to an ingenious device of Dr. Corning's that had passed unnoticed. In our issue for April 14, 1894, Dr. Corning described what he termed *elæomyenchysis*, which he had practised successfully for the relief of obstinate painful spasm affecting one of the large muscles of the neck, the *splenius*. It consisted in injecting into the substance of the muscle a melted mixture of hard paraffin and cacao butter in such a way that, when the fat cooled, a number of solid transverse bars would be formed in the muscle, considerably restricting its power to contract. The idea was certainly worthy of imitation, but, though it had effected the purpose in Dr. Corning's case, it appears to have met with no imitators until quite recently.

Now, however, some of our Austrian colleagues have been resorting to injections of fat, but for a far different purpose, that of mitigating incontinence of urine in women. At a meeting of the *Kaiserliche königliche Gesellschaft der Aerzte in Wien*, held on February 15th (*Wiener klinische Wochenschrift*, February 21st), Kapsammer reported three cases in which he and von Frisch had cured incontinence by a procedure which he attributed to Gersuny. We do not know when Gersuny's work in this direction was done or where the original account of it is to be found. The injections were made into the tissue between the anterior vaginal wall and the neck of the bladder, "white vaseline" (probably hard paraffin) being used. In two of the cases von Frisch

injected six cubic centimetres of the fat twice, at intervals of a week; in the third case Kapsammer made only one injection, using eight cubic centimetres. In one of von Frisch's cases the patient complained of tenesmus and of the sensation of a foreign body in the rectum immediately after the injection, and her temperature rose to between 100° and 101° F. The other patient had a chill, headache, dyspnoea, an irritative cough, and a rise of temperature to 100.56° F. At the same time she complained of a severe stabbing pain a little to the left of the apex of the heart. All these symptoms, however, soon subsided. In Kapsammer's own case there were no untoward symptoms, and he attributes their absence to the fact that he injected the entire amount of the paraffin at one point. The theory of the operation is that the paraffin, as it hardens, forms a mechanical support which assists the vesical sphincter somewhat as the enlarged median lobe of the prostate impedes micturition in the male subject. Whether or not this theory is well founded, the efficiency of the procedure is beyond doubt.

There is a danger connected with this mode of treatment, and it is that of giving rise to pulmonary embolism, which actually occurred in a case of Pfannenstiel's, though, fortunately, not with a fatal result. Kapsammer thinks the danger is proportionate to the number of punctures made, but Gersuny, in the discussion, gave it as his belief that it was in direct proportion to the melting point of the fat employed. We have no doubt that Gersuny is right in this. Corning, too, had the danger of pulmonary embolism in mind, and he guarded against it by securing the immediate solidification of the fat by chilling the part with a spray of ether. The failure of the Austrian operators to take a similar precaution seems to show that they were unacquainted with Corning's original procedure. In vaginal work an ice-bag might be applied over the seat of puncture, but we fancy that limiting the spread of the injection by compression of the surrounding parts would prove more convenient.

THE MEDICOLEGAL VALUE OF FLORENCE'S TEST
FOR SPERMINE.

THE medicolegal value of Florence's reaction for spermine, like that of all reagents, depends, of course, upon its conclusiveness. Florence's reaction, as we chronicled in our issue for July 16, 1898, consists in the fact that, if to some fluid supposed to be spermatic fluid, or to some supposed spermatic stains upon linen, etc., previously moistened with water, a few drops of the

following reagent are applied, there immediately ensues the formation of dusky-brown microscopic crystals, partly long rhombic tables and partly fine needles. These crystals closely resemble hæmin crystals.

The reagent, called potassium triiodide, is prepared by dissolving in 30 parts of water 1.65 parts of potassium iodide and 2.54 parts of iodine (previously washed). Now, it is certain that this reaction is, on the whole, fairly constant in the presence of spermatic fluid; but much more than this is requisite before it can be permitted to assume any definite scope in medicolegal investigations. This test has been re-examined separately by Gumprecht, Richter, Lecco, and others; now comes Dr. Duquenne with an investigation carried on under the direction of Professor Corin in the Institute of Legal Medicine of the University of Liège, and published in the *Annales de la Société de médecine légale de Belgique*, xii année, No. 3. The questions which Dr. Duquenne proposed to himself were: 1. Do seminal stains, after submission to certain manipulations, still continue to give Florence's reaction? 2. Is the reaction specifically confined to sperm stains, or is it also presented by other substances? 3. Is the action specific to human spermine, or, better still, only to ejaculated human spermine; or may it also be determined by the sperm and testicular products of other animals? 4. Does the reaction actually possess in the presence of human spermine the value assigned to it by Florence, viz., that it serves to separate spermatic from non-spermatic stains, so that, when obtained prior to the search for spermatozooids themselves, if the crystals appear, the search for spermatozooids may be prosecuted with almost a certainty of finding them; while, on the contrary, if the crystals do not appear, it will be vain to search for spermatozooids which are certainly absent? 5. Finally, what is the principle in the seminal fluid which determines the production of the crystals in the presence of potassium triiodide?

To answer these questions, the author made a series of experiments. In regard to the first, he soaked for two months rags containing sperm stains, after previously satisfying himself of the presence of spermatozooids and of Florence's crystals, in alcohol at 40°, sulphuric ether, water, and water with potash soap and with hydrochloric acid respectively, chloroform, and petroleum ether. All traces of Florence's reaction disappeared except in the case of the last two.

He further found that crystals, either identical with, or closely resembling, those of Florence's reaction, were

obtained by the reagent from a great number of substances—*e. g.*, sulphate of atropine, tincture of cantharides, pyridine, iodide of N methyl pyridine, picoline, ecgonine, glyocol, and Pochl's spermine; but piperidine, methyl piperidine, piperazine, and glandular secretions from the vagina, uterus, and nasal cavity gave no reaction. Preparations of the testicle and prostate treated by Brieger's method and then submitted to the triiodide test did not give distinct crystals when recent; but after standing for some twenty-four hours crystals were obtained. From this and the last series of experiments, it follows that the formation of the crystals is not characteristic of spermine.

The author further found that certain stains on the linen of both men and women, while clearly giving evidence of spermatozooids, failed to form crystals with the triiodide, though the same solution was shown to be active with other specimens. This failure is, however, admitted to be exceedingly rare and its determining causes unknown.

The investigations into the nature of the substance in the sperm which determines the production of crystals were fruitless, though the author considers that the idea that the crystals are due to something in the reagent itself may be discarded.

From all these considerations it seems clear that but little reliance can be placed upon this test save as confirmatory evidence, and that, until more definite results can be obtained, it cannot with safety be relied on for medicolegal purposes.

INTERNATIONAL RECIPROCITY IN TEACHING.

THE brilliant clinical demonstrations given in various European cities many years ago by the late Dr. J. Marion Sims, the work of the late Dr. Brown-Séguard and Mr. Lawson Tait in New York, and Sir Michael Foster's more recent lectures in San Francisco, all raise the thought that something done more systematically in this direction would prove powerfully conducive to a most desirable diffusion, not so much of actual knowledge, as of breadth of view, among the medical men of various countries. To a considerable extent, the international medical congresses work to this purpose, but, so far as the element of personal intercourse is concerned—and that is the particular element that we have in mind—they reach only physicians whose ideas have already been more or less irrevocably formed, those who have reached mature years. What is perhaps of greater importance is that a like influence should be brought to

bear upon those whose minds have not yet emerged from the formative stage—that is to say, upon undergraduates.

As regards the actual increment constantly going on in the knowledge of medicine, it is continually diffused over the world by the periodicals, as everybody knows, but book knowledge of what has been accomplished by certain men and of what investigations they are at work upon does not rank with the appreciation that comes from hearing a man talk, even in a foreign language, noting his mannerisms, and witnessing his manipulations. Who can doubt that the element of personal "magnetism" counts for much more than the written word? Certainly nobody who has worked under the late Mr. Lawson Tait. It is no disparagement to Mr. Tait's writings to say that they fall far short of his personal teaching. Doubtless the same may be said of Trousseau's work and of that of Sir Thomas Watson, charming as their writings are. Moreover, there are men of great influence on contemporary thought who do little or no writing. A conspicuous example was the late Dr. Alonzo Clark. From such facts as these proceeds the great value of the didactic lecture. If, once a year, each of our leading medical colleges could afford to its students a course of lectures by some commanding thinker from another city, how would the young men's grasp of the actual status and the potentialities of medicine be strengthened!

Some of our leading universities appear to have made a beginning in the work of providing for special courses of lectures by distinguished men who are not members of the faculty, and our impression is that the example set by one of the medical schools of San Francisco will not only be kept up by that particular institution, but also spur on other schools to a similar course. First one country and then another produces a man of towering eminence as a teacher; his usefulness should not be confined to his own land, and still less should it be restricted to a particular institution.

THE DESTRUCTION OF THE ORANGE (N. J.) ISOLATION HOSPITAL.

IT is difficult to imagine anything more discreditable and reprehensible to all concerned than the work of the mob that demolished the isolation hospital in Orange, N. J., on March 11th. But, apart from the fact that recourse to mob law is a stigma of barbarism, one would think that rational people in any community would see that a hospital for infectious disease is far less dangerous to its environment than even one sporadic

case of such disease in a private house. In the former case, knowledge, methods, appliances, etc., are all at hand, and are used under strict regulations, for minimizing the dangers of the disease and preventing its spread; while in the latter instance, in some cases all, in all cases some, of these things are inevitably lacking. We commend this consideration to the notice of the Orange Common Council, upon which, as we understand, may devolve the duty of authorizing a new hospital.

OXYURIDES IN A MEDICOLEGAL ASPECT.

A CURIOUS case appears in a recent number of *L'Indépendance médicale*, culled from a report by Professor Lacassagne in the *Archives de l'anthropologie criminelle*. A woman had been murdered, and in her bed was found some faecal matter deposited by one of the presumed murderers. Examination of this matter showed the presence of some twenty female oxyurides. It so happened that of six persons arrested on suspicion, four of them accused a particular one as the murderer, and volunteered the information that he had also defæcated in the victim's bed. M. Lacassagne, therefore, made a careful examination of the rectal contents of the six suspects, repeated several times at intervals, with a negative result in the case of the five; but in that of the one accused by his fellow suspects, the examination showed him to be affected with oxyurides, thus confirming the testimony of the others. The moral of this Sherlock-Holmes-like story is that no detail, however trivial, should escape consideration in criminal medico-legal investigations.

IS THE OCCURRENCE OF HERNIA AN ACCIDENT?

WE do not know how the accident insurance companies answer this question, but we hope that an answer in the negative is not likely to be sustained by the courts, although it was recently upheld by Butruille at a meeting of the Central Society of Medicine of the Department of the North (*Indépendance médicale*, January 2d), who defined an accident as an injury due to an external cause, involuntary and instantaneous—meaning, we presume, that the exertion was involuntary. He was speaking particularly of the occurrence of a hernia.

THE DANGER OF CERTIFYING ON HEARSAY.

A DOCTOR'S good nature occasionally leads him to trust, to his detriment, in the word of another, but rarely, we imagine, to the extent that occurred recently in the case of a French physician who, according to the *Temps* (cited in *Progrès médical* for February 9th), certified that a certain woman was insane without ever having seen her. This he did on the strength of statements made to him by the woman's nephew, who was also her debtor. The aunt was put into an asylum, but her sanity was soon established, and the doctor was fined \$400 for his part in the affair.

News Items.

Society Meetings for the Coming Week:

MONDAY, March 18th: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.
 TUESDAY, March 19th: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.
 WEDNESDAY, March 20th: Medico-legal Society, New York; Northwestern Medical and Surgical Society, New York (private); New Jersey Academy of Medicine (Newark).
 THURSDAY, March 21st: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.
 FRIDAY, March 22d: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.
 SATURDAY, March 23d: New York Medical and Surgical Society (private).

Marine-Hospital Service Health Reports:

The following cases of smallpox and yellow fever were reported to the surgeon-general during the week ending March 9, 1901:

Smallpox—United States.

Mobile, Alabama.....	Feb. 23-Mar. 2.		1 death.
San Francisco, California.....	Feb. 18.....	8 cases.	
Washington, District of Co-			
lumbia.....	Feb. 23-Mar. 2.	7 cases.	
Jacksonville, Florida.....	Feb. 23-Mar. 2.	3 cases.	
Cairo, Illinois.....	Feb. 16-23.....	6 cases.	
Ottumwa, Iowa.....	Feb. 2-9.....	1 case.	
Lawrence, Kansas.....	Feb. 23-Mar. 2.	2 cases.	
Wichita, Kansas.....	Feb. 23-Mar. 2.	12 cases.	
Lexington, Kentucky.....	Feb. 23-Mar. 2.	2 cases.	
New Orleans, Louisiana.....	Feb. 23-Mar. 2.	7 cases.	2 deaths.
West Bay City, Michigan.....	Feb. 22-Mar. 2..	5 cases.	
Winona, Minnesota.....	Feb. 23-Mar. 2.	12 cases.	
Omaha, Nebraska.....	Feb. 22-Mar. 1..	5 cases.	
Manchester, New Hampshire..	Feb. 23-Mar. 2.	27 cases.	
Elmira, New York.....	Feb. 23-Mar. 2.	1 case.	
New York, New York.....	Feb. 23-Mar. 2.	64 cases.	11 deaths.
Yonkers, New York.....	Feb. 22-Mar. 1..	1 case.	
Charlotte, North Carolina....	Feb. 1-28.....	16 cases.	
Ashtabula, Ohio.....	Feb. 23-Mar. 2.	2 cases.	
Cincinnati, Ohio.....	Feb. 22-Mar. 1..	2 cases.	
Toledo, Ohio.....	Feb. 23-Mar. 2..	3 cases.	
Youngstown, Ohio.....	Feb. 23-Mar. 2.	2 cases.	
Allegheny, Pennsylvania.....	Feb. 23-Mar. 2.		2 deaths.
Philadelphia, Pennsylvania....	Feb. 23-Mar. 2.	1 case.	
Pittsburgh, Pennsylvania.....	Feb. 23-Mar. 2.	4 cases.	
Memphis, Tennessee.....	Feb. 23-Mar. 2.	16 cases.	
Nashville, Tennessee.....	Feb. 23-Mar. 2.	17 cases.	
Salt Lake City, Utah.....	Feb. 23-Mar. 2.	31 cases.	
Huntington, West Virginia....	Feb. 23-Mar. 3.	1 case.	

Smallpox—Foreign and Insular.

Hong Kong, China.....	Jan. 15-22.....	1 case.	
Liverpool, England.....	Feb. 8-16.....	2 cases.	
London, England.....	Feb. 8-16.....	1 case.	
Dundee, Scotland.....	Feb. 8-16.....	6 cases.	
Glasgow, Scotland.....	Feb. 15-22.....		20 deaths.
Vera Cruz, Mexico.....	Feb. 19.....	300 cases.	
Yucatan, Mexico.....	Feb. 20.....	Epidemic.	
St Petersburg, Russia.....	Feb. 2-9.....	4 cases.	1 death.
Warsaw, Russia.....	Jan. 26-Feb. 2..		8 deaths.
Jaffa, Turkey in Asia.....	Jan. 1-15.....	Epidemic.	

Yellow Fever.

Havana, Cuba.....	Feb. 17-24.....	3 deaths.
-------------------	-----------------	-----------

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending March 7, 1901:

BERRY, T. D. Assistant Surgeon. Detailed as quarantine officer at the port of Cienfuegos, Cuba.
 BROWN, B. W., Passed Assistant Surgeon. Directed to report at Washington, for special temporary duty.

CLARK, TALIAFERRO, Assistant Surgeon. Granted seven days' extension of sick leave from March 8th.
 GOODMAN, F. S., Hospital Steward. Relieved from duty at Havana, Cuba, and directed to proceed to Washington and await orders.
 LONG, J. D., Assistant Surgeon. Relieved from duty in the Hygienic Laboratory, Washington, and directed to proceed to New York, and report to Surgeon L. L. WILLIAMS, Immigration Depot, for duty.
 MACDOWELL, W. F., Hospital Steward. Granted leave of absence for thirty days from March 20th.
 NEWBERN, WALTER, JR., Hospital Steward. Granted leave of absence for thirty days from March 5th.
 NYDEGGER, J. A., Passed Assistant Surgeon. To assume temporary command of the Cape Charles Quarantine Station during the absence of Assistant Surgeon C. W. WILLE.
 PERRY, T. B., Passed Assistant Surgeon. Granted leave of absence for thirty days from March 12th.
 TROTTER, F. E. Assistant Surgeon. Relieved from duty as quarantine officer at the port of Cienfuegos, Cuba.
 WILLE, C. W., Assistant Surgeon. Granted leave of absence for seven days from March 4th.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending March 9, 1901:

DISEASES.	Week end'g Mar. 2.		Week end'g Mar. 9.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	23	11	22	12
Scarlet Fever.....	541	30	562	32
Cerebro-spinal meningitis.	0	0	0	0
Measles.....	167	8	274	8
Diphtheria and croup.....	293	36	261	44
Small-pox.....	64	11	54	10
Tuberculosis.....	267	161	320	170

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending March 9, 1901:

EAKINS, O. M., Assistant Surgeon. Detached from the *Ajax*, when put out of commission, and ordered home to await orders.
 HUNTINGTON, E. O., Assistant Surgeon. Detached from the *Bennington* and ordered to the *Newark*.
 KENNEDY, R. M., Passed Assistant Surgeon. Detached from the *Newark* and ordered to the *Bennington*.
 PAYNE, J. H. JR., Assistant Surgeon. Detached from duty at Pollock, P. I., and ordered to the *Isla de Cuba*.
 SNYDER, J. J. Assistant Surgeon. Detached from the *Isla de Cuba*, and ordered to Pollock, P. I., with marines.
 SPEAR, R., Passed Assistant Surgeon. Detached from the *Buffalo* and ordered to the *Isla de Luzon*.
 STONE, M. V., Assistant Surgeon. Detached from the *Isla de Luzon* and ordered to the *Buffalo*.

Indiana Objects to Christian Scientist Practices.

—The Indiana legislature has passed a bill requiring all persons practising medicine or the art of healing to take examinations and be licensed. This is aimed at the Christian Scientists.

Chicago's Lowest Death Rate for any February on record was that recorded for the past month, of a little over fourteen per thousand. The even, though low, temperature of the month is assigned as the probable cause of the improved health of the community.

New Yellow Fever Serum.—Dr. Las Casas, of Santos, Brazil, who has discovered a serum which he believes will cure yellow fever, is about to begin experiments to test it. The Medical Association of Rio Janeiro has appointed a commission to assist in the tests.

Fire in a Hospital.—About midnight on March 8th fire was discovered in the top floor of the Eastern District Hospital of Brooklyn, but through the prompt and

efficient work of the nurses and attendants with buckets the fire was held in check until the arrival of a chemical engine, when it was extinguished.

The Jenner Medical College.—Dr. Gustavus M. Blech has been appointed professor of casualty surgery in this college. This is the first institution in the West to establish a chair for this branch of practical surgery and medicine.

Dr. Busey's Will.—The will of Dr. Samuel C. Busey has been filed for probate at Washington, D. C. To the executor of his will is left his medical library, instruments, etc., in trust, to be presented to some public hospital or medical association in the District.

A Lady Physician Decorated by King Edward VII.—The *Lancet* for February 23d states that Miss Lillie Emma Vahine-é-tua Saville, L. S. A. Lond., M. D. Brussels, of the London Mission, has received from the king the decoration of the Royal Red Cross in recognition of services at the International Hospital during the siege of the legations at Peking.

American Charity on the Riviera.—Mrs. Pierre Lorillard, Jr., is planning to build an immense sanatorium on the Riviera for consumptive American women of small means. It is said that, under the guidance of Mme. Severine, Mrs. Lorillard has adopted socialistic views, and will devote her wealth and influence to promoting the cause among society women.

Site for Sanitarium Purchased.—Dr. J. B. H. Janeway, of New York City, has purchased a block of thirty-seven building lots at Burns Point, Conn. He intends to erect a large sanitarium. The land bought overlooks Long Island Sound. It is about a furlong in width and half a mile in length. Dr. Janeway says that he will erect a dozen cottages besides the main building. The land cost Dr. Janeway about \$20,000.

New York's Quarantine against Cuba.—Dr. A. H. Doty, health officer of the port of New York, has been in Washington, D. C., in direct consultation with Surgeon-General Wyman, of the Marine-Hospital Service, regarding the quarantine laws for the coming summer. The general plan of last year will be followed. It is said that a quarantine against Cuba will be declared next month.

The College of Medicine of the University of Iowa Burned.—The College of Medicine and literary buildings at the University of Iowa were destroyed by fire on March 10th. The loss is not less than \$250,000. Both buildings were burned in two hours. A severe blow was struck to the university on account of the loss of recitation rooms. The College of Medicine will close in three weeks and arrangements have been made to carry on the work.

Philadelphia Declares Consumption Contagious.—Consumption has been placed on the list of contagious diseases by the Philadelphia board of health. Physicians must now report to the health officer all cases and deaths. It is not the intention of the board to isolate victims of the disease. The work is to be purely educational. It will consist in offering advice in regard to precautionary methods. Medicines and disinfectants will be supplied to worthy poor patients.

Health of the Army in the Philippines.—A report from Colonel Greenleaf, chief surgeon of the Division of the Philippines, dated January 15th, which has just been received at Washington, shows that at that time the strength of the command was 67,415, and the percentage of sick was 7.49. The consolidated weekly report of hospitals in Manila and the military hospitals in the Division shows 2,400 sick. There were 83 deaths among the troops during the month ended January 15th.

Medical Library News.—The will of Dr. Abbott Hodgman, recently filed for probate in the office of the surrogate, leaves his library to the Academy of Medicine of New York city.—The medical and surgical library of the late Dr. William Pierson, of Orange, N. J., numbering 2,000 volumes, has been presented by Mrs. Pierson to the physicians of the Oranges, and they have decided to organize the William Pierson Medical Library Association.

Lecture by Mr. Reginald Harrison.—Mr. Reginald Harrison, F. R. C. S., the well-known authority on genito-urinary diseases, delivered an address on Some Retrospects and Prospects of Genito-urinary Surgery at the Cornell University Medical School, in this city, on Wednesday afternoon, March 13th. The audience was a large one, including many leading practitioners, and the speaker was very cordially received. The address will be printed in full in an early issue of the *New York Medical Journal*.

The University Medical Magazine.—The title of this periodical has been changed with the March issue to *University of Pennsylvania Medical Bulletin*, and changes have also been effected in the make-up. It is now printed in double instead of single column, and advertising matter has been excluded. No change, however, it is said, is to take place in the policy and scope of the journal, which continues to be the official organ of the medical department of the University of Pennsylvania.

Bellevue Hospital Nurses to be Tried.—The trial of Clinton L. Marshall and Edward O. Dean, the Bellevue Hospital nurses accused of causing the death of Louis H. Hilliard, the Frenchman, in the insane pavilion of the hospital, has been set down for March 19th. The motion pushing the trial of Marshall and Dean after Davis, the other nurse implicated, was acquitted, was a surprise, but it was said by a representative of the district attorney's office that there was some strong testimony which was not utilized at the Davis trial and which would be used against the other two nurses.

Hawaii Objects to Seekers after Health.—The authorities of Honolulu and the Hawaiian Islands have determined that the great increase in the death rate from tuberculosis during the past year is due to the importation of the disease. A bill has been prepared and will be brought before the territorial legislature prohibiting the landing at any port in the Hawaiian Islands of any person suffering from consumption or other form of tuberculosis, or other contagious or infectious disease. Since the annexation of the islands there has been an exodus of patients from the mainland. Any person who advises such persons to settle in the island, or who aids or abets their landing there, will be considered guilty of a misdemeanor.

Poisoned by External Application of Mercuric Iodide.—A coroner's jury in Allegan, Mich., has found a verdict that a young man, nineteen years of age, came to his death from the effects of poisoning by red iodide of mercury applied to his body in the form of an ointment. The poisonous ointment was prescribed by a physician and put up under his personal supervision.

A Minnesota Health Board Resigns.—The members of the board of health of Anoka, Minn., recently tendered their resignations. The trouble arose over the city council refusing to pay bills contracted by them. The health board claims the right, by law, to furnish necessities to persons under quarantine, who are unable to aid themselves, but the council thinks differently. Hence the trouble.

New York State Civil Service Examinations will be held about March 23d at twenty-eight different points in the State, full particulars of which may be obtained by applying to the chief examiner of the State civil service commission, Albany, N. Y. Among the vacancies to be filled are those of physician, junior grade, the usual salary being \$900 annually, with maintenance, and optical surgeon, with a salary of \$25 to \$40 per month.

Unna's Prize for 1900 was not awarded, no worthy thesis having been submitted. For this reason the sum to be awarded in 1901 has been increased to 600 marks. This sum will be awarded for the most meritorious original investigation submitted to Voss, the Hamburg publisher, by December 1, 1901, upon the subject of the minute structure of primary epithelial carcinoma, and more particularly that of the relation between epithelial proliferation and the resistance of the connective tissue.

To Deprive Pasteur Institute of State Appropriation.—Assemblyman R. Gardiner, of Monroe county, has introduced a bill into the New York State legislature which deprives the Pasteur Institute of its annual State appropriation of \$6,000, and hereafter levies the expense of the maintenance of patients sent thither by the overseers of the poor of counties on these various counties. Under the provisions of the measure, it is said, the scope of the institution will be considerably lessened.

New Jersey Anatomy Students Must Have Two Years at College.—A bill has been presented in the New Jersey legislature by Assemblyman Lewis prohibiting any institution that gives instruction in human anatomy from graduating pupils in less than two years. The bill is aimed at the Mechano-Neural Therapy School, conducted at Trenton. The managers of this institution advertise to teach their system of curing without drugs in ten months, and because they do not prescribe drugs in any way the school is exempt from examination by the State board of medical examiners.

Medical Legislation in Missouri.—The lower house of the Missouri legislature, after an almost all-day discussion, has passed the Hall bill, regulating the practice of medicine, and which has been construed as affecting the Christian Scientists, by a vote of 82 yeas to 42 nays. It provides that all practitioners of medicine, surgery and midwifery, all who claim to heal diseases, shall stand an examination before the State Board of Health as to their qualifications, irrespective of diplomas, and obtain

from the board a certificate to practise. The law is not applicable to those now engaged in practice.

A Physicians' Orphan Home Association has been organized with a view to founding a home for the indigent orphan children of physicians. An option has been obtained on a suitable building at Bristol, Tenn., with eighty-five rooms, and the committee state that if they can obtain subscriptions to the amount of \$35,000 the institution can be opened at once. The officers are: President, Dr. G. M. Pravlee, Bristol, Tenn.; vice-president, Dr. N. H. Reeve, Bristol, Tenn.; treasurer, Dr. John Anderson, Holston Bridge, Va., and secretary, Dr. John S. Harris, Minor Hill, Tenn.

Boston Health Officers Visit New York.—Edwin W. Pilsbury, health commissioner of Boston, accompanied by Dr. Jordan, chief sanitary inspector, and by Dr. Alexander Burr, chief veterinary surgeon of the Boston health department, spent several days inspecting the sanitary aspects of different districts in this city recently. The tour of inspection, which was carried out under the guidance of Dr. Feeney, chief sanitary inspector of the health department of this city, embraced the lodging-houses, Bellevue Hospital, the morgue, the tenement houses of the lower East Side, the markets, and the new tunnel, with a view to learning what arrangements had been made as to interrupted sewer connections, etc.

Typhoid in Brooklyn.—An unusually large number of cases of typhoid fever have been reported in the Williamsburg district of Brooklyn recently. In two rooms of a tenement house seven members of one Russian family were found ill with the disease.

Vaccination Notes.—About 500 persons per day are being vaccinated in Denver, Col., and practically no opposition has developed.—The annual report of the chief health officer of Pittsburgh shows that during the year ending January 31st he vaccinated 1,901 persons and issued 2,302 vaccination certificates. Most of the cases of small-pox treated occurred among, or were traceable to, negroes coming from the South.—Thirty doctors vaccinated 2,000 persons in four hours in Greenpoint, Brooklyn, recently.

Small-pox.—Following the discovery of eleven cases in two rows of houses in a tenement district in Brooklyn came discoveries of a similar nature in other parts of the borough. The spread of the disease in this city has been very rapid and the increase in the number of cases in the past month has been over double that of the preceding month. Not only is this true, but the type of the disease is more virulent than it was in the beginning. Other recently infected places are Toronto, Ont., and Kansas City, Mo.

The Plague.—Up to November 17th, according to the *British Medical Journal*, fourteen cases of plague and five deaths have been reported in Cape Town. The returns for all India for the week preceding January 1st show 3,396 deaths as compared with 3,277 for the previous week. Sporadic outbreaks have occurred in the province of Astrakan, while several cases have been reported near Smyrna and one death has been recently reported at Constantinople. Fourteen fresh cases of plague and ten deaths were reported in Mauritius during the week ending February 14th.

San Francisco's Bubonic Plague.—A conference held at Washington, D. C., on March 9th, between California commissioners and Secretary Gage, Assistant Secretary Spaulding, and Supervising Surgeon-General Wyman, of the Marine-Hospital Service, relative to the alleged existence of bubonic plague in San Francisco, has resulted in a definite plan of procedure. The clash between the State authorities and the Federal government has virtually been settled, and Secretary Gage insists that Surgeon-General White, of the hospital service, who is now in San Francisco, shall have charge of the measures taken to stamp out the plague. The Federal authorities believe that for the present a rigid individual isolation of the cases of suspected plague in Chinatown will be sufficient. Neither the State nor the whole city will be quarantined unless conditions change for the worse.

The Richmond Academy of Medicine and Surgery.—At the last regular meeting, on Tuesday evening, the 12th inst., the subject for discussion was a paper on Cyclic Albuminuria, by Dr. W. A. Deas.

The Foundation of Jenner Societies to combat the influence of the anti-vaccination societies has been proposed by Dr. C. A. Young, secretary of the Maryland State Board of Health, in a letter to the health commissioner of the city of Baltimore.

The Kentucky State Medical Society will hold its forty-sixth annual session in the city of Louisville on May 22d, 23d and 24th. Full information regarding the meeting may be obtained from the chairman of the committee of arrangements, Dr. Louis Frank, Louisville.

The Banquet of the Austin Flint Medical Society.—The Austin Flint Medical Society of Pittsburgh had its tenth annual banquet recently. Dr. J. C. Stein acted as toastmaster, and responses were made by Dr. M. C. Cameron, Dr. W. H. Snively, Dr. Stewart Patterson and Dr. J. C. Dunn.

The Sherbrooke Medical Society.—At the annual meeting of the Sherbrooke Medical Society, at Sherbrooke, Quebec, the following officers were elected: President, Dr. F. J. Austin; vice-president, Dr. J. O. Camirand; secretary-treasurer, Dr. E. J. Williams; council, Dr. W. D. Smith, Dr. L. C. Bachand and Dr. J. A. M. Elie.

The Louisiana State Medical Society will hold its next annual meeting at the medical department of Tulane University on April 18th, 19th, and 20th. The committee of arrangements have issued a preliminary programme, a copy of which may be obtained by applying to the corresponding secretary, Dr. A. G. Friedrichs, New Orleans, La.

The Annual Meeting of the Western Ophthalmologic and Oto-laryngologic Association will take place in Cincinnati on April 11th and 12th. Dr. C. R. Holmes, of Cincinnati, is chairman of the local committee of arrangements. Dr. M. A. Goldstein, of St. Louis, is the president, and Dr. W. L. Ballenger, of Chicago, is the secretary of the association.

The Queens-Nassau Medical Society.—The midwinter meeting of the Queens-Nassau Medical Society was held recently at Long Island City, when a paper was

read by Dr. George Donohue, of Northport, on The Advantage of Immediate Repairs on Lacerated Cervices, and one by Dr. C. G. J. Finn, of Hempstead, on Fæcal Fistulæ following Appendectomy. A general discussion followed upon the management of typhoid fever.

The Northeastern Ohio Union Medical Association held its one hundred and eighteenth quarterly meeting in Akron, O., on February 12th, and the following officers were elected for the year: President, Dr. G. L. Starr, of Hudson; first vice-president, Dr. George S. Peck, of Youngstown; second vice-president, Dr. A. E. Foltz, of Akron; recording secretary, Dr. J. H. Seiler, of Akron; corresponding secretary, Dr. C. W. Milliken, of Akron; treasurer, Dr. H. H. Jacobs, of Akron. The next meeting will be held in Canton.

The Banquet of the Alpha Chapter of the Phi Chi Southern Medical Fraternity.—The third annual banquet of the Alpha chapter of the Phi Chi Southern Medical Fraternity took place at Baltimore on March 11th. Responses to toasts were made by Dr. J. T. McCarty, Dr. W. A. B. Sellman, Professor Melvin, Professor Theodore Cooke, Jr., Professor Fred C. Jewett, Professor E. Miller Reid, Professor H. H. Biedler, Mr. Daniel A. Shay, Professor J. W. C. Cuddy, Mr. William J. Bauman, Dr. William D. Bacon, Professor Z. K. Wiley, Dr. Frank J. Powers, Professor Benjamin A. Hayden, Mr. William J. Kavanagh, and Mr. Walter J. Cathrall.

Cincinnati Academy of Medicine Election.—The annual election for officers of the Academy of Medicine of Cincinnati, O., was held recently. Dr. N. P. Dandridge was elected president, defeating Dr. George B. Orr, the West End Medical Society's candidate. Following is the result of the contest: Dr. N. P. Dandridge, president; Dr. A. B. Isham, first vice-president; Dr. Horace J. Whitacre, second vice-president; Dr. Stephen Cone, secretary; Dr. A. Carson, librarian; Dr. Louisa Southgate, corresponding secretary; Dr. M. A. Tate, financial secretary; Dr. Samuel E. Allen, treasurer; Dr. E. Gustav Zinke, Dr. C. R. Holmes, and Dr. John Healy, trustees.

Boston City Hospital Alumni.—The Boston City Hospital Alumni met recently, with John H. McCollom, president, in the chair. Addresses were made by Dr. D. W. Cheever, who spoke on Medical Education; Dr. G. W. Gay, who spoke on the Practice of Medicine in Egypt; Dr. George B. Shattuck, who spoke on Medical Journalism; Dr. J. L. Hildreth, of Cambridge, on Hospitals in Sister Cities; Dr. Abner Post, on Past and Present of Surgery; and Dr. Paul Thorndike, on Modern Surgery. The following-named officers were elected: Dr. W. E. Boardman, president; Dr. W. A. Morris, vice-president; Dr. W. H. Robey, Jr., secretary; Dr. W. H. Prescott, treasurer; Dr. T. E. Goldthwait, to the executive committee for five years.

Reunion of Pennsylvania University Medical Fraternity.—The University of Pennsylvania chapter of the medical fraternity, the Alpha Mu Pi Omega, held a reunion recently in Philadelphia, about eighty members and guests being present. The toastmaster of the evening was Dr. Edward L. Duer, and toasts were responded to as follows: "The University," Provost Harrison; "The Past of the Fraternity," Dr. R. G. Curtin; "Athletics," Dr. Edgar F. Smith; "The Profession,"

Dr. James B. Walker; "Our Brothers in Law," George Wharton Pepper; "Teaching," Dr. Alfred Stengel; "The Future of the Fraternity," Dr. Thomas H. Fenton; "Undergraduates," Daniel M. Hoyt. Dr. Edmund W. Holmes also spoke briefly. Among the guests were Dr. S. Weir Mitchell and Thomas Darlington, of Kingsbridge, N. Y.

The Baltimore County Medical Association.—The February meeting of the Baltimore County Medical Association was held recently at the Baltimore, Md., Medical College. Dr. H. Burton Stevenson is president; Dr. R. C. Massenburg, corresponding secretary, and Dr. H. S. Jarrett, treasurer. Addresses were made by Dr. L. M. Allen, Dr. L. Gibbons Smart, Dr. H. B. Stevenson, and Dr. B. F. Bussy. Dr. R. C. Massenburg read a tribute to the memory of Dr. S. C. Tomay.

The New York Academy of Medicine.—The monthly meeting of the New York Academy of Medicine will be held at 17 West Forty-third Street, New York city, on Thursday evening, March 21st, at 8 o'clock. A symposium will be presented on the modern treatment of gonorrhœa and its complications and sequelæ, the following papers being promised: Acute Gonorrhœa, by Dr. G. K. Swinbourne; Chronic Gonorrhœa, by Dr. John Van der Poel; The Complications of the Anterior Urethra, by Dr. M. J. Echeverria; The Complications of the Posterior Urethra, by Dr. J. Pedersen; Gonorrhœal Complications, by Dr. W. A. Holden; Gonorrhœal Stricture of the Urethra, by Dr. J. R. Hayden. The papers will be discussed by Dr. R. W. Taylor, Dr. R. Guitéras, Dr. B. Lapowski, Dr. C. H. Chetwood, Dr. E. Fuller, Dr. F. Bierhoff, Dr. Hill, and Dr. C. L. Gibson.

County Organizations of the New York State Medical Association.—The following county associations, members of the New York State Medical Association, have been organized: On January 22, 1901, the Westchester County Medical Association was organized, the following officers being elected: President, Dr. N. J. Sands, of Portchester; vice-president, Dr. J. L. Porteous, of Yonkers; secretary and treasurer, Dr. D. T. McPhail, of Purdy Station. Dr. E. F. Brush, Dr. H. Eugene Smith, Dr. P. J. Sands, and Dr. McPhail were elected members of the various committees required by the by-laws of the State association. On the 12th of February the Orange County Medical Association was organized, with Dr. M. C. Conner, of Middletown, as president; Dr. F. W. Dennis, of Unionville, as vice-president, and Dr. C. I. Redfield, of Middletown, as secretary and treasurer. Dr. C. Townsend, Dr. R. A. Taylor, Dr. W. E. Douglas, Dr. F. D. Myers, Dr. Joseph B. Hallett, Dr. William Evans, Dr. Charles A. Canfield, Dr. Edward Woodhull, Dr. Henry B. Swartwout, and Dr. E. A. Nugent were elected members of the various committees. The Sullivan County Medical Association was organized on February 19th with the following officers: President, Dr. C. S. Payne, of Liberty; first vice-president, Dr. Frank Howser, of Centerville Station; second vice-president, Dr. S. W. Wells, of Liberty; secretary, Dr. J. L. C. Whitcomb, of Liberty, and treasurer, Dr. C. W. Piper, of Wurtsboro.

To Establish a Hospital for the Insane in New York.—Dr. Henry, the chairman of the Assembly committee on public health, has introduced a bill to provide for the establishment of a hospital for the treatment of acute

mental and nervous diseases in the city of New York, to cost not more than \$3,000,000, and appropriating \$250,000 for its maintenance.

A Consumption Sanatorium for New Jersey.—A number of prominent New Jersey physicians, together with Dr. Flick, of Philadelphia, and Dr. Knopf, of New York, appeared at Trenton on March 11th to urge the joint appropriations committee of the New Jersey legislature to make provision for the construction of a sanatorium for the treatment of consumption. Senator Hutchinson, of Mercer, has introduced a bill calling for the expenditure of \$50,000 in the building of such an institution.

Hospital Staff Changes.—Dr. John W. Foster, who left St. Elizabeth's Asylum at Washington, D. C., recently, to take charge of a hospital in Bangor, Me., has been succeeded by Dr. Benjamin R. Logie, formerly of the Manhattan State Hospital, New York. Dr. Logie was appointed to the position made vacant by Dr. Foster's resignation under the civil service regulations.—Dr. Ethan A. Nevin, of Ogdensburg, N. Y., has been appointed a junior physician at the Long Island State Hospital, at a salary of \$900 a year.—Dr. Charles M. Burdick, of Buffalo, has been appointed medical interne in the St. Lawrence State Hospital, at a salary of \$600 a year.—Dr. W. J. O'Donnell, formerly of the Emergency, Erie County, and State hospitals, Buffalo, N. Y., has been appointed an examiner in lunacy.—Dr. D. George Bodkin, who for eighteen months has been attached to St. Catharine's Hospital, New York city, has left that institution, his term having expired. Dr. Bodkin is a graduate of the College of Physicians and Surgeons, Manhattan. A banquet was tendered to him by the members of the hospital staff.

Staff of Buffalo's New German Hospital.—The new German Hospital of Buffalo was opened on March 11th. The staff selected is as follows: Internal consulting physicians, Dr. Courad Diehl, Dr. Emil S. Tobie, and Dr. Thomas Lothrop; attending physicians, Dr. H. C. Buswell, Dr. William Meisberger, Dr. Julius Ullman, and Dr. Robert Henenstreit. Consulting surgeon, Dr. Roswell Park; attending surgeons, Dr. M. Hartwig, Dr. Herman Mynter, Dr. J. G. Meidenbauer, Dr. Henry G. Bentz. Consulting physician in gynæcology, Dr. Matthew D. Mann; attending physicians, Dr. Charles H. W. Auel, Dr. Max Breuer, Dr. Herman E. Hayd, and Dr. Sigismund Goldberg. Consulting physician in obstetrics, Dr. Charles H. W. Auel. Diseases of children, Dr. L. Schroeter, Dr. Charles Weill, and Dr. H. C. Rooth. Diseases of the eye and ear—Consulting physicians, Dr. Lucian Howe and Dr. Julius Pohlman; attending physician, Dr. Jacob Goldberg. Diseases of the nose and throat—Attending physicians, Dr. G. F. Cott and Dr. W. S. Renner. Diseases of the skin—Consulting physician, Dr. Ernest Wende; attending physicians, Dr. Grover Wende, Dr. J. Kraus, and Dr. Alfred E. Diehl. Diseases of the genito-urinary organs, Dr. Alois Jokl and Dr. Julian A. Reister. Consulting and attending physicians in nervous diseases, Dr. W. C. Krauss, Dr. Floyd S. Crego, and Dr. H. G. Matzinger. Pathologists, Dr. W. G. Bissell, Dr. H. R. Gaylord, and Dr. J. A. Miller.

Hospital Buildings and Endowments.—The sum of \$25,000 has been appropriated, in addition to the \$20,-

000 already provided, for the alterations and repairs required by the Cumberland Street Hospital in Brooklyn.—An anonymous gift of \$15,000 has been made to the New York Post-graduate Hospital for the support in perpetuity of three free beds in the babies' ward.—St. Mary's Free Hospital for Children has purchased a plot measuring 25 by 100 feet on Thirty-fifth Street, New York, adjoining in the rear the property now occupied by the institution on Thirty-fourth Street.—The Harlem Medical Society and the Harlem Chamber of Commerce have united in protesting against the selection of the site at One Hundred and Thirty-sixth Street and Lenox Avenue for the location of the new Harlem hospital. It is asserted that the site first proposed at One Hundred and Twentieth Street and Lexington Avenue is more conveniently located, more healthful, and much less expensive than the Lenox Avenue site.—Plans have been approved for the erection of a five-story hospital building, costing about \$50,000, by the New York Medical College and Hospital for Women adjoining the college at 19 West One Hundred and First Street.—Plans have been filed in this city for a home for the nurses of the Presbyterian Hospital, to cost \$300,000. It will be an eight-story structure, to occupy 31 to 37 East Seventy-first Street. The new structure has been provided for financially through the efforts of the officers of the institution. The building will be absolutely fireproof and constructed of brick and limestone. There will be a complete gymnasium and all kinds of baths in the basement.—The board of estimate of New York city has set aside \$25,000 for the improvement of the Homœopathic Hospital, now a part of the Brooklyn charities department.—The Muhlenberg Hospital, Plainfield, N. J., has been tendered free of cost a site for the location of its proposed new building, with the proviso that no contagious diseases be treated in the hospital.—A movement is on foot looking toward the erection of a large general private hospital in Montreal on the site of the old Western Hospital. It is asserted by some that the methods in vogue in the private wards of the municipal hospital are open to criticism, and that the trouble can best be obviated by the erection of a private hospital, to which any physician may send pay patients with the assurance that his rights and wishes will be respected.—A small isolation hospital for small-pox is to be erected in Wilmington, Del.—A site for the proposed hospital for consumptives has been offered as a gift in West Roxbury, a suburb of Boston. The local opposition to the use of the Marcella Street Home for the purpose continues as strong as ever.—The Union Hospital of Lynn has been incorporated in Massachusetts and has purchased the Tapley estate in Linwood Road for hospital purposes.—John D. Rockefeller has subscribed \$5,000 toward the payment of the \$15,000 indebtedness of the Huron Street Hospital, Cleveland.—A provision in the will of Mrs. Love A. Palmer, of Ann Arbor, Mich., bequeaths \$35,000 to the University of Michigan for the benefit of the University hospital.—The sum of \$1,000,000 has been given to the Dunham Medical College, at Chicago, by John E. Du Bois, of Du Bois, Pa. The gift comes as an unsolicited testimonial for the benefits which his wife received recently in treatment by members of the faculty last fall. Mr. Du Bois is a multimillionaire lumberman and mine owner. He made the gift without any reservation, simply declaring that the money is at the disposal of the college authorities as soon as they have laid their plans for its disposition.—A. P. Johnson, of Chicago,

has donated \$1,000 to the Norwegian Lutheran Deaconess' Home and Hospital of that city toward a new building, which, when completed, will have cost \$100,000, and will be one of the finest of its kind in the city. Work will be commenced in about a month.—A plot of ground on Fifteenth Street, Philadelphia, which cost \$60,000, is shortly to be presented to the Hahnemann Hospital by George C. Thomas, of Drexel & Co.—A corporation has been formed, with a capital stock of \$50,000, to build a hospital in Oshkosh, Wis.—The will of Mrs. Marietta Hay, of Tarrytown, N. Y., bequeaths fifty-five shares of Chicago, Rock Island & Pacific and Ohio Railroad Company bonds to the Saratoga Hospital, Saratoga Springs, N. Y., and \$4,000 in bonds to the New York City Infirmary for Women and Children.—A bill has been introduced into the New York legislature to provide for a hospital for the treatment of acute nervous and mental diseases within the city and county of New York, at a cost not to exceed \$3,000,000, and to appropriate \$250,000 for its maintenance.

Births, Marriages, and Deaths.

Married.

BRIDGEMANN—JONES.—In Lacrosse, Wisconsin, on Thursday, March 7th, Dr. Henry M. Bridgemann and Miss Florence R. Jones.

COLTRIN—JEKYLL.—In Washington, on Monday, February 25th, Dr. Francis Delano Coltrin and Miss Annie Charlotte Jekyll.

Died.

ANDERSON.—In New Haven, on Friday, March 8th, Dr. William D. Anderson, in the sixty-fifth year of his age.

ARMSTRONG.—In Buffalo, on Monday, March 4th, Dr. J. Stone Armstrong, in the sixty-first year of his age.

CARR.—In Sedalia, Missouri, on Monday, March 4th, Dr. R. Wilson Carr, in the seventieth year of his age.

CLEMENT.—In Baltimore, on Sunday, March 3d, Dr. Albert W. Clement, in the forty-fourth year of his age.

CROUNSE.—In Clarksville, N. Y., on Friday, March 1st, Dr. Hiram Crouse, in the eighty-first year of his age.

DAVISON.—In Kenosha, Wisconsin, on Saturday, March 2d, Dr. William M. W. Davison, in the fifty-second year of his age.

DAWSON.—In Ottawa, Canada, on Saturday, March 2d, Dr. George M. Dawson, in the fifty-second year of his age.

DEWOLF.—In Halifax, Nova Scotia, on Tuesday, March 5th, Dr. James R. DeWolf, in the eighty-first year of his age.

GOLDSTEIN.—In Louisville, on Thursday, February 28th, Dr. Adolph Goldstein.

JOHNSTON.—In Gallipolis, Ohio, on Friday, March 8th, Dr. James Johnston, formerly of the United States Army, in the sixty-seventh year of his age.

LEONARD.—In Worcester, N. Y., on Wednesday, March 6th, Dr. William H. Leonard, in the sixty-sixth year of his age.

MORSON.—In Toronto, on Sunday, March 3d, Dr. Alfred Morson, in the ninety-first year of his age.

RILEY.—In Boston, on Monday, March 4th, Dr. Thomas Riley, in the fifty-eighth year of his age.

ROSS.—In Williamsburg, Pennsylvania, on Wednesday, March 6th, Dr. John Dean Ross, in the ninety-fifth year of his age.

SCHNIZLER.—In Philadelphia, on Thursday, March 7th, Dr. Emil Schnizler, in the sixtieth year of his age.

SHELDON.—In Bloomington, Illinois, on Monday, March 4th, Dr. John Sheldon, in the sixty-eighth year of his age.

SMITH.—In Syracuse, N. Y., on Friday, March 8th, Dr. Alonzo T. Smith, in the eighty-first year of his age.

STONE.—In New York, on Thursday, March 7th, Dr. Robert Stone, in the sixty-fourth year of his age.

SYLCURK.—In Frederick, Maryland, on Wednesday, March 6th, Dr. John Sylcurk, in the twenty-fifth year of his age.

THAYER.—In Newton, Massachusetts, on Tuesday, March 5th, Dr. Frederick L. Thayer, in the fifty-third year of his age.

WOODS.—In New York, on Friday, March 8th, Dr. Eliza Woods.

Pith of Current Literature.

Medical News, March 9, 1901.

Our Duties toward the Consumptive Poor. By Dr. S. A. Knopf.—The author points to the estimate of Dr. Herman M. Biggs, that this city has constantly at least thirty thousand cases of consumption, and that more than half of these are harbored in the worst tenement districts. The vast majority will die at an age when they should be bread winners and useful citizens. Consumption is not merely a medical, but also a social disease: Society must come to the aid of the physician. The author describes a typical visit to the tenement home of a consumptive, and he asserts that such a patient should not be allowed to live in such surroundings. According to the author, what are needed are multiple sanatoria and special hospitals of moderate size, located near the large centres of population.

The Intravesical Evidences of Perivesical Inflammatory Processes in the Female. By Dr. Frederic Bierhoff.

The Prevention of Insanity. By Dr. Henry Waldo Coe.—As a preliminary to the marriage of a healthy man to a recovered insane woman, the author advocates the removal of the ovaries, and he asserts that the sexual passion of the average woman, even with her ovaries, is of such trifling moment that ovariectomy need not on this account be largely considered. Fifty per cent. of insane people should never have been born, according to the author, and he holds physicians responsible to a certain extent for this mistake. He protests against large families; the ordeals of pregnancy, lactation, and the care of rapidly growing children are especially trying on the nervous and mental powers of the neuropathic mother, and a healthy woman in rapidly supervening pregnancies is less able in her offspring to offset an evil mental tendency on the part of her husband as such pregnancies are repeated.

The Tonometer and its Value in Determining Arterial Tension. By Dr. Henry L. K. Shaw.

The Present Status of the Subarachnoidean Injection of Cocaine for Anæsthesia (Corning-Bier Method). By Dr. John S. Miller.—The author's opinion is that this variety of anæsthesia should be used only when ether and chloroform are contra-indicated. It has a decided advantage, however, over general anæsthesia in that the respiratory, cardiac, and renal organs are not so seriously disturbed as by the inhalation method. The author submits that there is a medicolegal element in these "experiments," and he suggests that, in order to avoid the possibility of a suit for damages in case of accident or untoward results, it would be advisable to secure the absolute consent of the patient and family in writing or in the presence of witnesses, after explaining to them the merits and demerits of this procedure, which carries with it no small element of risk.

A Case of Peroneal Nerve-palsy from Muscular Effort. By Dr. Charles J. Aldrich.—The author echoes the observation of Hogarth, that, when we consider the exposed condition of the peroneal nerve, it is remarkable that it so rarely suffers injury.

Medical Record, March 9, 1901.

The Period of Incubation of Yellow Fever: A Study from Unpublished Observations. By Dr. Henry R. Carter.—In an extended series of observations, the

shortest incubation recorded is three days; the longest, eight and one quarter days; while very few of the cases show over six days. The author concludes that, while it may be that this question can be determined more readily simply by observing the time between the inoculation of the disease by an infected host and the development of the fever in the subject, yet it is well to compare the findings of observations on Nature's experiments with those from direct experimental research, for the first lack the precision of the latter in which we control all the conditions of the problem.

A Contribution to the Bottini Operation for the Radical Relief of Prostatic Obstruction. By Dr. L. Bolton Bangs.—A case given in detail illustrates the three points, in the way of technique, upon which the author lays stress. These are: (1) that the flow of electricity must be maintained to a degree that will keep the blade at white heat; (2) that, in measuring a given case for the length of the incisions, allowance must be made for the action of the galvanic cautery beyond the distance at which the knife shall actually penetrate; (3) that the operation must be done with great slowness in order to prevent hæmorrhage and to get the best results. In twenty per cent. of cases the operation was a failure. The author believes that the "extravesical" portion of the prostate, which cannot be reached by the galvanocautery, may be the cause of failure in these cases.

Acute Gastric Ulceration. By Dr. H. Newton Heineman.—The prognosis in these cases is exceedingly grave. In fifty cases of Savariand, in which hæmorrhage was the cause of death and in which autopsies were made, in one fourth, death was sudden by an overwhelming bleeding; in a second one fourth it occurred within from twenty-four to thirty-six hours after the first hæmorrhage; in the third one fourth, at the end of a week; and in the last one fourth, at the end of a fortnight. Until a repetition of the hæmorrhage has occurred and a count of the red blood corpuscles shows a serious diminution in their number, medical treatment should be tried. This should consist of absolute rest to body and stomach, with rectal alimentation, exclusively, for three or four weeks. An ice-bag applied to the stomach is useful, and intravenous or subcutaneous injections of serum should be used. In view of the fact that the first hæmorrhage may, by continuation, be fatal, or that the second may prove so, preparations for an immediate operation should be made. The author favors the procedure of Dr. Cazin as the one promising the best result, and the inversion of the gastric mucous membrane, careful absorption of the mucus by means of sterilized gauze, and a minute search with a pocket lens for the seat of ulceration should be made. When the diagnosis is promptly made and the ulcer is found at the operation, and the latter is timely, the prognosis ought to be good.

Treatment of Acute Sero-fibrinous Pleurisy. By Dr. Charles E. Nammack.—It is the author's belief that chest tapping should be performed in sero-fibrinous pleurisy for three indications: (1) when life is directly threatened or endangered by asphyxia from compression, or by cardiac weakness; (2) when fluid has risen to the third interspace in front, since experience has shown that effusions of this size rarely disappear spontaneously; (3) in all lesser effusions when spontaneous absorption is unduly delayed. In the absence of these indications the medicinal treatment should be studied; the local application of guaiacol or of iodine; internally, mild catharsis by sulphate of magnesium in concentrated so-

lution, with limitation of the ingested liquids to as low a point as possible, and the consumption of as much table salt as the patient can be induced to take. The author's experience seems to warrant the assertion that progress is more rapid in the cases not tapped.

Journal of the American Medical Association, March 9, 1901.

Sanitation and Progress. By Dr. Walter Wyman.—The author considers the present status of sanitation, and concludes that the outlook for the future is very bright. For the twentieth century there can be no more hopeful sign of progress than is held out by sanitation. Sanitation is a common field upon which nations may meet with unselfish and common purpose, a policy which would put a rifle-groove in the shotgun now loaded with spasmodic municipal reforms, good government clubs, and crusades against vice, and weld these latter into one missile of definite direction and force.

Results of Surgery in the Aged. By Dr. James P. Tuttle.—The author has had quite a large experience in this work among paupers, criminals, and vagrants, and, contrary to the prevailing impression, he finds that the mortality is very low and shock has been almost absent. The author's explanation is that when an individual has reached the age of sixty or seventy years, in comparatively good health, we must assume that he has either taken good care of himself and not undermined his constitution by dissipation and excesses, or that he originally had an exceedingly strong constitutional foundation to build on, and that he thus presents himself a suitable subject for operation.

Sarcoma of the Intestines, with Table of Fifteen Cases of Resection. By Dr. C. Van Zwalenburg.—This condition seems to be more common than the text-books indicate. The ileum appears to be its favorite location. Sarcoma rarely produces stenosis. Dilatation is more frequent. Usually the growth arises from one side of the bowel entirely. In the author's case, symptoms of obstruction were present, which were evidently due to a change in position of the freely movable tumor. It was entirely relieved by manipulation. The diagnosis is difficult and will always remain obscure; still, if a freely movable tumor is found in the abdomen, we should, unless it can be otherwise satisfactorily accounted for, be reminded of the probability of sarcoma of the intestine—especially if there is also present the general picture of sarcoma with its peculiar anæmia. The only treatment for the intestinal form is resection. We have a right to assume, in this connection, that in extirpating a sarcoma we remove a toxine-centre as truly as when we open an abscess.

Rest Treatment for Hysterical Disease. By Dr. John K. Mitchell.—The worse the case, the more satisfactory is this treatment, as a rule. Isolation is the most important feature of the treatment, and the more distinctly hysterical the disease, the more strict the isolation must be. In a moderately severe case, from six to eight weeks of isolation is enough. Massage has an important place in the treatment. Electricity is not regarded by the author as being of prime importance. The moral treatment, unlike the physical treatment, is different in each case and must meet the exigencies of each particular problem.

Hereditary Subnormal Color-perception. By Dr. F. Savary Pearce.—The author points out that Horner's law applies particularly to these cases. This law is to

the effect that sons of daughters whose father was color-blind are most likely to be the same, or "color-blindness is transmitted in the revertible type from grandfather to grandchild."

The Simplest Explanation of the Functions of the Nervous System. By Dr. G. W. Drake.—The author's explanation involves the interesting hypothesis of the existence of a specific energy peculiar to nervous tissue. Sound-waves, light, mechanical touch, odoriferous particles, sapid substances, under appropriate circumstances, liberate nerve energy, which is conducted to the auditory centre visual centres, etc., and there makes a neurograph of sound, sight, touch, etc.

Psychic Therapeutics. By J. C. Culbertson.

Treatment of Deflection of the Nasal Sæptum Complicated by Traumatic Deformity of the External Nose. By Dr. E. B. Gleason.

Extensive Laceration of the External Ocular Muscles; Diplopia; Spontaneous Recovery. By Dr. Walter L. Pyle.

Anastomosis of the Ureters with the Intestine. A Historical and Experimental Research. By Dr. Reuben Peterson.

Exstrophy of the Bladder. By Dr. F. Gregory Connell.

Acute Temporary Dilatation of the Heart Accompanying Thermic Fever. Report of Two Cases. By Dr. C. F. Close.

Rupture of the Membrana Tympani from Indirect Violence, with Concussion of the Labyrinth and Complete Deafness. By Dr. Richmond McKinney.

Philadelphia Medical Journal, March 9, 1901.

False Pregnancy (Pseudocycosis) and Myxœdema. By Dr. Edward P. Davis.—In diagnosing false pregnancy, the physician must not be misled by ectopic gestation. Examination under ether is of special value, as it enables the physician to map out the pelvic contents as accurately as possible. It is a mistake to allow patients having false pregnancy to go with an examination alone, without treatment. The source of nervous irritation giving rise to the supposed pregnancy should be removed, the nutrition of the patient stimulated as vigorously as possible, and her general condition brought as nearly to the normal as her circumstances permit. Where the patient can afford it, rest in bed, massage, careful feeding, electrical treatment, and a selected diet are indicated.

The Actions of Morphine upon Metabolism, with Special Reference to "Internal Secretion" and its Bearing upon Toxicology. By Dr. Edward T. Reichert.—The author considers that the profound depression of general metabolism, even by sublethal doses, together with the probable involvement of the processes concerned in internal secretion and in repair, and their consequent effects, must be considered among the important factors in the treatment of morphine poisoning. He believes that further research will show that we have in this depression an agent in explaining, in part at least, the values of certain physiological antidotes, and, on the other hand, the ineffectiveness of others which upon theoretical grounds should prove of signal power. If a means can be found to restore the normal processes concerned in internal secretion and in repair, the counteraction of the direct action of morphine upon the metabolic processes that are specifically engaged in the discharge of respiratory impulses, will probably be ac-

complished with far less difficulty than heretofore experienced.

Paresis Simulating Brain Tumor. By Dr. Wharton Sinkler.

Operative Treatment of Tubercular Lymphomata of the Neck. By Dr. Prescott Le Breton.

A Skiagraph of Bennett's Fracture of the Metacarpal Bone of the Thumb, or "Stave of the Thumb." By Dr. John B. Roberts.

A Cast and Skiagraph of the So-called Smith's Fracture of the Lower End of the Radius. By Dr. John B. Roberts.

On the Necessity for the Organization of Bacteriological Commissions for the Study and Investigation of Quarantinable Diseases under the Formation and Control of the Governing Authorities of the Countries Interested—An Absolute Necessity for the Scientific Management and Betterment of Maritime Hygiene and Quarantine. By Dr. Henry R. Horlbeck.

The Function and Distribution of Combined Hydrochloric Acid in Proteolytic Digestion. By Dr. A. E. Austin.

Boston Medical and Surgical Journal, March 7, 1901.

Clinical Notes and Comments: Cancer of the Extremity of the Common Bile-duct. By Dr. Robert T. Edes.—The author asserts that there can be but little doubt that cancer of the bile-duct is somewhat more common than would appear from some of the older statements, and he believes that many cases which would have been described as "obstruction" fifteen or twenty years ago have been brought by more careful microscopic methods under the head of carcinoma. He also speaks of the feasibility of an operation for the removal of cancer of the bile-duct, but he is careful to emphasize the fact that it is almost impossible to cut wide enough of any focus of cancer to be sure of having included the utmost limits of the infected region.

The Interpretation of Bacteriological Findings in Diphtheria Diagnosis. By Dr. Hibbert Winslow Hill.—It is pointed out that the board of health does not take the position that a sick person is necessarily suffering from the disease of diphtheria simply because a positive culture has been obtained. It insists, however, that such a person is a nucleus from which the bacilli may be spread, and remains such until the bacilli disappear. As to a negative report, four or five negative cultures should be obtained before a diagnosis of diphtheria is abandoned on bacteriological evidence alone.

Destruction of Left Eye and Frontal Lobe of Brain from a Shotgun Explosion. By Dr. Edward Swasey.

Convulsions in Children. By Dr. William N. Bullard and Dr. Charles W. Townsend.—One per cent. of the children applying at the Children's Hospital, Boston, come for convulsions. Ten per cent. of children between five and twelve years of age give a history of convulsions. Cases that appear to be due to some manifest reflex cause may turn out to be true epilepsy. Other cases, wherein the attacks occur frequently and without apparent cause, may suddenly recover, at least for a considerable period. Children who have had convulsions may be strong and free from nervous tendencies in later life, although the proportion of those who have nervous tendencies seems to be greater in them than in those who have not had convulsions.

Acute Pancreatitis. By Dr. M. H. Richardson.—The diagnosis of these obscure lesions is practically im-

possible. However, in all obscure inflammations of the epigastrium attended by acute sudden pain, we ought to explore. If we cannot do anything else, we can at least drain.

Case of Recovery after Operation for Acute Pancreatitis. By Dr. J. C. Munro.

Lancet, March 2, 1901.

Public Health and Housing: The Influence of the Dwelling upon Health in Relation to the Changing Style of Habitation. By Dr. J. F. J. Sykes.—In the Milroy Lectures for 1901, the author considers the effect produced upon the public health by the increasing density of population in cities and by the changes in construction of houses. Numerous statistical tables are given and conclusions drawn therefrom. In this, the first lecture, special attention is paid to the health of the inhabitants of stable dwellings, and the author concludes that the occupants of such premises have a high birth rate and a high mortality under one year, and at all ages high death rates from pulmonary and zymotic diseases, especially diarrhoea and diphtheria. These point to the vicissitudes of temperature affecting adults and unhealthy conditions at home affecting young children.

On the Influence of Ozone on the Vitality of some Pathogenic and other Bacteria. By Dr. A. Ransome and A. G. R. Foulerton, F. R. C. S.—The author's experiments go to show that ozone in the dry state has no appreciable action on the vitality of the various bacteria experimented with. Nor does a prolonged exposure to the action of ozone diminish in any way the pathogenic virulence of *Bacillus tuberculosis* in sputum. Single experiments tend to show that ozone can have little, if any, effect on the pathogenic virulence of *Bacillus mallei* and *Bacillus anthracis*. On the other hand, ozone possesses distinct bactericidal properties when passed through a fluid medium containing bacteria in suspension. This suggests a superficial resemblance with chlorine, sulphur dioxide, and other gases. So that any purifying action that ozone may have in the economy of Nature is due to the direct chemical oxidation of putrescible organic matter, and it does not in any way hinder the action of bacteria, which latter are, indeed, working toward the same end in their own way.

On the Quantitative Estimation of the Bactericidal Power of the Blood. By Dr. A. E. Wright.—In a previous communication in the *Lancet* for December 1, 1900, the author described the technique of a method by which the bactericidal power of blood could be determined. What is measured by this method is rather the total antibacterial power of the blood than the bactericidal power proper. To determine how much of the result registered is referable to an inhibition of the growth of the bacteria, and how much to a direct bactericidal action, it is necessary to blow out the contents of the incubated cultivation-tubes into sterile nutrient broth. Should any growth take place, it shows that the bacteria have only been inhibited in their growth, not destroyed. Where it is desired separately to estimate the bactericidal power, this can be done by making a series of graduated dilutions of a bacterial cultivation in broth, and by mixing one volume of each of these with one volume of serum. A convenient arithmetical expression for the bactericidal power is obtained by specifying the number of micro-organisms which one cubic millimetre of serum is capable of killing.

Result of Major Amputations Treated Antiseptically in the Royal Infirmary, Newcastle-upon-Tyne, during the Year 1899, and for a Period of Twenty-one Years and Nine Months—Viz., from April 1, 1878, to December 31, 1899, Inclusive. By H. B. Angus, M. R. C. S.—One thousand two hundred and thirty-three major amputations have been performed in the Royal Infirmary since 1878. Of these, 1,119 patients have recovered and 114 have died—a mortality of 9.2 per cent. Five hundred and eight cases were those of amputation for injury, and 71 patients died—a mortality of 13.9 per cent.; 725 were for disease, and 43 patients died—a mortality of 5.9 per cent.

A Method of Distinguishing Bacillus Coli Communis from Bacillus Typhosus by the Use of Neutral Red. By W. Hunter, M. B.—1. *Bacillus coli communis* possesses to a marked degree the power of reducing neutral red (safranin), producing a superb canary-yellow fluorescent color of the medium. 2. The so-called *Bacillus enteritidis* of Gaertner also produces this reaction, and is probably only a variety of *Bacillus coli communis*. 3. The *Bacillus typhosus* never possesses this power of reduction. 4. The common pathogenic micro-organisms do not give this reaction. 5. By means of neutral red it is possible within from twelve to twenty-four hours to diagnose with absolute accuracy the presence of *Bacillus coli communis*.

Note on a Case of Influenza with Meningitis as a Complication. By Dr. A. Foster.—The author reports the case of a woman, aged fifty-four years, in whom an attack of influenza was complicated on the fourth day of the disease by symptoms of meningitis. Severe headache was the first symptom, followed by muscular rigidity, retraction of the head, strabismus, and partial unilateral facial paralysis. The patient gradually failed, and she died on the sixth day. There appeared to be no doubt as to the diagnosis of influenza. For some weeks previously the patient had been greatly worried by family troubles.

Three Cases of Cervical Spina Bifida Treated as Out-patients by Open Operation. By J. H. Nicoll, M. B.

A Case of Fracture of the Sternum. By Dr. J. S. Martin.—The author reports the case of a miner, aged twenty-three years, who was crushed against a wooden upright by a passing truck, and his sternum fractured. There was definite projection of the manubrium sterni running vertically downward, and crepitus could be easily elicited. The fracture caused very little physical disability.

A Case of Cerebro-spinal Meningitis. By F. Riley, M. B.

Four Cases in which Pain was Relieved by Suprarenal Extract. By Dr. E. A. Peters.—The author reports four cases which show that the application of a suitable suprarenal extract may be of great benefit in allaying the pain of cancer and other forms of recurrent inflammation without any apparent deleterious effect. In one case of recurrent scirrhus of the mamma, with great pain in the growth, painting with ten-per-cent. suprarenal lotion relieved the pain almost entirely. A case of painful stricture of the œsophagus was benefited by the patient's sipping the same lotion; used as a spray in a case of tuberculosis of the larynx, the throat was rendered free from soreness for some hours. In the last case, one of periodontitis, pledgets of wool soaked in the ten-per-cent. suprarenal lotion and placed between the lip and the gum, gave great relief.

British Medical Journal, March 2, 1901.

Some Points Relating to Varicocele. By W. H. Bennett, F. R. C. S.—For practical purposes varicocele is merely varix of the veins of the spermatic cord, which is always congenital; to this is added in many cases some varicosity of the veins of the scrotum. The peculiarity (it cannot be called a disease) usually escapes notice until puberty, and, when noticed, it is most commonly discovered by accident, unless some injury has occurred to attract attention to it. As a rule, no trouble arises from the abnormality. From mental causes a considerable number of persons suffering from varicocele are led to seek treatment, and the majority of these are hypochondriacal. Operation affords a certain cure for the varicose condition itself, and should be recommended in cases of young individuals, healthy mentally as well as physically. In hypochondriacal cases, should the patient be fully convinced that if the varicocele is cured and the defect removed relief will follow, operation may be undertaken without hesitation. In about sixty per cent. of such cases in which the operation is attempted the patient is cured; in the other forty per cent. the treatment will fail. The author describes in brief detail the operation employed by him. An incision of from one half to three quarters of an inch—not more—is made over the cord on a level with the upper border of the root of the penis—that is to say, over the external abdominal ring. The whole of the spermatic cord, except the vas deferens, is pulled out of the wound (the veins not being laid bare), ligatures tied at either end, the intervening portion of the cord cut and removed, and the two stumps sutured together. Although the spermatic artery is thus removed, the vessels accompanying the vas deferens are sufficient to nourish the testicle. All fear of atrophy or gangrene may be dismissed.

Ad Terram. II. The Earth and the Soil. By Sir F. S. Haden.

The Influence of the Dwelling upon Health. By Dr. J. F. J. Sykes.—The first of the Milroy Lectures. (See abstract of the *Lancet* for March 2, 1901, in this number of the *Journal*.)

Painless Calculous Pyonephrosis without Fever; Nephrectomy; Recovery. By A. Doran, F. R. C. S.—The author reports a case of calculous pyonephrosis occurring in a woman aged thirty-eight years. For some months she had had a swelling in the right side, with nausea and epigastric distress, but never any pain in the swelling, and no fever. Examination of the urine was negative. At the operation the right kidney was found to have become a cyst, and was removed with great ease. The patient's recovery was uneventful. The kidney contained over half a pint of greenish-yellow pus. Two small calculi were found in separate loculi of the cyst. The absence of pain and fever were the remarkable features of the case. Langenbuch's incision was used at the operation, giving a clear view of the kidney and its relations.

The Treatment of Puerperal Eclampsia by Saline Diuretic Infusions. By Dr. R. Jardine.—This article is a short defense of the use of saline diuretic infusions in puerperal eclampsia. The author states that he has had greater success with this mode of treatment than with any other. In the Glasgow Maternity Hospital, the death rate in cases of puerperal eclampsia used to be forty-seven per cent.; since the use of saline diuretic infusions has been introduced, the death rate has fallen to seventeen per cent.

A Case of Puerperal Eclampsia and its Treatment by Morphine. By Dr. G. Elder.—The author reports a severe case of puerperal eclampsia occurring in a woman aged thirty-five years, in which the administration of one third of a grain of morphine hypodermically stopped the fits and produced two hours' sleep. No further medication was required, the patient's recovery being uninterrupted.

A Case of Multilocular Cystoma of the Omentum; Removal; Recovery. By N. P. Marsh, M. B., and K. Monsarrat, F. R. C. S. E.—The authors report a case of extensive cystic degeneration of the omentum occurring in a female child, aged one year and eight months. The child's abdomen had been enlarged for four months; it was tapped by means of a Southey's trocar four times between January and November, 1900, a large quantity of dark-brown fluid being removed each time. The fluid contained a large number of cholesterol crystals. Laparotomy was finally performed, and a large multilocular cyst removed. Recovery was rapid. The growth was probably congenital. The great vascularity of the cyst walls lends support to the suggestion of some inflammatory condition being associated with their origin, and such a process, antenatal, offers the most probable explanation of their ætiology.

The Campaign against Ague. By H. E. Durham, F. R. C. S.

Lyon médical, February 10, 1901.

Aerophagia and the Gastric Disturbances Accompanying It. M. B. Lyonnet and M. F. Vincens say that the voluntary swallowing of air is a physiological curiosity; involuntary aerophagia, however, is pathological and is due to hysteria. There is always a clonic spasm of the pharynx. Anorexia, pain, headaches, muscular asthenia, and general functional disturbances are frequent symptoms of the habit. The treatment is to be directed toward the general hysterical state, toward relieving the pharyngeal spasm, and toward the dyspeptic symptoms.

The Sanatorium of Hauteville. By M. J. Gentschel.

February 17, 1901.

Local and General Action of Cocaine.—M. Jaboulay finds that the local anæsthetic effect of cocaine is enhanced by the addition of morphine, the effect being more penetrating and more lasting.

Cholecystitis Resembling Appendicitis.—M. Adenot reviews the symptoms of acute and chronic appendicitis and cholecystitis and distinguishes between them. (*Continued article.*)

Severe Contusion of the Abdomen, Intestinal Rupture, Laparotomy, Cure. By M. Lagoutte.

Progrès médical, February 9, 1901.

Aspiration of Acute Prostatitis Occurring in the Course of Senile Hypertrophy of the Prostate.—M. A. Guépin advises this method when the acute prostatitis undergoes suppuration. He narrates six cases in proof of his assertion, in which normal urination followed aspiration of prostatic abscesses, all of them arising during the course of an hypertrophy of senile character.

Journal des praticiens, February 23, 1901.

Toxic Dyspepsia of Alimentary Origin in Childhood. By M. Sevestre.

Pathogeny of Biliary Lithiasis.—M. G. Linossier says that the discussion as to the pathogenesis of biliary lithiasis possesses only a theoretical interest. If the principal ætiological rôle is attributed to germs, intestinal antiseptics must be chosen as the main therapeutic agents. If, however, the patient's physical ten-

dencies and disposition are regarded as prominent in evoking the disease, diet, hydrotherapy, massage, and exercise will be the leading forms of treatment. The latter are in practice the more efficacious. The question will bear further inquiry and investigation.

Indépendance médicale, February 20, 1901.

Acute and Chronic Inflammation of Douglass's Pouch. By M. Leon Archambault.—The article is a review of the subjects of pelvic peritonitis and cellulitis, and contains nothing new.

Gazette hebdomadaire de médecine et de chirurgie, February 14, 1901.

Cytolysis of Cancer.—M. Louis Dor writes that the serum obtained from animals in the peritoneal cavity of which malignant tumors have been implanted, seems to exert a specific effect upon malignant tumors in the human species. This cytolytic action has been observed by the author in two cases of malignant inoperable sarcoma.

Presse médicale, February 6, 1901.

Treatment of Sphenoidal Empyema.—M. F. Furet says that in simple cases in which the nasal fossæ are large and the sphenoidal sinus accessible through them, the nasal route is to be chosen in opening an empyema of the sphenoidal sinus. When the maxillary sinus participates in the inflammatory process, when cerebral affections complicate the sphenoidal inflammation (not a common combination), and when the nasal fossæ are small or deformed—under these circumstances, the sphenoidal sinus should be attacked by the maxillary route by means of the trephine.

Wiener klinische Rundschau, January 27, 1901.

Stereoscopic Views of Röntgen-ray Pictures of Bones. By Dr. Max Reiner.

Two Cases of Ovarian Sarcoma.—Dr. Alexander Dörner reports two cases. One patient died of recurrence a few months after operation, the other has remained well for three years. The author says that the tumors in both cases developed from the matrix of the blood-vessels, not like angeio-sarcomata which represent vascular neoplasms, but from the endothelium of the blood-vessels, possibly of the lymphatic vessels.

Wiener klinische Wochenschrift, February 7, 1901.

Occupation Disease among Wood-turners.—Dr. Rudolf Blum describes a form of exudation of a greyish color on the nasal mucous membrane, with a swollen nose, some dyspnoea, and a pustular condition about the nostrils, as characteristic of workers in hazel wood. The fine dust evolved in the process of manufacture, he thinks responsible for the condition. It yields easily to ordinary measures.

Hysterical Facial Diplegia.—Dr. Hugo Lukacs describes such a case.

Foreign Bodies in the Male Bladder. By Dr. Fritz Pendl.—A clinical article.

Centralblatt für Chirurgie, February 9, 1901.

Injuries to the Soft Parts of the Knee-joint.—Dr. C. Lauenstein says that experience has shown the wisdom of aspirating effusions of blood into the knee-joint, not only the ultimate cure being hastened, but the ability of the patient to return soon to his work being facilitated. If a probe is gently introduced through the can-

nula by which the blood has been removed, and the interior of the joint gently palpated, one can frequently find the source of the hæmorrhage in a ruptured capsule. At the point of rupture the probe can be felt directly beneath the skin, which is not the case elsewhere in the joint. The Röntgen rays should be employed for the diagnosis of more extensive injuries to the knee.

Treatment of Patellar Fractures. By Dr. Popper.

Treatment of Contractures of the Knee-joint.—Dr. Carl Bruns reports two successful cases of transplantation of the biceps tendon upon the quadriceps tendon for the relief of contracture of the knee-joint, one of the cases being one of phlegmonous gonorrhœal arthritis. The operation is simple and free from danger, and the result is permanent.

Centralblatt für innere Medicin, February 9, 1901.

Fatty Degeneration of the Heart.—Dr. Georg Rosenfeld concludes, from an experimental and chemical study, that fatty degeneration of the human heart is the result of the deposit of fat in the intrafibrillary substance. The fibrillary substance undergoes actual degeneration only when a great, or too great, amount of fat is deposited within its folds; its death is the result of pressure from the large amount of fat. The fat is not a result of degeneration of the cardiac muscle, but is brought to the heart from other parts of the body.

Centralblatt für Gynäkologie, February 9, 1901.

Are Baths the Most Efficient Means of Cleansing Puerperal Women?—Professor W. Stroganoff says that the bath is not yet proved to be efficient in cleansing puerperal women. The water in the bath always contains the diluted dirt, and even the diluted excrement, of the person using it. If the individual has ulcers or sores, staphylococci or streptococci get into the water and may locate in other parts of the body, while the tubs may contain germs from previous bathers. Infection of the nipples, or even of the vagina, may thus take place. He prefers a rubbing with soap with a constant stream of water pouring over the patient. In the author's hospital service, the latter method of cleansing puerperal women has resulted in six months in a diminution of seven per cent. of morbidity.

Cure of Tuberculous Peritonitis after Laparotomy.—Dr. A. O. Lindfors believes that, by ligation of the tuberculous focus, the peritoneal irritation entirely disappears. This is due to the disturbed nutrition of the focus, just as the menopause may be induced by a double salpingectomy or ligation of the uterine arteries.

Riforma medica, January 14, 15, and 16, 1901.

A Contribution to the Bacteriology of the Blood in Acute Gastro-enteritis. By Dr. G. Pierraccini and Dr. Nencioni.—The conclusions of the authors are as follows: The symptoms which accompany intestinal indigestion are consequences of a toxæmia of gastro-intestinal origin, and not of a bacteriæmia. A bacterial invasion of the whole organism may only take place as the result of very severe alterations in the digestive apparatus.

January 17, 1901.

A Contribution to the Clinical and Semeiologic Study of Carcinoma of the Stomach. By Dr. V. Casaretti.—The author reports a case of carcinoma of the stomach which presented several interesting peculiarities. The patient was a man aged fifty-eight years, whose family history was unknown. He had been suffering from malaria since his twentieth year. On admission he presented the marked cachexia which accompanies cancer. He apparently preferred the supine

position, and complained of a severe pain in the epigastrium and left hypochondrium which was continuous, but markedly aggravated after meals. There was also salivation and a painful sensation in the mouth. On percussion, there was dulness at the lower portion of the left lung, especially below the angle of the scapula. On the left side of the epigastrium there was a slightly elevated area, and the superficial veins were enlarged to a marked degree over the upper quadrant of the abdomen, especially on the left side. Deep palpation produced acute pain in this region. A sensation of resistance, but no well-defined tumor, was felt in the left epigastric region, under the ribs. On percussion this zone was dull, the dulness being continuous with that of the spleen. A slight, soft-blowing murmur was repeatedly heard on auscultation between the semiclavicular and anterior axillary lines on the left side of the upper half of the abdomen. The spleen was slightly enlarged, but the liver was normal. The patient had nausea, absolute anorexia, and vomited frequently after meals. On examination, the gastric contents showed no traces of hydrochloric acid, but a distinct lactic-acid reaction to Uffelmann's test. The patient was soon unable to take anything except liquid food, and there was a severe and persistent diarrhœa. He died of exhaustion, with signs of œdema of the lungs. The necropsy showed old pleuritic adhesions on the left side of the chest, behind. The walls of the stomach were found transformed into a hard mass which was adherent to the spleen and to the transverse colon. The liver was congested (nutmeg liver in the second degree). On opening the stomach, no ulcerations were found, but a number of neoplastic masses were discovered in the wall, and on microscopical examination these proved to be infiltrated carcinoma of the stomach. The interesting part of this case is the possibility of mistaking it for a severe case of malarial cachexia with splenic tumor. The soft-blowing murmur which was described above has been met with in a number of malarial cachectics by Fedeli, of Rome. The explanation of this bruit is probably the compression of the vasa brevia which pass to the stomach from the splenic artery, and of the terminal branches of this artery which divide at the hilum of the spleen. According to Fedeli this murmur is due to anæmia and to vascular contraction. It is especially marked when anæmia is associated with a congestion of the spleen.

Vratch, January 20, 1901.

Corporal Punishments in the Twentieth Century.

By Dr. D. N. Jbankoff.—In spite of the fact that we have entered into the twentieth century, corporal punishment is still used in Russia, and the advocates of this form of penalty point with pride to the fact that in some of the western countries of Europe, where corporal punishment has long been abandoned, there have been, of late, attempts to restore this relic of barbarism. The desire to rule over the farm laborers is common to the landed proprietor in Prussia as well as Poltava. It is to be noted, however, that the German barons do not advocate corporal punishment for their own caste, but for the lower classes only. On the other hand, in Berne, there has come a project which provides that pupils in the public schools may be flogged for grave offences (*e. g.*, lying), at the request of their parents. The German Agrarians submitted a carefully worked out bill to the Reichstag, in which they plan to combine incarceration with flogging for all sorts of offences. The instrument to be used is a whip of leather, and the smallest number of blows is twenty-five. Still more sad, in the

author's opinion, is the proposition of the London *Lancet*, to the effect that all persons who are guilty of assault, highway robbery, etc., shall be flogged systematically. Some American authors and some American medical journals have gone even further, and recommended castration of all criminals.

In Russia, the use of the whip, and the abuse of the privilege of employing corporal punishments to "subdue" inferiors of all sorts, such as servants, hospital orderlies, and other "small fry," is flourishing as well as ever to-day. Peasants are flogged at the initiative of the local magistrate for nonpayment of debts. Another common cause of flogging is a complaint of an aged father, entered with the local magistrate or police officer, to the effect that the son can not be "managed." No witnesses are heard, and the "defendant" is not even allowed to speak for himself in many cases. These things are not really sanctioned by statutes, but are done quietly, the population taking such occurrences tacitly and regarding them as perfectly proper. The days of serfdom are still in the memory of many people. The effect of this is, that very often persons belonging to the classes of society which "may be flogged" for certain offences, according to Russian law, are beaten most inhumanly without the sentence of any court, simply because a person of this kind may be legally beaten. Thus prisoners are very often flogged at the police station before they appear in court, and the police employ their privilege of beating any one who offers resistance when arrested. Corporal punishment is also very often used in the elementary schools in Russia. (*To be continued.*)

The Hygienic Importance of Skin Diseases. By Dr. O. V. Peterson.—The author's conclusions are as follows: Affections of the skin are very prevalent in Russia. About one half of these patients suffer from local skin infections which are easily cured. The spread of knowledge concerning the laws of hygiene will diminish the number of cases of skin disease. The establishment of public baths is a very important factor in the prevention of skin diseases.

The Use of Injections of Cinnamate of Sodium in Tuberculous Subjects. By Dr. L. A. Finkelstein. (*To be continued.*)

The Determination of the Amount of Oxidizable Substances in Water by Means of Potassium Permanganate. By Dr. A. F. Drjevetsky.

Chirurgia, November, 1900.

Bullous or Hæmorrhagic External Otitis. By Dr. P. V. Ilyne.—The author describes a disease of the external auditory canal characterized by the formation of bullæ or swellings which completely occlude the lumen of the canal. In men, this disease is most frequent on the left side; in women, on the right. The canal is narrowed, so that examination of the membrana tympani is difficult. As a rule, the swellings are in the bony portion of the canal, and they are either perfectly transparent or dark-blue in color, and contain serum and blood. They may extend outward to the cartilaginous portion of the canal or inward to the ear drum. They are soft, elastic on probing, and may easily be ruptured. Pain, difficulty in hearing, and noises in the ears constitute the chief subjective symptoms. In one case there was delirium with delusions of persecution. The bullæ may be confounded with polyps of the middle ear, or with a bulging ear-drum at the beginning of an acute inflammation of the middle ear. Massage of the ear, according to Delstanchou, may give rise to such hæmor-

rhagic effusions, and in such cases the origin of the trouble will be determined on taking the history. The duration is short; the prognosis is good. At the outset an antiphlogistic treatment may be of value; but, if the bullæ have begun to form, it is best to open them, allowing the liquid to escape, and to pack the canal with cotton or gauze. In a few days the skin heals. If it does not, the site of the bullæ must be touched with some caustic or scraped with a sharp spoon to remove the granulations. The author reports three cases of this kind.

Chronic Perichondritis of the Auricle. By Dr. V. A. Svenitsky.—The author reports a case of this kind which he observed in a Cossack soldier in the campaign in Manchuria. The cause of the disease was a violent fall from a horse in full gallop, the Cossack falling so that his ear was compressed between the temporal bone and some hard substance. Suppuration followed, the perichondrium peeled off, and the inflammation assumed a chronic type, involving the entire external ear. The distinction between an affection of the skin only and of one involving the cartilage may be made without the aid of the microscope if the following clinical facts are considered: Perichondritis is present when there is a marked thickening of the external ear; when the ear feels softer in some places than in others, and when the skin adheres to the perichondrium and can no longer be moved over it as usual.

Fifteen Operations on the Stomach. By Dr. B. S. Kozlowsky.

The Symptomatology of the Joint Affections Accompanying Syringomyelia (Initial Stage of Arthritic Involvement). By Dr. P. D. Solovoff and Dr. S. S. Nalbandoff.

Journal Akouscherstva i Gienskich Boliesney, November, 1900.

The Results of Operations in Retroperitoneal (Post-cervical) Fibromyomas of the Uterus. The Significance of the Vaginal Method in Conservative Myomectomy. By Dr. D. Ott.—There is a group of fibromyomata of the uterus still considered as inoperable by the majority of gynæcologists. This group includes the fibromas that develop wholly outside the peritoneal cavity, in the retroperitoneal connective tissues. A type of these are the so-called postcervical fibromas, which, by their growth, destroy the normal anatomical relations of the peritonæum and surrounding parts, lifting the cul-de-sac of Douglas high up into the pelvis. These tumors occasion serious disturbances in the surrounding viscera, and also show a marked tendency to malignancy. As a rule, they are either not surgically treated or are merely scraped—a highly unsatisfactory procedure. The mechanical conditions accompanying the development of postcervical tumors are the worst possible for the organism. The tumor is wedged into the pelvis, the uterus pushed upward and forward, the vagina stretched, the urethra and the neck of the bladder are pressed against the symphysis pubis, the ureters displaced, and the rectum is compressed. If the tumor is large—and they sometimes reach the xiphoid cartilage—the vessels, nerves, and other structures in the abdominal cavity are also pressed upon. The author reports fifty-two cases in which he removed such retroperitoneal fibroids. In all these he had to open the peritoneal cavity to cut through the posterior leaf of the peritonæum, and then to enucleate the tumor from the

surrounding cellular tissue. After the removal of the tumor there remained a cavity in the retroperitoneal space, which he filled with a broad strip of sterilized gauze, the lower end of which was led into an opening in the vaginal vault, either specially made for it or remaining after a simultaneous vaginal hysterectomy. The peritonæum was carefully sutured over the cavity, thus cutting the latter off from the peritoneal space. By this method of tamponing the author succeeded in carrying to a favorable outcome cases of enormous fibroids, reaching to the xiphoid, behind the peritonæum. The abdominal wound was sutured completely and the vagina lightly tamponed with iodoform gauze. This tampon was renewed as often as it became saturated by the secretions that drained into the vagina along the gauze filling the cavity in the abdomen. In the fifty-two cases operated upon, there were only two deaths. These two patients were exhausted by disease and by previous unsuccessful operations, so that the conditions were unfavorable for recovery. The author emphasizes the advantages of the vaginal route in these operations, and states that, wherever possible, this method should be used, thus avoiding the risk of peritoneal infection. If the tumor is very large, it should be exposed below and removed piecemeal. On comparing his statistics, he found the vaginal method three times less dangerous than the abdominal operation.

A Historical Sketch of Obstetric Surgery. By Dr. M. Lachtine.

A Case of Myxoma of the Chorion Mistaken for Extra-uterine Pregnancy. By Dr. I. S. Kalabine.—The patient was a woman, aged twenty-nine years, multipara. During the fourth month of pregnancy she had a hæmorrhage, which lasted four days, disappeared, and reappeared at intervals during the succeeding month. At times clots were passed. Weakened by the loss of blood, the patient was obliged to remain in bed during the fifth month, and suffered from attacks of spasmodic pain in the lower part of the abdomen, the groins and the loins. In the sixth month a noted gynecologist made the diagnosis of extra-uterine pregnancy and recommended operation. The hæmorrhage continued. On examination, the author found the uterus enlarged somewhat beyond normal for the patient's stage of pregnancy. The cervix was slightly open. The right ovary was somewhat sensitive. The diagnosis of extra-uterine pregnancy was excluded, and the ovarian inflammation was found to be due to gonorrhœal infection. The softening of the uterine wall was not particularly marked and nothing pointing to myxomatous chorion or to myxomatous ovum was found in the hæmorrhages. A month later, the cervix admitted two fingers, the flow continued, and vesicles of myxomatous mass could be felt distinctly. The cervix was dilated with the fingers, the hand introduced into the uterus, and the new growth removed with the fingers; a lysol injection was given and ergot administered. Recovery was uneventful.

The author emphasizes the absence of softening of the uterus in this case, which led to a mistaken diagnosis of extra-uterine pregnancy, and then to one of threatening abortion.

Habitual Miscarriage and Habitual Premature Labor. By Dr. S. S. Cholmogoroff (*continued*).—The author's conclusions as regards the origin of the miscarriage and premature labor "habit" are as follows: In patients in whom no satisfactory explanation can be given for the occurrence of repeated miscarriages or

premature labors, mercury and iodides should be used during succeeding pregnancies in order to prevent such occurrences and to make the children healthy and strong. The same treatment is to be used where there is a history of syphilis in one of the parents. Neither iodides alone nor a carelessly conducted and insufficient course of mercurial treatment is efficient under these conditions. Such insufficient treatment can only postpone the labor and slightly increase the vitality of the fœtus. Often, antisiphilitic treatment conducted during one pregnancy will protect the mother and the offspring for one or more succeeding pregnancies; in other cases repetition is required at each pregnancy. In some cases the treatment must be repeated three times. Iodides should be used in the second pregnancy if the mixed treatment was successful in the first. At the beginning of the pregnancy one may give iodides to a patient who gives the history of repeated miscarriages, and when the critical period has passed, one may continue with mercury. Iodides may again be given at the end of the pregnancy.

Concerning the Duration of Pregnancy, Labor, and the Puerperal Period in Young Primiparæ. By Dr. N. P. Mariantchik.—The author's conclusions, based on very extensive statistical material, are as follows: Labor is not particularly unfavorable in women between the ages of sixteen and twenty years. While the duration of labor in such primiparæ is much longer, the frequency of important complications of labor is less, as, for instance, eclampsia, placenta prævia, post-partum hæmorrhages, and lacerations of the perinæum. It must be remembered, however, that a woman is only fully developed at the age of twenty years, and her pelvis becomes what it should be for the purposes of parturition, and her uterine musculature sufficiently strong to perform the required work. The occurrence of a greater percentage of miscarriages in young women may be interpreted as an effort of Nature to avoid the complications of labor when the apparatus of gestation and parturition is not fully developed. On the other hand, the children of such young mothers are distinguished by a lower vitality.

Letters to the Editor.

PUERPERAL SEPTIC DISEASES.

NEW YORK, March 2, 1901.

To the Editor of the New York Medical Journal:

SIR: In your issue of January 26th appears an article by Dr. H. J. Boldt on Septicæmia, Acute Bacteriæmia, etc. The article contains the following sentence: "This leads to confusion, especially when we see reports with such headlines as 'Acute Puerperal Septicæmia; Laparotomy; Removal of the Annexa; Recovery,' or 'Hysterectomy for Acute Puerperal Septicæmia Recovery.'"

The author had reference to my articles on the subject of puerperal sepsis which have appeared in various journals during the past three years. This fact was more clearly brought out by him when he closed the discussion which followed the reading of the paper before the New York Obstetrical Society, January 8, 1900, but which does not appear in the report of the proceeding of the society as published in your issue for February 16th, nor do the remarks made by me in the discussion excepting in a very meagre and imperfect manner.

I drew his attention then to the fact that I had never made use of the term "acute septicæmia" in the headlines of my papers. My astonishment was therefore great when I saw the article in print with the sentence in its original and incorrect form.

To set the matter at rest once for all time, I will herewith transcribe the headlines of all my publications on the subject: 1. Hysterectomy for Acute Puerperal Septic Metritis, with the Report of a Successful Case, *New York Medical Journal*, April 2, 1898. 2. Report of a Case of Salpingo-oophorectomy in Acute Puerperal Sepsis, *Medical News*, March 25, 1899. 3. The Surgical Treatment of Acute Puerperal Sepsis, with Special Reference to Hysterectomy, *American Journal of the Medical Sciences*, February, 1900; *Transactions of the American Gynecological Society*, 1899.

The subject of puerperal sepsis is of such paramount importance to the profession at large, and is of such interest to me, that I am constrained to make further criticism of the author's paper. I am pleased to see that Dr. Boldt has changed the views he held two years ago, when puerperal sepsis was the subject of discussion between us. At that time he held that hysterectomy was never indicated in acute puerperal sepsis. In his present paper he lays down similar indications to those which I set in my first paper, without giving me any credit for them.

1. "If, after a full-term delivery or an abortion, there are no conception products in the uterus, and the patient has fever with exacerbations, chills, and a small and frequent pulse (120 to 140 or more), if careful observation should show that the infection comes from the uterus alone, that organ being enlarged and relaxed in its consistence, if there is no evidence of peritonitis, the parametria being free, if streptococci are found in the uterus, and especially if the blood shows the presence of pathogenic germs as in Prochownick's patients.

2. "If there are decomposition products in the uterus, as in the instances reported by Schultze, Sippel, Prochownick, and others, which cannot be removed satisfactorily *per vaginam*, if on doing a Cæsarean section the uterus is found septic—then an abdominal hysterectomy is indicated."

These indications exactly correspond to those I laid down in my papers, with the exception of the presence of streptococci in the uterus and in the blood of the patient, and a very important omission, which was to the effect that a hysterectomy was only to be entertained in the condition described in paragraph 1 after intra-uterine irrigations and stimulating treatment had failed.

My reasons for not determining as an indication for hysterectomy the presence of streptococci in the uterus were:

1. The presence of streptococci in the uterus does not necessarily argue that a given case of uterine sepsis will not be cured by less heroic measures. Bumm and others have found streptococci in abundance in the lochia and scrapings from the uterus in cases which ran a favorable course and were cured by curetting and irrigation.

2. Other bacteria than streptococci—*e. g.*, the *Staphylococcus pyogenes*, the *Bacillus coli communis*, the *Bacillus aerogenes capsulatus*, the bacteria of putrid decomposition—have each set up a sepsis so serious as to prove fatal.

Now, as to the presence of "pathogenic germs" in the blood. This, as an indication for hysterectomy, is at total variance with the context of the author's paper and his strenuous contention. He holds that acute bacteriæmia, which he tells us is "parasitic micro-organ-

isms invading the circulatory system from some primary seat of infection," is an absolute contra-indication to any operative procedure. He will probably reply that when he said the presence of pathogenic germs in the blood he meant that which occurs in chronic bacteriæmia (pyæmia). I should like to ask him now the same question that I did at the Obstetrical Society, to which he did not give a satisfactory reply: How many germs in the blood would he consider necessary to constitute the acute variety of bacteriæmia, and how many would be necessary to constitute the chronic variety? Further, if he meant chronic bacteriæmia (pyæmia), he has not stated the symptom *par excellence* of pyæmia, metastatic abscesses.

He states that the patients with septicæmia (acute bacteriæmia) generally succumb within five days after the disease begins. What term would he apply to that vastly larger proportion of cases in which they succumb after the fifth day, and which do not show any signs of pyæmia? Would he say they were cases of "sapræmia"?

In the matter of diffuse septic peritonitis, Dr. Boldt has made a complete change of front. He stated in his reply to me in the *Medical News*, April 16, 1898, p. 571: "I have operated upon a goodly number of women ill with acute puerperal septic peritonitis, hoping to save one or another, but so far in vain. If a major operation is performed, such patients die earlier, usually within thirty-six hours after the operation, the shock of the surgical procedure contributing to this." In his recent paper he states: "Abdominal section with drainage is indicated in diffuse septic peritonitis when there is no evidence of an exudate in the pelvis." It is to be regretted that the author did not state his reasons or give the data which influenced him in his change of mind on the question of diffuse septic peritonitis and hysterectomy for acute puerperal septic metritis or acute puerperal sepsis with the uterus as the sole source of infection.

HIRAM N. VINEBERG, M. D.

NEW YORK, March 6, 1901.

To the Editor of the *New York Medical Journal*:

SIR: I regret that Dr. Vineberg should make an article which was intended to act as a stimulus for further investigation in the subject of puerperal infection a basis for personal controversy. His questions in the letter to you have, if my recollection is correct, been answered in society discussions or personally. When Dr. Vineberg states that "the author had reference to my articles on the subject of puerperal sepsis which have appeared in various journals during the past three years," he is presuming on a statement that cannot be borne out by facts. To-day (March 6th) I took the trouble to read for the first time all of your correspondent's articles in the medical journals. In the headlines of his first article he describes the condition as a local infection, "Hysterectomy for Acute Puerperal Septic Metritis, etc.," but when one reads the article, it conveys the impression that he, in his opinion, had cured a patient ill with acute puerperal septicæmia. The second article clearly shows in the headlines that he maintains that he saved the life of the patient ill with puerperal septicæmia by removing an intensely inflamed tube and ovary. In his article he refers to a case published by Albert de Pourtales (*Archiv. f. Gynäk.*, vol. lvii, p. 36) which received a scientific microscopic examination, showing the invasion of the blood-vessels by septic micro-organisms; whereas his specimen received no such attention. This omission leaves us in doubt as to what

the true condition of his patient was. By personal observation, I can state that highly inflamed pelvic organs which produce intense constitutional symptoms resume their normal functions not infrequently without surgical intervention; so that his conclusions are only an assumption on his part. His patient may have got well, not because of her physician, but in spite of him.

In the third article the headlines also speak for themselves. I am unable to see any difference between the terms "acute puerperal sepsis" and "acute puerperal septicæmia." All the patients operated on and reported by the doctor had a local septic infection with intense constitutional symptoms. Whether the intervention to which he resorted was justifiable or not is a matter of personal opinion. Unfortunately for him, not one who saw the specimens and discussed them—one specimen excepted—shared his views. So far as the specimens themselves are concerned which were presented by him, they lose all scientific value, because in not a single instance was a microscopical or bacteriological examination made. They were merely macroscopical pathological specimens.

Complaint is made by him that I did not give him credit for laying down his indications for hysterectomy. I should gladly have done so, if anything therein had been original with him. As a matter of fact, long before the doctor reported his first case, not only I, but all who are engaged in this line of work, had been for a number of years led to perform such operations on similar indications.

The doctor asks me "How many germs in the blood would be considered necessary to constitute the acute variety of bacteriæmia, and how many would be necessary to constitute the chronic variety?" I regret our inability to distinguish between acute and chronic bacteriæmia by the number of micro-organisms found in the blood. The clinical picture usually does this. I thought that it was evident from my article that, so far as the results of bacteriological examinations were concerned, the acute bacteriæmia could not be distinguished from the chronic bacteriæmia. This distinction may be made only from the course of the disease. Again, if he has read my article, he must know that metastatic abscesses were included by me under the picture of chronic bacteriæmia (pyæmia).

Once more Dr. Vineberg asks: "What term would he apply to that vastly larger proportion of cases in which they succumb after the fifth day, and which do not show any signs of pyæmia? Would he say they were cases of 'sapræmia?'" If the thrombotic blood-vessels of patients who die as the result of septic infection so long after abortion or full-term delivery are examined, it will be found that they contain numerous sepsis-producing micro-organisms. This condition is frequently spoken of as septicopyæmia, a term invented to cover this mixed condition.

I have in no way changed my mind or opinion, although he insists that I have done so, with regard to our inability to cure patients ill with acute puerperal septicæmia, or, as he terms it, "acute puerperal sepsis," by performing hysterectomy.

As for my "change of front," I said that abdominal section with drainage was indicated in diffuse septic peritonitis, and this opinion is now generally accepted by the profession at large. To illustrate my conception of diffuse septic peritonitis, see the *Medical Record* for February 2, 1901. The case mentioned here, however, can be called a chronic form of diffuse septic peritonitis;

whereas there are other cases of acute septic peritonitis, if not dependent upon puerperal infection, but upon rupture of an ulcer or an appendicular abscess, etc., which may be cured by similar intervention. I, too, have been able to save several such patients with that treatment. Acute septic puerperal peritonitis is, however, a different condition so far as prognosis is concerned, I placing it on the same basis as septicæmia (acute bacteriæmia).

How much practical benefit may result from careful bacteriological blood examinations such as I, in line with others, am carrying out in all patients ill with septic infection who have serious constitutional symptoms, remains to be seen. Another object of my article, in addition to the intended stimulus to work on a more scientific basis on the question of puerperal infection, was to clear up just such confusion of terms and definitions as seemingly exists in the minds of some members of the profession, as is evident when one reads Dr. Vineberg's articles. It is useless for me to argue with the doctor so long as he apparently does not comprehend what the term septicæmia (for which I have substituted the term acute bacteriæmia) means.

H. J. BOLDT, M. D.

Book Notices.

Sanity of Mind: A Study of its Conditions, and of the Means to its Development and Preservation. By DAVID F. LINCOLN, M. D. Pp. vi-177. New York and London: G. P. Putnam's Sons, 1900.

IN this little work the author sets forth, in a generally comprehensible, if not in a popular, way much about insanity which is of public interest. Beginning with general remarks, the second and third chapters deal with the nature of mental derangement in accordance with the latest classifications, and with degeneracy. The subsequent chapters are devoted to education, to self-education, and to our social and civic duties in regard to insanity.

The author is sound in his propositions, emphasizing throughout that in the proper education and training of neuropathic children, in the early detection and treatment of the insane diathesis, and in the quick recognition of a beginning mental disorder, together with a more general social recognition of such conditions, lies our greatest hope of diminishing the number of the insane. Were books of this character more popular we might hope for more satisfactory legislation in regard to the early and preventive treatment of insanity.

Manual of the Diseases of the Eye. For Students and General Practitioners. With 243 Original Illustrations, including 12 Colored Plates. By CHARLES H. MAY, M. D., Chief of Clinic and Instructor in Ophthalmology, Eye Department, College of Physicians and Surgeons, Medical Department, Columbia University, New York. Pp. xiii-406. New York: William Wood & Company, 1900.

THIS excellent little book fulfils its purpose as stated in the preface, namely, to say enough and not too much, especially for the student. It is doubtful, however, whether it will be of as much value to the general practitioner.

It is extraordinary that so much that is valuable—all, in fact, that is essential to those for whom it is in-

tended—should be compressed into such a small compass, and it is but natural that much that is interesting and that would add to the literary value of the book has been sacrificed. It is far superior to the usual book of the compend type, and will rank in popularity, we doubt not, with Swanzy and Nettleship.

The illustrations, most of which are original, are admirably clear and simple, especially those in colors, and the work of the publishers is above criticism.

Original Contributions Concerning the Glandular Structures Appertaining to the Human Eye and its Appendages. By ADOLF ALT, M. D., Professor of Ophthalmology in Beaumont Hospital Medical College, St. Louis. Pp. 23. St. Louis: *American Journal of Ophthalmology*, 1900.

THE seventy-one original illustrations which form the basis of this book are of unequal value. They certainly show the industry of the author, though they may not add materially to the sum of medical knowledge.

It is a question whether it is not better to combine several pictures of the same object into a composite, diagrammatic result if this could be done without bias, rather than to repeat a number of unimportant variations which show little more than the amount of work done.

The subject is treated with independence, credit being given to A. Terson and to E. Bock for their work in the same direction.

The comment on page 16, regarding the apparent misstatement of Fuchs concerning Krause's glands, evidently depends on the translation.

The Practice of Medicine. A Text-book for Practitioners and Students, with Special Reference to Diagnosis and Treatment. By JAMES TYSON, M. D., Professor of Medicine in the University of Pennsylvania and Physician to the Hospital of the University, etc. Second Edition, thoroughly Revised and in Parts Rewritten. With 127 Illustrations, including Colored Plates. Pp. vii-17 to 1222. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$5.50.]

IN the second edition of this able work a considerable revision appears, more particularly in the portions of the book dealing with the diseases of the blood and of the nervous system, as well as with the infectious diseases. With these revisions and additions the work may properly be said to represent what is most modern in its field. The favorable opinion entertained generally for the first edition of the book is not likely to suffer diminution in the case of the second; indeed, it is one of the best of the modern works upon the practice of medicine.

On Some Cirrhoses of the Liver. Being the Lumleian Lectures for the Year 1900, delivered before the Royal College of Physicians, London. By WALTER BUTLER CHEADLE, M. A., M. D. Cantab., Senior Physician and Lecturer on Clinical Medicine, St. Mary's Hospital, London, etc. With Illustrations. Pp. 109. London: Smith, Elder & Company, 1900.

THESE lectures, being the Lumleian lectures for 1900, have before appeared in print. They cover well the field of cirrhosis, several interesting phases of the pathology and treatment of the disease being especially dwelt upon in an absorbing manner; thus, the occurrence of jaundice in cirrhosis, the treatment of syphilitic cir-

rhosis with mercury and the iodides, the phases of paracentesis, etc. The little volume is well illustrated and is a worthy contribution to its subject.

A Manual of Medicine. Edited by W. H. ALLCHIN, M. D. Lond., F. R. C. P., F. R. S. Ed., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital, etc. Volume II. General Diseases—Continued. Diseases Caused by Parasites; Diseases Determined by Poisons Introduced into the Body; Primary Perversions of General Nutrition; Diseases of the Blood. Pp. vi-380. New York and London: The Macmillan Company, 1901. [Price, \$2.00.]

THE second volume of this manual continues the discussion of general diseases and, to particularize, presents the diseases caused by parasites and those occurring from the introduction of poisons, the disorders resulting from perversions of general nutrition, and the diseases of the blood. The text is of most excellent quality, as must needs be when one considers the list of contributors, and of an exhaustiveness sufficiently complete; in fact, it is one of the strong features of this work that it gives one all that is essential upon the various subjects presented, without that microscopical detail that would seem unavoidable in more pretentious works. The reasonable and readable sufficiency of the book we have spoken of before this. No detailed comment need be made in the case of this volume, we think; the various contributions are able and harmonious, but the one upon gout has given us particular satisfaction as being a very simple and straightforward handling of the subject.

An American Text-book of Physiology. By HENRY P. BOWDITCH, M. D.; JOHN G. CURTIS, M. D.; HENRY H. DONALDSON, Ph. D.; W. H. HOWELL, Ph. D., M. D.; FREDERIC S. LEE, Ph. D.; WARREN P. LOMBARD, M. D.; GRAHAM LUSK, Ph. D., F. R. S. (Edin.); W. T. PORTER, M. D.; EDWARD T. REICHERT, M. D., and HENRY SEWALL, Ph. D., M. D. Edited by WILLIAM H. HOWELL, Ph. D., M. D., Professor of Physiology in the Johns Hopkins University, Baltimore. Second Edition, Revised. Pp. 3 to 598. Philadelphia: W. B. Saunders & Company, 1900. [Price, \$3.]

THE most striking change noticeable in the second edition of this work, as compared with the first, is its appearance in two good-sized and well-shaped volumes. This change will doubtless conduce to the popularity of the work; it certainly adds to its usefulness. A certain amount of revision is noticeable in the later edition, more especially in the portions that deal with the central nervous system, but essentially the text is unaltered. In our review of the first edition we spoke in praise of its many excellences; these remarks remain true of the revision, and its two-volume form, as we have just said, is an added advantage.

BOOKS, ETC., RECEIVED.

A System of Practical Therapeutics. Edited by Hobart Amory Hare, M. D., Professor of Therapeutics and *Materia Medica* in the Jefferson Medical College of Physicians, etc. Second Edition, Revised and largely Rewritten. Volume II. Fevers—Diseases of the Respiratory and Circulatory Systems—Diseases of the Digestive System and Kidneys—Nervous Diseases and Diseases of the Skin. With Illustrations. Pp. 3 to 926. Philadelphia and New York: Lea Brothers & Company, 1901.

A Medico-legal Manual. By William W. Keysor, Lecturer on Medical Jurisprudence in the Omaha Medical College, etc. Pp. 316. Omaha: Burkley Printing Company, 1901.

The Syphilis of Children in Everyday Practice. By George Carpenter, M. D., Lond., Physician to the Evelina Hospital for Sick Children, London. Pp. 9 to 112. New York: William Wood & Company, 1901.

An Atlas of the Bacteria Pathogenic in Man, with Descriptions of their Morphology and Modes of Microscopic Examination. By Samuel G. Shattock, F. R. C. S., Joint Lecturer on Pathology and Bacteriology, St. Thomas's Medical School, London, etc. With an Introductory Chapter on Bacteriology: Its Practical Value to the General Practitioner. By W. Wayne Babcock, M. D., Pathologist to the Kensington Hospital for Women, etc. Sixteen Full-page Colored Plates. Pp. 7 to 82. New York: E. B. Treat & Company, 1901.

The Use of the Röntgen Ray by the Medical Department of the United States Army in the War with Spain (1898). Prepared, under the Direction of Surgeon-General George M. Sternberg, United States Army, by W. C. Borden, Captain and Assistant Surgeon, United States Army. Pp. 5 to 98. Washington: Government Printing Office, 1900.

La Surdi-mutité. Étude médicale. Par Etienne Saint-Hilaire, Médecin auriste de l'Institut de Sourds-muets du Département de la Seine, etc. Pp. 300. Paris: G. Maloine, 1900.

Bibliographie générale des travaux parus sur lait et sur l'allaitement jusqu'en 1899. Par le Dr. Henri de Rothschild, Lauréat de la Faculté de Médecine. Avec une préface de M. E. Duclaux, Directeur de l'Institut Pasteur. Pp. xii-584. Paris: Octave Doin, 1901.

Report of the Commissioner of Education for the Year 1898-1899. Volume II.

Thirty-third Annual Report of the Board of Water Commissioners of the City of Middletown, N. Y. For the Year ending January 31, 1900.

Tenth Annual Report of the State Board of Medical Examiners of New Jersey. 1900.

Annual Report of the Department of Health of the City of Niagara Falls, N. Y. For the Year 1900.

Transactions of the Luzerne County, Pa., Medical Society. For the Year ending December 31, 1900.

New Inventions, etc.

AN APPARATUS FOR THE THERMAL TREATMENT OF THE EXTERNAL AUDITORY CANAL.*

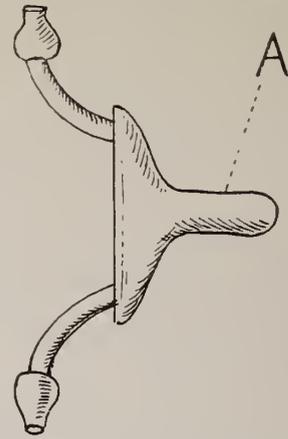

By EMIL AMBERG, M. D.,

DETROIT.

WE know that ear patients, under certain circumstances, are greatly benefited by applications to the external ear. I submit to the profession an apparatus by the aid of which such treatment can be carried out in the external auditory canal. It is shown in the accompanying cut. The apparatus, made of metal, is hollow, closed at the end, and has two tubes, one for the inflow and one for the outflow of the fluid. Part A is flattened

*Demonstrated before the Detroit Medical Society, January 30, 1901.

and should not be longer than one centimetre. The instrument is to be used in the same manner as Leiter's

coil. I have had the apparatus constructed on general principles, and I hope to be able to report on its merits as soon as an opportunity presents itself.

Miscellany.

Tendon Transplantation for Deformity of the Hand.

—At a meeting of the New York Neurological Society held on February 5th, Dr. W. R. Townsend presented a patient who had been exhibited to the society about a year before. The case was one of infantile cerebral palsy. Instruments had been used at the time of the patient's birth, but apparently no damage had been done to the exterior of the skull. He had never been able to use the right hand, and it was a typical "claw-hand" when the boy came under observation, at the age of fifteen years. On December 21, 1899, an incision was made over the wrist, exposing the tendons. The flexor carpi radialis, the flexor carpi ulnaris, and the palmaris longus were divided just above the annular ligament. The hand was then turned over and an incision made on the dorsum of the wrist, exposing the extensor communis digitorum. A dissection having been made through the interosseous space, the extensor tendon was pushed through and, being too long, was doubled upon itself. It was then attached to the tendons previously mentioned. The union of the tendons had been satisfactory and permanent. The tendons had not shown any tendency to unite to the surrounding tissues. The boy was now able to write fairly well, whereas formerly he could not even grasp a pen.

Dr. B. Sachs said that it was certainly the best procedure that had been suggested for these cases of contracture, whether of spinal or of cerebral origin. The problem was to split the tendons of the overacting muscles and unite them to the tendons of the underacting muscles, and so restore the equilibrium of power. It had been found prudent not to allow the patient to exercise much or to use electricity until the tendinous union had become very firm. It was unfortunate that this boy was not able to extend his fingers, yet he had good power of extension of the wrist. In spite of the tendon transplantation, the boy experienced no difficulty in producing flexion when he desired to do so.

Paralysis of the Spinal Accessory Nerve.—At the same meeting Dr. Pierce Bailey read a paper in which he said that the chief interest of this nerve was surgical.

Within the past year two instances had come to his notice of accidental section of the nerve. In most cases the paralysis which resulted from section was not particularly disabling, but such had not been the case in the instances referred to. When the sternomastoid was completely paralyzed, the freedom of movement of the head was interfered with, but not totally abolished. In the two cases referred to, the disability had been unusually great, and had led him to study the nerve more carefully. It was now regarded as a spinal nerve, pure and simple. The spinal portion of the nerve, represented by the external branch, sprang from the upper five segments of the cord. Paralysis of the nerve presented a varying symptomatology, according to the site of the lesion. An injury outside of the skull, to cause symptoms referable to both branches, must be situated directly at the base of the skull. The extracranial lesions of the spinal accessory were confined to the external branch, and were nearly always traumatic. Inflammation in this nerve was rare. A case was cited to illustrate the possible traumatic origin of spinal accessory palsy by injury with a blunt instrument. In two other cases reported the paralysis had been directly the result of an operation. In the second case the resulting incapacity had been so great that the right arm had been rendered practically useless for any heavy work. Neurorrhaphy had been performed about six weeks after the operation at which the nerve had been injured, and the ends of the divided nerve had been found separated over one inch. The improvement in motor power had been slow. A reference to the literature showed conflicting views regarding the nerve supply. Dr. Bailey said that the spinal centre between the first and fifth cervical segments of the cord was fixed and constant, but occasionally all the axones passed to the muscle by the spinal accessory. Under these circumstances the motor impulses reached the trapezius through the spinal accessory, and, hence, section of it meant total palsy.

Dr. W. M. Leszynsky said that two months before he had seen a patient who had been operated upon for torticollis. Over an inch of the spinal accessory nerve had been removed on the left side without relief, and the function of the muscle had remained perfectly normal. He had seen over an inch of the other spinal accessory nerve removed subsequently, yet the muscle had not been affected at all; hence he had held that it was useless in these cases of spasm to operate upon the spinal accessory nerve.

Dr. J. Arthur Booth said that he had had a case of spasmodic torticollis treated by section of the spinal accessory nerve. A little more than an inch had been excised, and the sternomastoid and part of the trapezius had been paralyzed as a result.

Epicondylar Fracture of the Elbow.—At a meeting of the Section in Orthopædic Surgery of the New York Academy of Medicine, held on January 18th, Dr. Homer Gibney presented a small boy who had sustained a fracture of the elbow three months previously. The fracture was above the condyle. When the patient presented himself at the hospital the elbow was fixed at an angle of 105°, with but little movement. The joint was cut down upon by Dr. V. P. Gibney and the detached fragment sutured into place. Dr. V. P. Gibney said that the epicondyle and nearly the entire condyle had been displaced, interfering with motion. He had cut down upon the joint and separated it with an osteotome, cleaned off the site of the fragment, and pushed it down, suturing with kangaroo tendon; he had then put the arm

in a straight position, left it for four or five weeks, and then allowed active motion. Passive motion was not employed. Dr. T. Halsted Meyers commented upon the excellent result and remarked that children were often allowed to go on with fracture of the elbow united in poor position, in the belief that they would outgrow the disability in a great degree, which was true, but it was better to correct the deformity entirely, even resorting to an open operation when necessary. He called attention to Dr. Lloyd's excellent reports.

Statistics of Grippe in New York State.—The New York State Board of Health has issued a report on grippe which shows that the disease made its appearance in 1889. Every year since, in the winter season, it has recurred, the annual epidemic having various characteristics. The number of deaths which occurred each year from the disease is as follows: 1890, 5,000; 1891, 8,000; 1892, 8,000; 1893, 6,000; 1894, 3,000; 1895, 5,000; 1896, 2,750; 1897, 3,000; 1898, 2,500; 1899, 7,000, and 1900, 11,500. The report says: "Of the distribution of the disease, it has not been found to be one of either the city or the country. It is a disease of the colder months. It has varied greatly in severity in different years; it seems likewise to have varied greatly in virulence in different localities and shown varying types. It likewise varies in rapidity of spread. It is evidently communicable from the individual directly and conveyable in infected clothing. Like all zymotic diseases, susceptibility to it varies; unlike some, immunity does not follow a previous attack. The State is now in the course of the twelfth recurrence of grippe. Affecting the mortality of December by about 500, it has increased the number of deaths in January by probably 3,000, and was still in progress during February."

The Vital Statistics of Havana for January, which have been issued by Major Gorgas, chief sanitary officer, show that the number of deaths, 476, is the smallest that has occurred in any January in Havana in the last twelve years, the next lowest being that of January, 1890, 486 deaths; the highest being that of January, 1897, with 1,556 deaths. The death rate for this month, 22.75, is considerably less than the lowest for the past twelve years, 1894 being the next lowest with a rate of 27.36. In 1899, as shown by the report, the rate for this month was 63.84; in 1900, 23.90. The rate for last year was 24.40. Yellow fever has decreased from 62 to 24, and the deaths from this cause from 20 to 7. The number of deaths is kept up by the increase among the deaths from tuberculosis, which about balances the decrease in deaths from fevers.

The Antivaccination Movement has taken its most definite form apparently in Massachusetts, where much oratory and enthusiasm came to the surface during the hearing before the committee on public health of the Massachusetts legislature on a bill doing away with compulsory vaccination for school children. Dr. James D. Bell, of Boston; Dr. Montague R. Levenson, of Brooklyn; Dr. W. B. Sanders, William Lloyd Garrison, and Mr. Foster, a member of the House of Representatives, all appeared in favor of the bill. Dr. Levenson stated that he had for the time being abandoned his practice so as to devote his time to furthering the antivaccination movement.—A bill has been introduced in the Pennsylvania legislature to repeal that section of the law which makes the production of a certificate of vaccina-

tion necessary before a pupil is admitted to the public schools. The bill is not expected to pass, having been very actively opposed by the board of health and by the medical societies generally.—An antivaccination society met at a private residence in Cleveland, O., recently, and Dr. J. P. MacLean criticised the local health board for its failure to prevent the spread of small-pox.

Health of English Towns.—The vital statistics of thirty-three large English towns, including London, for the year 1900, as summarized in the *British Medical Journal*, show the annual birth rate per thousand of population to be 29.24, or 1.8 per 1,000 below the rate for the previous ten years, while the death rate is 19.5 per 1,000, or 0.8 per 1,000 lower than the death rate of the preceding decade. In London the birth rate was 28.6 and the death rate 18.8 per 1,000, as against a rate in the provincial towns of 31.2 for births and of 20.2 per 1,000 for deaths. Of these deaths, 2.50 per 1,000 were from zymotic diseases.

A Hospital Tag for Discharged Patients.—The Samaritan Hospital of Chicago has adopted a novel system of identifying former patients. It consists in giving to each patient, on leaving the institution, a metal tag to be constantly worn, bearing the following inscription: "In case of accident, telephone this number — to Samaritan Hospital, Chicago. They will notify my friends and give you instructions." A record is kept of each case by number, and in this way appropriate remedies can be promptly resorted to in case of sudden illness.

The Losses from Disease in South Africa were the subject of a parliamentary inquiry in the British Parliament recently. Statistics show that up to the end of last year more than 7,500 had died of disease and more than 30,000 had been sent home as invalids. The Government stated that the introduction of military titles for medical officers had not had altogether the best effect. The Government also stated that the leaders of the medical profession would be consulted, with a view to reforming and making more effective the army medical service. In the course of the inquiry the Secretary of State for War said that during October there were 568 cases of typhoid, with 98 deaths; in November 1,013 cases, with 207 deaths, and in December 1,065 cases, with 286 deaths. The total number of cases from the beginning of the war to December, 1900, was 19,101, and of deaths 4,233. The number of officers and men invalided for enteric fever who had arrived from England from the beginning of the war to December, 1900, was 10,975.

The Amateur Nurse.—She was young, pretty, and distinguished, and she had volunteered as a nurse in South Africa; so, when she reported for duty, she asked the medical officer what she ought to do. "You are supposed to know your duties when you come here," curtly replied the harassed doctor, who had answered the same question many times before. "Do anything you find that needs doing."

The amateur nurse looked wistfully around, then marched to the cot of a handsome Highlander and asked him: "Will you let me wash your face?" The wounded soldier turned wearily to her and said: "Yes, ma'am, but please hurry up. It has been washed six times since breakfast, and I've already promised to let two other ladies wash me, but perhaps I can manage to get a nap before tea."

And still a slanderous doctor publicly inveighed against the two plagues of the South African campaign, flies and women!

The Diagnostic Value of the Reactions of Degeneration in Cases of Progressive Amyotrophy.—M. Jules Abadie (*Nouveau Montpellier médical*, October 21st and 28th), as the result of a careful clinical study of this subject, arrives at the conclusion that the facts are calculated to render one somewhat skeptical in regard to the diagnostic value of the reaction of degeneration. So far back as 1893, Guinon wrote that "the presence of the reaction of degeneration, or rather the inversion of the formula of electrization of certain muscles, is not conclusive in the establishment of a diagnosis." This view has lost none of its importance, but rather gains daily support from new facts. 1. Anatomico-pathological study shows, in the two kinds of amyotrophy, similar lesions (without doubt due to trophic troubles). 2. The reaction of degeneration tends to disappear as a distinguishing characteristic of myopathic and myelopathic atrophies, as well from clinical demonstrations as from the data of physio-pathology. 3. There is, then, no reason why the two kinds of amyotrophy should not be more and more recognized as acknowledging a central origin, and an absolutely general purport may be given to Professor Grasset's proposition: "Muscular atrophy is the syndrome of the inferior central motor neurone."

Operations on the Intestine.—Dr. C. S. Hamilton (*Columbus Medical Journal*, September) reports four operations upon the intestines in connection with strangulated hernia, and concludes that the essentials for a successful suture of the intestinal tract may be enumerated as follows:

1. Free access to the field of operation by incision suitably located and of sufficient length. In dealing with strangulated hernia this frequently implies incision into the parietes beyond the anatomical limits of the hernia itself.
2. Rigid asepsis and special provision by properly arranged towels and compresses for catching intestinal contents, which necessarily escape to a greater or less extent.
3. Temporary compression of the intestine on either side of the proposed operation by clamps, gauze strips tied around the bowel, or the fingers of the assistant, to prevent the escape of fæces.
4. In the case of excision for any condition, division of the intestine in a healthy area wide of the disease, so that the tissue changes upon which union depends may progress normally.
5. Careful cleansing of the cut ends of the bowel and the V-shaped excision of the mesentery with the necessary hæmorrhage. The vascular relation of the mesentery to the bowel is to be borne in mind at this stage.
6. Union of the mesentery, and of the intestine by suture alone or by suture associated with some mechanical device.

Hamilton believes that the majority of operators prefer simple sutures, except when there is a demand for speed. When this is the case the Murphy button is one of the most satisfactory devices for end-to-end union. The value of Senn's decalcified bone plates in lateral anastomosis is well known.

In end-to-end union the first line of suture includes the mucosa, the operator using, according to his individual preference, catgut or fine silk, interrupted or continuous; the second row consists of Lembert sutures penetrating the peritoneal, muscular and tough submucous coats. The adaptation of the mesenteric borders of the intestines demands the greatest care and accuracy, as it is here that leakage occurs if anywhere.

Original Communications.

SOME RETROSPECTS AND PROSPECTS IN GENITO-URINARY SURGERY.*

By REGINALD HARRISON, F. R. C. S. Eng.,
LONDON, ENGLAND.

THOUGH my friend, Dr. Samuel Alexander, whose place at this clinic I occupy to-day, endorsed by my still older colleague and host, Dr. Frederic S. Dennis, gave me, on my arrival in New York a few days ago, but little chance of escape into Florida, I feel that an apology is due from me to you for addressing you on a subject relating to the practice of surgery which will not present any material feature of originality or novelty. I propose to consider Some Retrospects and Prospects. The old century is past and gone, and I am reminded that it has left behind it important landmarks of progress which, though at the present moment they may perhaps be regarded somewhat in the light of ancient history, are full of suggestion as to the directions research is likely to take with advantage to the cause of science in the new epoch that has opened.

Thus may the past furnish view-points wherefrom to anticipate the future, and so tend to free me from feeling that I may not aimlessly have occupied the time of so distinguished a gathering of my American brethren who have so warmly again welcomed me amongst them.

It would amount to false modesty on my part if, in the face of my various contributions to the surgery of the urinary organs and its literature, both at home and in America, I were to hesitate to address you on some matters relating to this interesting and far-reaching subject. In pursuance, therefore, of my idea of attempting to show how one recognized advance may be regarded as merely an instalment in the direct line of progress or discovery, I will take up the several points I wish to illustrate in the order in which they have casually presented themselves to me and have occupied my attention.

In addressing an audience of physicians and surgeons in the United States, I need hardly say that amongst the most prominent advances in surgery that distinguished the last century was the development of the operation for vesical stone by Professor Bigelow, of Boston, and the perfecting of the process now known under the name of litholapaxy, wherein the crushing of the stone with the lithotrite was immediately followed by the rapid evacuation of the fragments so triturated and prepared.

On the occasion of my first visit to America, in 1878, it was my good fortune and privilege to see some of Bigelow's earliest operations, as recorded in his work, and to hear from the lips of this distinguished surgeon

the expectations he hoped to realize. The latter have been accomplished, the operation has generally been accepted, and the mortality and suffering connected with the removal of stone from the bladder have been greatly diminished. Shortly after this visit it fell to my lot to demonstrate for the first time in my own country the instruments and processes employed by Bigelow, and in a very short time to witness the supplanting of old methods by what at that time was new and original. It is a point of interest to notice, as indicating the completeness of the mechanism proposed and adopted at the time referred to, that the apparatus used now is practically the same as that with which Bigelow himself worked, a set of instruments being now in my possession as he presented them to me. It is rare to find the details connected with a complex discovery in its early stages so complete in all respects as this appears to have been.

It is impossible not to recognize at this stage of my remarks that Bigelow's proposal to revolutionize the operation for the treatment of vesical stone in the way I have described, particularly in reference to the character of the instruments employed in his operation, was doubtless influenced by another discovery which preceded it. I can remember Bigelow mentioning this subject on more than one occasion, thus again indicating how one advance is often dependent upon another. I refer to the late Dr. Otis's investigations as to the size of the male urethra, and the greater degree of distention, as compared with the former views, it was capable of undergoing without detriment to the normal canal and with much permanent advantage to the strictured one. This was an important precedent to Bigelow's proposal, which followed in its wake.

These are, I admit, matters which I would now speak of, with all respect, as of ancient history. But Bigelow's influence over others in regard to this operation did not cease with him. In the course of time, and as experience increased, it became clear that, though his operation was both safe and successful, it was open to be followed by recurrences which tended to limit somewhat its application, and to the substitution of less desirable methods.

The prominence given to the latter consideration by the analysis of results has directed attention to the importance of applying knowledge we possess, but have not hitherto sufficiently used, as to the probable mode in which urinary stone and concretions are formed, and the influence that the enlarged prostate exercises on the trapping, the formation, and recurrence of these bodies. Hence I have alleged for Bigelow's work, in reference to the subject of stone alone, not only that he has provided us with the best and most scientific method of removing stone from the bladder, as demonstrated by over twenty years' experience of it, but that the application of it has actually been the means of demonstrating that, apart from the mere mechanism of

*An address delivered at the Medical School of Cornell University, March 13, 1901.

these operations, there are underlying considerations connected with them to which importance has not hitherto been sufficiently attached.

Time will not permit me to go over that ground connected with this aspect of Bigelow's work which I have recently occupied and publicly discussed. Since the time when, some years ago, the American Surgical Association was good enough to confer upon me the great distinction of their honorary fellowship, I have not omitted, whenever I happened to contribute anything to the medical press or to our societies, which in my humble judgment seemed worth repeating and reprinting, to forward a copy of the reprint to my colleagues in America belonging to this association as some trifling acknowledgment of their kindness to me.

The Probable Mode of Formation of Urinary Stone in Relation to Rainey's Views on Molecular Coalescence, and the Bearing of Prostatic Enlargement and its Complications upon Stone Recurrence, was the title of the most recent reprint I have had the honor of submitting to the fellows of the American association in the spirit I have just referred to. It would be unnecessary to further refer to it. I may, however, briefly remind some present here to-day who may be unacquainted with Rainey's work in reference to the subject of stone, that he demonstrated at St. Thomas's Hospital in London, so far back as 1857, a mode of making calculi artificially by what he described as "molecular coalescence." The more recent works and demonstrations of the late Dr. Vandyke Carter and Dr. W. M. Ord have confirmed and extended these views. From them we may conclude, as I have already stated: (1) that for the production of calculi artificially by molecular coalescence, *precision* in regard to all details connected with it is required; (2) that success in moderation is dependent upon the sequence or concurrence of several factors or fixed conditions; and (3) that molecular coalescence, as first described and taught by Rainey, explains the formation of calculi in the human urinary apparatus. By the kindness of my colleague, Dr. Dennis, I have had the opportunity of seeing within the last few days the splendid laboratories for research which this, the new building connected with the University of Cornell, contains. I have never seen anything to equal them, much less to surpass them, in their construction and equipment. I do not know any subject which is likely to afford greater fascination or intellectual profit to the graduates and others than repeating Rainey's experiments relative to the formation of stone, with a view to their further development in the cause of both prevention and cure, under the very favorable conditions which exist in this building, for I can only speak of it as a palace devoted to the highest and most humane kind of research.

It is somewhat remarkable, judging from their omission, as a rule, from all surgical text-books, including special treatises on the subject, that hitherto Rain-

ey's views have received so little prominence and attention at the hands of practical physicians and surgeons. This is to be regretted, as a knowledge as to the construction of these concretions is a necessary preliminary to their treatment by operation or otherwise. I have endeavored in the treatise referred to to afford evidence and reason for this. Had Bigelow, by inference, done no more than give prominence to defects inseparably connected, to some extent, with all operations for the treatment of stone, his memory would still have deserved our consideration and respect.

Without any special reference to stone recurrences or Bigelow's operation for its relief, in 1893 our colleague, Dr. William White, of Philadelphia, propounded the suggestion, by rational deduction, that by the removal of one or both of the testicles the hypertrophied prostate might be arrested in its growth, or even be reduced in size. This has been successfully demonstrated, and upon this other practices, such as the obliteration of the vasa deferentia and other constituent parts of the spermatic cord, have been founded, and followed by varying degrees of success and of failure. Out of this a considerable controversy has arisen, which still goes on. There can be no doubt whatever that a certain amount of success has thus been attained by one or other of these means, though the results obtained have been so variable as to give rise to some perplexity, which I think it should be our business to endeavor to remove. All this, as I have said before, is ancient history, so far as the present century is concerned. But what about the future? Are all the records which divided opinions have called forth during the last seven or eight years not worth the paper upon which they are written, or are we to go back and take up the position of matters before this class of operation was launched upon the expectant world of urinary surgery? I think not. Cautiously feeling our way, as a pilot does in foggy weather when in the neighborhood of obstructions, some of which are merely sand which delay, whilst others are rocks which would sink, we are beginning to recognize that the term "enlarged prostate," by which I mean the hypertrophied prostate, is, surgically speaking, a generalization which, in relation to the application of treatment, is liable to mislead. What should we think in the present day of a surgeon who proposed to discuss for this purpose enlargements of the breast or injuries to the hip without further definition? In the near future, judging from observations which are steadily going on, the surgical treatment of the prostate, when it has reached that stage or mechanism as to seriously obstruct the function of the bladder and to be unmanageable by the catheter, will largely turn, as in the almost analogous case of the tonsils and the throat, upon the evidence that is mainly afforded by an ocular inspection of the parts. For such purposes the development of electric cystoscopy, with the view of determining the precise nature, as well as

the shape and relations, of the obstruction it is proposed to remedy by surgical means, has already proved of much advantage.

I would stop for a moment to illustrate this point in the following way as bearing upon others already touched.

In a case of rapidly recurring stone in the bladder of a man under sixty years of age, it was found by cystoscopic examination, before repeating Bigelow's operation of litholapaxy for the third time within two years in an otherwise healthy man, that a pedunculated or tongue-like process of prostatic tissue, but slightly detectible by rectal examination, had practically converted the lower and posterior segment of the bladder into a box with a movable lid of prostate, which, by confining a certain proportion of the urine, brought about its decomposition and rendered it liable to produce that kind of phosphatic stone when it was submitted to such conditions.

On this being accurately determined in the manner described, it was recognized that the calculus was only to be regarded as a natural consequence arising out of this condition of the parts; as a fact, it would have been wrong if a stone had not formed under such inviting circumstances as presented. I therefore practised the median perineal *boutonnière* operation and twisted off the narrow-necked growth connected with the central flaps of the prostate. Under cover of it were two phosphatic stones about as large as common filberts. A drainage-tube was temporarily introduced, and, when I left home a fortnight after the operation, the patient was progressing favorably. This is a fair illustration of what the cystoscope may do in cases of this kind. The operations for stone were in no sense at fault.

In a recent paper, which I think I have also submitted to the fellows of your surgical association, I have endeavored to show that there are at least three varieties of prostatic hypertrophic obstruction, which, it is obvious, would not be likely to admit of a uniform method of operative treatment. There are other varieties in shape, but these three may be taken as typical of what in practice are most frequently met with as obstructing the function of the bladder. The more general hypertrophic growth is one usually associated with more or less congestion and engorgement, and presents the variety in which vasectomy, castration, and possibly Bottini's operation, have furnished the larger majority of good results. The pendulous prostatic outgrowth is not suited to any one of these proceedings I have just mentioned, but is best dealt with in the manner I have illustrated by the narration of a case; while the obstruction which is represented by the presence of interstitial adenomata analogous with what occurs in connection with the female breast and the tonsils, has been most successfully dealt with by enucleation through the suprapubic incision. By distinguishing these various conditions of prostatic hypertrophy, there seems every

prospect of obtaining more uniform and better results from this class of operations.

Let me now turn, in continuation of my review, to the pathology of the kidney in reference to what seems to promise to be an addition to its surgery.

The surgery of this organ is a creation and feature of the nineteenth century. We deal with it surgically in a variety of ways, with good success, for diseases and conditions which, if left to take their natural course, would speedily prove fatal. These I need not enumerate or further detail, as they are matters of more or less ancient history. But what about the future? As president of the Medical Society of London, in 1896, at the suggestion of the late Sir William Roberts, my presidential address was devoted to the subject of renal tension in relation more particularly to the continued presence in the urine of albumin as a prominent feature of disease.

The basis of these remarks arose partly out of the observation of the living kidney as seen in connection with its exploration for doubtful states of disease, such as stone, abscess, and pain; and partly from cases of more or less chronic albuminuria, where, after the search for likely temporary causes for this, the albumin had subsequently, entirely and, so far as I know, after considerable periods of observation, permanently disappeared from the urine.

Exploratory observations of the kidney, in addition to the examination of post-mortem specimens removed after periods of intense renal congestion, such as occur in connection with scarlet fever and some acute forms of nephritis, have led me to think that we underrate, or do not correctly estimate, the damage that may be done to the secreting portion of the kidney in this way. With the exception of the eye, there is probably no more delicate structure in the human body than that which is engaged in excreting so complex a fluid as the urine. Nor, having regard to the way in which this structure is packed away in, so to speak, compartments composed of slowly yielding fibrous tissue, and the whole invested in a capsule of the same nature, is there any other organ more likely to suffer from the effects of tension, however this may be produced? That the degree of tension in the kidneys is, at times, considerable and unusual, is often apparent on their exploration. Not only are they found deeply colored, tense, and resisting to the touch, but I have frequently seen, on puncturing the capsule for the purpose of exploring, blood spurt out in jets, as if projected under considerable contractile pressure and eager to escape.

It seems to me that, as with the eye, the testicle, and other structures of the body that will occur more particularly to the surgeon, such pressure, when long continued, may be capable of causing considerable damage, which is not lessened by the subsequent processes of repair that are rendered necessary; thus may easily be commenced a series of changes, hypertrophic and other-

wise, which it is not unreasonable to suppose result in a slowly proceeding impairment or destruction of the secreting function of these organs.

The proposal to deal with this condition surgically is, at the present day, a reasonable one. Under antiseptic precautions, the kidney may now be explored, and, if found necessary, the capsule divided to a limited extent with very little risk to life. It would be better to undertake such a risk if a chronic albuminuria, an invalid life, and the prospect of slowly disorganizing renal tissue could be averted by such means. Cases that have been recorded by Dr. Newman, of Glasgow, in addition to my own and others that have been published, tend to support the conclusion I arrived at some years ago in reference to this point. Sir William Roberts, in a letter to me shortly before his lamented death, seemed to think that the suggestion I ventured to make might be the means of leading to a considerable revision in our views on kidney pathology and treatment.

I have undertaken to bring this subject forward for discussion in the Surgical Section of the British Medical Association at Cheltenham next July, and I am very pleased, as president of the section, to ask those of my friends here to-day who may find it convenient to be present to take a part in these proceedings, either by word of letter or of mouth. I may state for your information that I propose submitting this matter in the form of two questions: *First*, To what extent may kidney tension, as seen in kidney congestions, be responsible for permanent structural damage to these organs, which may ultimately result in their chronic degeneration, as observed in some forms of Bright's disease? That is to say, is there such a condition in pathology, to coin a term once put in my mouth by a friend much interested in this subject, as pernicious renal glaucoma? *Secondly*, Under what circumstances, if any, is the removal of tension by a surgical proceeding expedient and justifiable?

In the last place, I must not fail briefly to notice what antiseptics have done for the surgery of the urinary organs and the influence we may forecast that they may exercise on further developments, both in pathology and treatment.

Probably no set of organs has shared in these benefits more largely than the entire urinary apparatus. The complex nature of the urine and its liability to excite sudden and violent symptoms of septic invasion under certain conditions are well known. They are such as we might suppose, though varying greatly in degree, could only be aroused by a virulent and fatal poison belonging, for instance, to the alkaloid group. We see this occasionally occurring unexpectedly after comparatively slight operations, such as the passing of bougies and catheters and other urethral instruments, and more frequently after internal urethrotomy. It is our desire, if possible, to keep clear of these. I remember some years ago—I dare not in the face of Lord

Lister's active and progressive scientific life, a life which we hope will be prolonged to its utmost limits, refer to antiseptics as "ancient history," unless used as a term of our sincerest respect and endearment—the late Dr. Palmer, of Louisville, advocating the saturation of the urine with boric acid, before operations, as a means of preventing those accidental developments to which I have just referred. The plan answered well in my hands, and I believe that in this way, by boric acid or by those digestible drugs of this kind, the desired object may usually be obtained.

The study of bacteriology as applied to the urinary organs by Janet, Guyon, and the French school particularly, has already furnished some excellent results, and the diagnosis and treatment of urinary tuberculosis has also progressed under the practical application of these discoveries.

Can it be otherwise when we look around this palatial building, which has been provided through the generosity and philanthropy of Colonel Payne, whose interest in science and humanity have induced him to make this great gift to Cornell. It is a pleasure to see the kind of men and women that are actually working in it, and the kind of work they are doing for us. Would any one of us desire a more enduring monument, whether living or dead, than this?

I must now bring my remarks to a close. I feel very conscious that they are hardly worthy of the occasion. They have been put together at a few hours' notice, and if, as I am sure is the case, they are hardly up to your expectation, I only hope you will just hold up my friends, Dr. Dennis and Dr. Alexander, for my having inflicted this address upon you, as I hope to be on my way to Florida by this time to-morrow, and shall no longer be on hand.

THE PHYSICAL EXAMINATION OF THE STOMACH.*

BY MARK I. KNAPP, M. D.,

NEW YORK,

ATTENDING PHYSICIAN TO THE EAST SIDE DISPENSARY, DEPARTMENT OF DISEASES OF THE STOMACH.

CURABLE diseases of the stomach, it seems to me, can more easily be cured than curable diseases of any other organ, provided a correct diagnosis is made. It is the correct diagnosis that is absolutely necessary—the same as in diseases of any other organ. So definite are the methods of controlling and of examining each and every function of the stomach that hypotheses and presumptions regarding them should under no circumstance be allowed. Especially is this so if we reflect upon the very great bearing of the function of the stomach upon the entire constitution. To say that at least four fifths of the chronic diseases have their primary cause in the de-

*Read before the Eastern Medical Society, February 8, 1901.

rangement of the functions of the stomach is putting it rather mildly. The well-digesting stomach supplies good material to the blood; the opposite results under contrary conditions, blood supplied with bad materials means bad blood, and where bad blood will strike first we do not know. This last sentence may not sound quite æsthetic or scientific enough, but holds true, nevertheless. Many an obscure case accounted for as due to idiosyncrasy, as neurasthenia, as nervous, or as hysterical—terms, in most cases, the synonyms of ignorance—will, if properly searched, reveal some abnormal condition of the digestive organs which we may correct, and thus cure the disease. To cite but one instance, I would mention the so-called nervous headache, from which the writer of this paper suffered for so many years, but which ceased after proper attention to the stomach.

For the proper diagnosis of diseases of the stomach, the examination both of the fasting stomach and of the contents of the organ after a test meal is absolutely essential; this examination, however, must be preceded by the physical examination of the organ in question, the anatomical position of which might well be remembered.

The stomach is situated in the left hypochondrium and in the epigastrium. We distinguish three parts of the stomach: The cardiac, the part which is continuous with the œsophagus; the pyloric part, which is continuous with the intestines; and the fundus, a saccular expansion close to the cardia and to the left. The upper margin of the stomach is the lesser, the lower, the greater curvature. The superior surface of the fundus, when not collapsed, lies in the dome of the diaphragm, in the fifth intercostal space, behind and slightly above the apex of the heart, and almost entirely shielded by the ribs. As to the position of the stomach, I agree with the majority, who hold the opinion that the stomach lies in the transverso-oblique position. Some dispute this and believe the normal position of the stomach to be the vertical one. There is also some difference of opinion as to the exact level of the greater curvature. According to Pacanowsky, the level of the greater curvature is about three centimetres above the umbilicus; but as the greatest physiological latitude may be taken, the level of the umbilicus—this opinion being held now by Ewald and his pupils, one of whom I have the honor to have been. Cases of gastromegaly are exceptions and cannot be considered here. The pylorus lies on the right side of the median line, under the liver, near the end of the cartilage of the eighth rib, and cannot be felt ordinarily.

The examination of the stomach has for its object to determine the physical, chemical, and dynamical qualities of the organ. The physical examination has for its purpose to define the position, the size, the sensitiveness, and gross abnormal anatomical changes, if any; the chemical, the secretion; and the dynamical, the motility of the stomach. For the physical examination we use the ordinary means of physical diagnosis, for the

chemical we employ certain reagents, and for the motility we use as a guide the relative time consumed by the stomach in emptying its contents into the duodenum.

The physical examination of the stomach, unlike that of the chest, gives but relative values, yet by the senses of sight and touch we may arrive at very valuable information. It is of essential value for the examination to have the intestine, especially the colon, clear of fæcal matter. Neither inspection nor percussion, nor even palpation, can give us with certainty the looked-for information; no better do we fare with inflation or gastrodiaaphany. Valuable, indeed, are the data we get by such examination, but seldom are they in themselves absolutely trustworthy. The cause of this lies in the great motility of the organ, the position of which varies with the degree of its repletion and with the quality of its contents. From the results reached by an examination of an empty stomach we cannot conclude upon its condition when it is only partially or totally filled or distended, and *vice versa*. To make our deductions right, we must always examine under the same conditions. With our greater experience in physical examination will also increase the value of our results so obtained.

The physical examination of the stomach, like physical examinations elsewhere, calls into play our senses of sight, hearing, and touch, in the form of inspection, percussion, and palpation. Auscultation has little if any value in the physical diagnosis of disorders of the stomach. In addition to these methods, we employ stomach inflation, sometimes sound palpation, and transillumination.

The proper position of the patient during the physical examination of the stomach is the recumbent one. When the examiner is palpating, the chest of the patient is slightly elevated and the thighs are somewhat flexed upon the abdomen, in slight abduction. The relative amount of adipose tissue facilitates or impedes the examination, the most favorable condition for the physical diagnosis being a thin-walled abdomen.

The first to be considered is inspection, which, as a rule, gives little information; on the other hand, it may prove a very valuable aid. Inspection must not only be made to consist in looking at the patient from in front, but also in looking at him from the side and from the back over his shoulders. Very often standing at a distance from the patient will tell us more than when near him. In the latter case we can much better perceive slight elevations and depressions; even the lesser curvature in gastroptosis can then be seen as a shadow moving with the respiration. In thin subjects the contour of the stomach can well be seen. Normally, the region of the stomach is full and slightly convex; in gastroptosis this region is depressed, because of the absence of the stomach, and this can readily be appreciated by inspection, which shows the depression in the epigastric region and below it the convexity of the stomach. In very thin subjects with gastroptosis and gastrectasy, both the lesser

and the greater curvatures can be seen, even the thickened, tumefied pylorus, the cause of the dilatation. Tumors, if of sufficient size and situated on the anterior wall of the stomach, can likewise be seen rising and descending with the respiration, this latter, however, only when there are no adhesions preventing such rising and descending. In proper cases the peristaltic movements of the stomach can be seen, when gastrectasy may very strongly be suspected. Normally, peristalsis of the stomach cannot be seen. Kussmaul's peristaltic unrest is due to retained food, which the hypertrophied stomach tries to force through some obstruction, usually located at the pylorus, but sometimes beyond the pylorus, in the duodenum. This peristaltic unrest may become apparent immediately on uncovering the abdomen, or, if not yet visible, may be induced by either sharply striking the abdomen or giving effervescent draughts. The inspection, however, cannot be considered complete unless cognizance is taken of the entire appearance of the patient. Is the patient robust? Is the patient lean, emaciated? Has he a healthy color, or is he extraordinarily pale or cachectic? Such observations are of decisive value and may speak volumes. An emaciated subject, a little bulging in the pyloric region, better appreciated when looking at the patient from some distance, a cachectic appearance—and the diagnosis of cancer of the pylorus will be more than a guess.

Of hardly less importance is percussion. Percussion of the stomach has for its purpose to ascertain its dimensions and the quality of its contents. The results obtained from percussing the empty stomach will differ from the results got by percussing a full stomach; therefore the necessity of percussing both the empty and filled stomach becomes evident. The percussion ought to be done with the patient in the recumbent and then in the standing position, and the results will vary accordingly. If there is any chyme, this will change its level with the various positions of the stomach, and for that reason percussion ought to be practised in more than one position of the patient. The percussion note will differ with the quality of the gastric contents, and accordingly as the gastric contents differ from the contents of the intestine. The air-filled colon will therefore be of considerable influence upon the percussed stomach, and consequently the percussion must be executed with very slight force.

We must, *a priori*, recognize that only that part of the stomach can be percussed that is in apposition with the abdominal wall, and conclusions cannot be drawn from this as to the part covered by the liver and the spleen.

Percussion of the empty stomach may or may not give us the desired information concerning the stomach itself. But it does instruct us concerning the position of the adjacent viscera, viz.: The lower border of the liver, of the heart, and of the spleen. Percussion of the chyme-filled stomach gives us different notes of reson-

ance, varying with the position of the patient. If the patient is in an easy, recumbent position, with the knees drawn up, the stomach being only partly filled, percussion of the anterior portion of the organ will give tympanitic resonance, while on the left side of the abdomen, corresponding to the fundus ventriculi, we elicit a dull note. This phenomenon is simply due to gravity, the chyme gravitating down to the lowest level of the fundus. If now the patient is put on his right side, this side will be dull and the fundal portion tympanitic. In this way we have a double control and a means for a distinctive diagnosis between affections of the stomach and those of adjacent viscera. To better distinguish the percussion sound of the stomach from that of the colon, Pacanowsky recommends the introduction into the stomach of a small quantity of carbonic-acid gas, which gives to the stomach a deeper note than the colon emits.

In percussing the stomach, it is of like importance to ascertain both the vertical and the horizontal diameters, as sometimes a dilatation of the organ will be in the transverse instead of the vertical diameter. If no ptosis of the stomach is present, the determining of the height of the lesser curvature is at present impossible, as we, as yet, have no adequate means of so doing, but the level of the greater curvature must be sought and determined. If the greater curvature is found on a lower plane than is normal, we must attempt to find the level of the lesser curvature, as then a distinctive diagnosis will have to be made between gastroptosis and gastrectasy. To me it seems that the best method to determine the level of the greater curvature is, first to empty the stomach completely, then have the patient take about 150 cubic centimetres of water, and next to determine the level of the water, the patient standing, by the dull note on percussion, and then corroborate in another position, with a different percussional result. This amount of water is sufficient to give percussion results, but not enough to cause the greater curvature to be weighed down.

Before proceeding to the third method, that of palpation, I shall call attention to two sounds produced in the stomach in the presence of air or gas. They are the succussion and the gurgling or rumbling sounds. The first can be produced in the stomach when this viscus contains air or gas and liquids. This succussion sound cannot occur in the presence of but one alone of either of these classes of substances. This sound is normally present after the imbibition of fluids or after meals within the period of digestion. It becomes abnormal only when elicited at a time when the stomach is supposed to be empty. The extent of this succussion sound can likewise be utilized for the purpose of determining the limits and the size of the stomach. The pathological significance of this sound becomes apparent when we consider that, besides chyme, air or gas also must be present at a time when the stomach is supposed to be empty. Such a condition can obtain only when

there is delay in the propulsion of the gastric contents into the gut either by the intrinsic motor fault of the stomach itself, the outlet of the stomach remaining patent, giving the ordinary condition of myasthenia gastrica, or by some obstruction at the pylorus or beyond, in cases of gastrectasy, or by both. Foul odors belched up by the stomach will suggest decomposition of the chyme, by either long delay or other causes, and such a history will at once arouse our suspicion and give us imperative cause for microscopical and chemical examination of the gastric contents. If the belched-up gas has no odor, the supposition is that it is only air or carbon dioxide, and, while this latter may not cause us to apprehend any grave organic lesion, the cause must be investigated. This belching up of air may indicate a general nervous disposition, a hasty gulping down of food with the mouth wide open at every bite, thus admitting large quantities of air, or, secondly, it may mean the insufficient closing of the cardiac opening of the stomach; this remaining open, admits air, which normally finds its way into the œsophagus, but is checked from further progress by the closed cardia. Again, the belching up of carbon dioxide may be due to acid gastritis, in which case the mucus is being attacked by the acid, with the evolution of the gas as one of the chemical results.

The succussion sound may also be produced in the intestine, in which case the emptying of the stomach with the stomach-tube will clear up the diagnosis. If the stomach-tube shows the stomach to be empty, and the succussion sound still persists, the succussion sound is outside of the stomach; it is in the intestine. This sound is produced by sharply and quickly striking the gastric region with the tips of the fingers, and may be produced involuntarily by the patient himself by a sharp motion of his body, or also voluntarily by alternate contractions and relaxations of the abdominal muscles. The recumbent position is the best for eliciting this phenomenon.

The gurgling sounds of the stomach are produced in an air-filled stomach, no liquids being present. Some patients can produce them at will. The rapid and alternate contractions of the abdominal wall upon an air-filled stomach are the causes of the gurgling. This sound has no pathological significance whatsoever.

The most important and the most difficult of all the methods of physical examination is palpation. No rules can be laid down by which palpation can be taught. Experience under prudent and frequent guidance is most important for the study of palpation. There is no law that will supplant the palpating fingers.

The position of the patient is as above described, on his back, with the abdominal muscles relaxed and breathing somewhat quickly and deeply; *long*, deep respirations interfere with palpation. In some cases the palpating of the patient in a side position, or in the knee-elbow position, or even in the standing position, may at times be resorted to with benefit.

The examining physician sits at the right side of the patient, who lies easily on a high couch. The couch must not be too high, nor should the physician stand while palpating. The palmar surface of the palpating hand must be placed on the patient, the metacarpal bones of the hand forming only the prolongation of the axis of the forearm, and not an angle with it. The entire forearm and hand must be in a horizontal line, the forearm possibly slightly and gently resting on the patient. The examining hands of the physician must not be cold, as cold hands will cause a contraction of the abdominal muscles of the patient, and thus frustrate our efforts, besides causing an unpleasant sensation to the patient, a thing we must always avoid, if possible. We feel with the palmar surfaces and tips of the last phalanges. The examiner must hold his fingers in an easy position; he must not strain the extensor muscles of his fingers while palpating, as straining them will interfere greatly with the tactile sense of his examining fingers. No force or great pressure should be used in palpation. We simply glide our fingers over the abdomen in a somewhat to-and-fro, rotary motion, applying but very gentle pressure, and gradually and carefully going deeper, as becomes necessary, bending the last phalanges. The gentler the palpation, the better we can feel. Too forcible pressure is almost invariably made by the beginner, who does his best to "grasp" the situation, and by such forcible pressure causes the abdominal muscles to contract, so that their margins, coming prominently into "view," simulate tumors.

For palpation we may either use the fingers of both hands simultaneously or we may use only one hand for palpation and the other, superimposed on the palpating one, to give to the lower, feeling hand the necessary pressure; or, again, we may use one hand only. Often we feel with but one hand and with the other try to bring the part or object to be palpated toward the palpating hand.

We palpate for the following reasons: For defining the size and position of the stomach and its relation to other organs, for evidence of pain, for gross pathological changes, and for tumors. In a thin-walled abdomen, especially in cases of thin, multiparous women with the condition known as *diastasis recti*—i. e., divulsion, separation of the recti abdominis muscles—we may well be able to feel the greater curvature of the stomach. The greater curvature of the stomach may also be felt by the method known as sound palpation, which method consists in introducing a stomach-tube into the stomach and then feeling the tube through the abdominal walls, the tube, as frequently demonstrated, coursing along the greater curvature. It should not, however, be too hard to feel the greater curvature of a more or less empty stomach in patients with little adipose tissue. We very often may mistake the greater curvature for the lower border of a supposed ptotic liver, but percussion will help us out in showing tympanitic resonance of the

same quality above and below; the hardness we do feel, and the flat note it gives on percussion is due to the necessary double thickness of the apposed walls of the viscus.

Riegel advises two methods for palpation: The first for the purpose of acquainting one's self generally with the size and position of the stomach; the second one to diagnosticate localized areas. For the first method Riegel advises laying the slightly curved hand on the abdomen, the ulnar side of the hand turned downward and adapting itself to the surface of the abdominal wall. It is moved from above downward in a stroking manner. After some endeavors we may be able thus to feel the ventricular walls, especially in cases of gastrectasy and atony. This method, Riegel admits, cannot be executed when the stomach is absolutely empty, but it must always be filled to some extent by gases or ingesta. After trying this first method, we proceed with the second, using our finger tips, somewhat perpendicularly to the abdomen. In this way localized areas can better be felt.

Before proceeding with palpation for tumors, we must bear in mind the occupation of the patient, as this quite often has a decided bearing on the development of the abdominal, especially the recti, muscles. Either one or both these last-mentioned muscles may, by occupation, be hypertrophied, or only parts of the muscle, between two of the transverse tendinous lines that cross the recti abdominis. The first sections, those between the ribs and the first transverse lines, are the most often so hypertrophied. Such an hypertrophied section may indeed be mistaken for a serious condition. It is always best, in suspicious cases, to compare the suspected side with the other. Evacuation of the patient's bowels before examining him will always be of use, as accumulated fecal matters will simulate tumors. Not so easy, if at all possible, is the diagnosis of "passive fat tumors." By this expression Senator means that isolated pieces of fat remain, while general atrophy of the fat of the body occurs. Such passive fat tumors do occur, and their diagnosis is difficult, if not impossible. Temporary "gas tumors" are freely movable tumors, sometimes felt in the region of the stomach, when the intestines lie in front of the stomach, and they are produced by the spastic contraction of the circumference of the intestine at two points, apart from each other. They include air or gas. It so happened that in palpating one patient I felt a distinct tumor, well circumscribed and passively movable. While attempting to locate and diagnosticate that tumor, suddenly I felt the tumor dissolve, accompanied by the peculiar crackling sound of emphysema of the skin. This phenomenon repeated itself during the examination. The tumor proved to be nothing but a localized, temporary, gaseous cyst of the intestine.

The bore of every novice in palpation is "aneurysm of the abdominal aorta." This diagnosis is a very frequent one with every beginner. He nods assent when his attention is called to the mistake, but, indeed, he

does it half-heartedly, until he gradually learns to recognize his mistake. Especially is the beginner led into mistakes when the conditions for palpation are favorable, as in lean subjects, and especially in cases of diastasis recti. He feels the pulsating abdominal aorta, which is covered by the tissues overlying it. These overlying structures naturally increase the thickness over the aorta, so that the covering is forgotten and everything taken as one pulsating mass, which is diagnosticated as aneurysm of the abdominal aorta.

Having diagnosticated a tumor, the following questions arise: What is the consistence of the tumor, what is its size? Is it unilocular, is it multilocular? Is it freely movable, or is it partially or entirely adherent to the circumjacent structures? Where is the tumor situated? Is the pylorus, as is by far most frequently the case, the seat of the neoplasm, or is it the lesser curvature, which comes next in frequency, or the anterior or the posterior wall of the stomach, or is the tumor *ad cardiacam*? A tumor *ad cardiacam* can sometimes be felt, but, if it is not of sufficient size, the characteristic history pointing to a tumor of the cardia must be confirmed by the œsophageal sound. If a tumor is felt, and the question arises as to whether that tumor is on the anterior wall or the posterior, then such question may be decided by examining the stomach both empty and filled. If the tumor is felt best when the stomach is empty, the diagnosis of tumor of the posterior wall will be a proper one. If, however, the tumor is best felt when the stomach is filled, then we have to deal with a tumor of the anterior wall. It is just here in trying to locate a tumor and ascertain its motility that the patient is put in different postures. The knee-elbow position is very well adapted for the diagnosis of tumors of the anterior wall of the stomach.

There are two more methods for the physical examination of the stomach. The one is distention of the stomach by carbon dioxide or air, and the other is transillumination of the stomach, gastrodigraphy. The purpose of either of these is to supplement or to corroborate the other methods of physical examination, to define the position and the size of the stomach, especially when a diagnosis between dilatation and ptosis is to be made. The inflation of the stomach will also show the condition known as the hour-glass contraction of the stomach. If a tumor is felt, the distention of the stomach by air or gas will show whether the tumor belongs to the stomach or to another organ, as the tumor will change its position with the changed condition of the inflated stomach. If a tumor belongs to the posterior wall of the stomach, the distention will cause such tumor to disappear under the touch.

Carbon dioxide was first used by Fenwick in 1868, who gave small and equal doses of bicarbonate of sodium and tartaric acid in water. The gas evolved in the stomach by these chemicals distended the stomach and gave a different percussion note, the purpose for

which it was used by him. Instead of bicarbonate of sodium and tartaric acid, a glass of ordinary carbonic acid water answers equally well. When gas generation in the stomach is used, three quarters of a teaspoonful of the tartaric acid is first given in water, and immediately after a teaspoonful of the bicarbonate of sodium, also in water. This method has this merit: We need not introduce the tube into the stomach, a fact which must not be underrated. Especially is this method of value when there is a tumor *ad cardiam* and the tube cannot be introduced for the purpose of inflating the stomach. The drawback to the use of this artificial gas production within the stomach is that we can never fully know how much gas we are to produce, and any overdistention of the stomach may give rise to distressing—nay, even alarming—symptoms. Nevertheless, neither Riegel nor other authorities have met with any accidents in the constant use of this method. It is different with the introduction of air into the stomach, first employed by Runeberg. This is done by introducing the ordinary stomach-tube into the stomach and connecting the proximal end of the tube with a double rubber bulb. This method has the advantage that the degree of the distention of the stomach is always at our command, and the patient can instantly be relieved from any overdistention by simply disconnecting the rubber bulb and allowing the air to escape, helping by pressure upon the stomach. The volume of air in the stomach in this method can be regulated at will. The disadvantage of this method is the fact that we have to insert an instrument into the stomach. This is the method now used by Ewald, and, while it has always proved successful, it has never given rise to any alarming symptoms. It certainly is the method to be recommended if we find no objection to the tube and if the tube has a free passage into the stomach. By the distention of the stomach we are well able to see its contour, as the entire organ becomes prominent.

The next method is gastric transillumination, discovered by Milliot in 1867, and used by him in experiments on animals. For its use on man, gastrodiaphany was developed and introduced by Einhorn, of New York, in 1889. The principle of gastric illumination consists in introducing into the stomach, filled with water, a small electric lamp. The gastrodiaphane is essentially a small Edison incandescent lamp attached to the end of an ordinary stomach-tube, the electric wires running through the lumen of the tube. It is of importance that the stomach be first emptied and washed out. It is then filled with lukewarm water to its full capacity, and then the gastrodiaphane introduced. The purpose of the water is not only to prevent overheating by the lamp, but to give a good picture; little water does not give good results. The room in which transillumination of the stomach is done must be darkened. The patient may be in a recumbent or in a standing position; the examination in both positions is to be advocated. In the nor-

mal or in the dilated stomach the transillumination shows the greater curvature, the lower margin of the liver, and the moving diaphragm, sometimes also parts of the intestine. We can see the stomach rise and descend with respiration. In the ptotic condition of the stomach we see the lesser curvature as well, but the stomach does not move up and down with the respiration. The diagnosis between gastropnoia and gastrectomy is made mainly on the strength of the presence or absence of the respiratory movements of the stomach. Tumors of the stomach may sometimes be discerned by gastrodiaphany by dark, not transilluminated areas and spots.

136 EAST SEVENTY-EIGHTH STREET.

INFECTIVE SIGMOID SINUS THROMBOSIS.*

By CLARENCE R. DUFOUR, PHAR. D., M. D.,

WASHINGTON, D. C.,

OPHTHALMOLOGIST AND OTOLOGIST TO THE EASTERN DISPENSARY AND CASUALTY HOSPITAL; SIBLEY HOSPITAL, ETC.

IN selecting this subject this evening, I have done so with the full knowledge of its comprehensiveness, and conscious that within the scope of my paper I can only give the salient features of its symptomatology, diagnosis, and treatment, and cannot go into the details of the subsequent operations found necessary after exposing and opening this sinus; for in an operation of this character one should be prepared to explore and operate upon the various parts of the cranial cavity likely to be affected from this condition by extension.

The sigmoid sinus is more often affected with thrombosis than any other of the sinuses, on account of its nearness to the middle ear, mastoid cells, and antrum, cavities that are so liable to purulent inflammation. Thrombosis of the sigmoid and lateral sinuses is rare in infants, is seen seldom in children, is common in adults, and rare in old age. In infancy the mastoid cells are not developed, as a rule, though the antrum exists; the squamomastoid suture is pervious, therefore the purulent secretions find their way through it. There are more exits for venous blood in infants, as compared with adults, and, lastly, the sinus is not embedded in an osseous canal, but rests upon a flatter surface than in adults. Infants are more prone to pathogenic involvement of the inner ear, by extension from the middle ear, causing leptomeningitis, which often terminates fatally before a thrombus of the sigmoid sinus develops. The ætiology of this condition is from extension of chronic purulent otitis media; extension of thrombosis from other sinuses; traumatism, such as a fracture passing from the base of the skull to the middle ear; infection from septic wounds of the head, neck, or mastoid region, and inflammatory secretions from throat or naso-

*Read before the Medical Society of the District of Columbia.

pharynx into the middle ear, antrum, and mastoid cells. The most common cause is through an infective inflammation from the middle ear, producing infective thrombosis of the small veins, going from the middle ear to the sigmoid sinus, or by direct erosion of bone. A discharge from the ear may be present for years, during which time a slow erosion of bone may be taking place, causing it to become thin, and the mastoid cells and antrum to fill with granulations, with little or no pus formation. Again, the veins of the middle ear may become thrombosed, and this condition may extend to the sigmoid sinus with little, if any, effect upon the bone. A large number of persons are affected with chronic suppurative otitis media, and it is from these persons that a large number of the cases of infective intracranial diseases come. Rohrer found a distinct difference in the bacteria of foetid and nonfoetid discharges from the ear. In the nonfoetid, micrococci only were found; in the foetid, both bacilli and micrococci were found. He also found that the bacilli in foetid discharges possessed only saprophytic properties, but that inoculation with the micrococci produced fatal sepsis. Gruber very pertinently says that "the offensiveness of the discharge is no criterion of the dangers that are to be apprehended from it." A chronic suppurative otitis media is more liable to cause infective intracranial conditions, because the resistance of the tissues is impaired, and the lining membrane of the tympanum and the accessory cavities has been partially destroyed, necrosis of the bone existing in places; thus the blood-vessels and lymph channels are rendered liable to septic infection and to carry this condition to other organs by means of the circulation. Acute suppurative otitis media is not so liable to cause this condition, for the periosteum is a protection against bacterial invasion, and the leucocytes play an important part in destroying the phagocytic action of the micro-organisms. Monti has demonstrated that weak cultures of staphylococci, which produced no results when injected subcutaneously, caused fatal sepsis in a very short time when nonpathogenic germs were injected with them. This may be the explanation of the fact that a discharging ear that has been long dormant, sometimes suddenly becomes active to a very serious degree by the introduction into it of some other germ, be it pathogenic or not, which causes a septic condition of the entire system or manifests itself in some localized affection of the brain or its covering. This condition may be divided into three stages, the manifestations of each being more severe in character than those of the preceding one. The beginning of a thrombus of the sigmoid sinus rarely has any symptoms pointing directly to it, other than the mastoid symptoms which demand the opening of the bone. They are: Hemicrania, persistent in character; pain on pressure over the antrum; the auricle stands out prominently from the head; sagging down of the posterior superior wall of external auditory canal, and fever. It is after

the mastoid bone has been opened, cleaned of pus, granulations, etc., that the sinus is exposed and inspected when it is frequently found thrombosed, the bone being carious, extending through the inner table, and encroaching upon and surrounding the sigmoid groove. When there is, or has been, a chronic purulent otitis media, and the discharge has, or has not, ceased, and there is a persistent hemicrania with fever, rigors, nausea, and vomiting, the sinus should always be carefully inspected when the mastoid bone is opened. The second stage of this disease follows quite rapidly, should there be no operative procedure in the first instance. It is usually ushered in by a pronounced rigor; in this stage the thrombus has broken down, and the septic matter has become absorbed, causing constitutional symptoms, most prominent of which are frequent rigors and fluctuating temperature; to discover the latter, the thermometer must be used every three hours and an accurate record kept. The symptoms of this stage are those of septic infection, the copious sweating, exhaustive in character, the anxious appearance of the face, constipation, irregular respiration, slow and fast at intervals and the before-mentioned rigors and fluctuating temperature. There are no uniform or specific symptoms which determine the presence of a thrombosis of the sinus that may not vary in such a manner as to cause doubt as to the condition present. It is here that experience in many cases will be of great assistance; there are certain symptoms, or manifestations, which have come to be regarded as indicating a thrombus of the sigmoid sinus by the regularity of their presence in most cases. In this, as in other conditions, a chain of symptoms are taken together and used in making a positive diagnosis. In enumerating these symptoms, the rigors or chills are probably the first to become manifest; they usually increase in frequency as the septicæmia increases, they may recur daily or several times a day, and are usually accompanied by a very exhausting sweat which leaves the patient more and more prostrate. These sweats may become continuous, always present though the temperature is high, differing from other fevers in which the skin is hot and dry. Sometimes the rigors are absent and the sweats also; in these cases the septic absorption is not so great. Allen has reported a case in which no sweating took place until shortly before death, though rigors were present. This case shows the variability of this symptom, and that it alone is not an infallible sign. The fluctuating temperature is regarded as a very important and significant symptom. The pulse rate is high, from 150 to 175; the very rapid movement of the blood will soon cause unfavorable developments, not only of temperature, but of respiration, the latter becoming rapid and labored. Vomiting or dizziness may, or may not, be present. Meningitis may occur; when it does, these last two symptoms are usually present. The patient may become unconscious or delirious, or may remain conscious up to the time of death.

or, again, may become lethargic and semiconscious, from which condition he or she may be aroused, may reply to questions, and then sink again into this semiconscious condition. A mild form of delirium may appear, which is not indicative of a serious condition, unless the patient becomes violent. This delirium is caused by non-infective emboli in some of the small cerebral vessels. Edema of the mastoid region has no significance as regards thrombosis of the sigmoid sinus; this œdema is usually caused by a periosteitis of the mastoid bone; though a blocking of the veins in thrombosis may tend to increase the œdema. In subperiosteal abscess there is considerable œdema. There is often present an œdema of the occipital region, extending down the neck, which is caused by an obstruction of the occipital and mastoid veins, and by a phlebitis of same vessels. This is known as Griesinger's symptom, and, when present, is significant of sinus thrombosis. There sometimes occurs an œdema of the temporal region involving the upper eyelids on the same side, and often associated with ecchymosis; this is due to the phlebitis and thrombus extending to the cavernous sinus of that side. The involvement of the ocular muscles, and the partial or total loss of sensation of the same side of the head, point more fully to the cavernous sinus being implicated; both sides may become infected by extension through the circular sinus. The ocular muscles affected are usually those controlled by the third, fourth, and sixth cranial nerves, which are on the outer and inner side of the cavernous sinus respectively; the first division of the fifth nerve, which supplies sensation to the temporal region, eyelids, etc., is also on the outer side of the cavernous sinus. Pain on pressure on the mastoid is more indicative of a periosteitis of that particular bone than of a thrombus of the sigmoid sinus. Pain on pressure along the course of the internal jugular vein and upon the upper third of the posterior cervical triangle can often be elicited; this pain is usually so severe that the patient will wince under the pressure, even though he or she is semiconscious or somnolent. This is a very important symptom, and, when present, indicates a phlebitis and thrombus of the internal jugular, and probably of other veins in the neck. Comparison of the two sides, as to the degree of pain induced by pressure, will often give valuable information when in doubt as to the condition of the sinuses. The pain may be more intense on one side, but painful on both; this may indicate a beginning phlebitis in the other jugular by extension. Frequently the internal jugular can be felt in the neck like a cord, when it is thrombosed; it will be felt to the inner side of the sternomastoid muscle; the upper third of the vein is mostly affected, but often the thrombus extends throughout the entire vein, to its junction with the subclavian. The most serious stage of this disease is that of disintegration and breaking down of the thrombus, so that particles of it are carried into the circulation and induce metastasis to other organs,

especially the lungs, causing pulmonary infarctions. Where this occurs the symptoms increase in severity, the rigors are increased and more severe, the fever becomes higher, and the exhausting sweats more profuse. The pulmonary manifestations begin very insidiously, dyspnoea and a slight cough being the first symptoms that appear; then pain in the chest on one or both sides, according to the amount of lung tissue involved; these symptoms are usually followed by the rusty-colored sputum and moist râles, the former having an offensive odor and bacteria being found in it, the most prevalent of which are the staphylococci, streptococci, and pneumococci. The lungs may become gangrenous and abscesses form in them, as well as in other parts of the body. Septic enteritis frequently occurs during this stage, and may be diagnosticated as typhoid fever, from the fact that the general history and symptoms of septic thrombosis may have been obscure or absent, and from the failure to recognize the otorrhœa as the cause. The symptoms of this type of this disease are similar to those of typhoid fever, viz., the furred tongue, loss of appetite, fluctuating temperature, and diarrhœa; the discharges from the bowels partake often of the odor of the otorrhœa, the prostration is great, and delirium soon appears. The diagnosis between septic enteritis and typhoid fever lies in the recognition of the otorrhœa and the mastoid symptoms, the absence of the rose-colored spots, the character of the temperature being more fluctuating, the difference of from four to six degrees occurring in two or three hours. The infective matter is often carried to the lungs and intestines by passing through the Eustachian tube into the pharynx, the stomach, intestines, and some of it may find its way into the lungs through the trachea and bronchi. The patient may, or may not, be conscious. Meningitis is liable to develop, if not present earlier in the course of the disease; when present, it sometimes masks the symptoms of the thrombosis. Neuroretinitis occurs very frequently, and is always present when meningitis or other brain complications arise.

Metastatic abscesses of other organs, viz., of the liver, spleen, and kidneys, occur with a certain degree of frequency. Peripheral abscesses are liable to form, and careful scrutiny of the entire body of the patient should be made, especially of the joints, in which these abscesses are so liable to form. It is fortunately the case that all the metastatic inflammations do not result in abscesses; many of them undergo organization and constructive metamorphosis. Whether a purulent accumulation in one or more of the vessels can, or does, cause reinfection from that particular point is a matter of individual opinion; statistics do not confirm this theory.

Diagnosis.—In the foregoing I have given the majority, at least, of the symptoms of infective sinus thrombosis, which, when present, enable us to make a pretty certain diagnosis, yet many of them may be absent or so obscure as not to be recognized. Therefore the ques-

tion arises: Which of them are to be relied upon, by their presence with a certain degree of constancy, to warrant a diagnosis of this affection? It is important that this condition should be recognized at its beginning and before the system is overwhelmed with pyæmia and the metastatic stage has begun, if we wish to treat it successfully. The majority of the fatal cases of infective sinus thrombosis are those that have not been operated on until late in the second stage, because, in the first stage, there was nothing to point to that condition of the sinus; no sign whatever of septic infection, but only those of uncomplicated mastoiditis were manifest, which gave no signs of intracranial invasion. The first stage is the one most favorable for operation; therefore all the features, symptoms, etc., of this favorable period should be familiar to us, that we may operate at once before the other stages set in, increasing the gravity of the condition of the patient and exaggerating the danger of a fatal termination.

In recapitulation, I would emphasize the following symptoms of infective sinus thrombosis as those upon which we should rely, and, when present, should act promptly and decisively, since delay is dangerous. When, therefore, a patient has a purulent otitis media, and there is an increase or decrease of the discharge, hemicrania appears, and a general systemic disturbance of greater magnitude than is usual in mastoiditis occurs, we should suspect an intracranial condition, and our suspicion, converted almost to a certainty should a chilly sensation or a pronounced chill or rigor take place, followed by high temperature fluctuating in character, profuse sweat, exhaustion, rapid pulse, and respiration, together with the following local signs, would confirm a positive diagnosis: Tenderness in the upper third of the posterior cervical triangle, occipital œdema, tenderness along the course of the internal jugular vein, neuroretinitis, œdema of the eyelids, and a cord-like feeling of the inner jugular vein, extending into the neck.

Operation.—In this, as in other intracranial operations, asepsis is absolutely necessary. The patient's head—and beard, if any—should be shaved, the parts scrubbed well with soap, afterward with a solution of bichloride of mercury, 1 to 5,000, and lastly with ether, and an aseptic bandage should be put over the site of operation. This should be done, if possible, the day before, or at least a few hours before, the operation. Proper attention should be given to the diet of the patient. The bowels should be well moved the day before the operation. Whether we should operate in the morning or evening is a matter of individual choice; when the conditions and circumstances admit of a choice, my preference is for the morning. The operator, assistants, and nurses should observe all the recognized methods of rendering their hands aseptic, and should wear aseptic gowns and caps. The patient on whom is to be done an operation for infective sigmoid sinus thrombosis is one who is in a septic condition, and has been so for several

days; whose physical condition is greatly impaired and his vital energies at a low ebb. The operation is a grave one, and the shock from it, which is mostly caused by the loss of blood, is great; for in cleaning out the thrombus and in removing adhering particles this cannot be avoided; therefore, every detail of the operation must be as complete as possible, and all restoratives at hand.

One of the most valuable of these is the intravenous infusion of normal salt solution at a high temperature, and there should be no delay in using it, especially if the loss of blood has been great; for in it we have a great remedy for the prevention of shock, and a heart stimulant of the best character. I think, also, that it eliminates a certain amount of infective matter or toxins from the blood. This agent should be used in any stage of the operation, together with the proper hypodermic medications, when their use is indicated. Subcutaneous infusion or an enema of the salt solution should be used if there is any delay or difficulty in finding the vein. The operation should be done expeditiously, but nothing should be left undone that ought to be done, unless the patient's condition admits of no further operative procedure.

As to whether the antrum or sigmoid sinus should be first operated upon, the symptoms should be our guide. In my judgment, the antrum should first be opened and cleaned out, then the sinus uncovered and inspected, for, as a rule, the infection is due to extension from middle-ear suppuration. To open the antrum, the incision should be made a quarter of an inch behind the attachment of the auricle, beginning at the tip of the mastoid bone and extending to the posterior root of the zygoma; the periosteum should be pushed aside, the field made clear by ligating or using forceps on all bleeding vessels, and the parts separated by retractors or by sutures passed through them, looped, and held apart by an assistant.

The landmarks must be plainly in view before beginning the operation; they are the spina supra meatum, the linea temporalis, and the posterior external osseous canal. The bone should be entered at the base of the suprameatal triangle, a triangle formed by the posterior root of the zygoma, above, the posterior border of the external osseous canal, below, and an imaginary line uniting these two, extending from the zygomatic root to the most posterior portion of the external osseous canal. The antrum may be entered with safety within the base of this triangle; the opening to be made inward and forward. The antrum is often superficial in children; in adult life it is more deeply situated; its depth often varies from one eighth to three fourths of an inch, and sometimes more. If it is not exposed after penetrating about a half inch, further procedure must be with great care, lest the facial nerve be injured. The opening must be kept within the limits of the triangle before described; it is best not to let it go above the superior bor-

der of the external osseous canal, but to keep it a little below it. The bone should be gradually chipped off with a gouge or chisel, and mallet, or with whatever instrument the operator prefers. The operator must be on the outlook for abnormalities of the skull, for, where they exist, there is danger of injuring the facial nerve or the horizontal semicircular canal, or of entering the middle cranial fossa or opening the sigmoid sinus. We recognize that the antrum is opened when a probe can be passed into the cavity to the depth of from three fourths to seven eighths of an inch, indicating that the probe has passed into the middle ear. The passage between the antrum and the middle ear must be curetted and all necrosed bone, granulations, etc., removed. The ossicles must be removed if they are found to be necrosed. An assistant should be instructed to observe and report any signs of facial twitchings, which indicate a liability to injury of the nerve; it is a wise precaution, especially when there has been much erosion of bone on the floor of the antrum, not to remove any granulations springing from that point without examining them with a probe, to ascertain if the facial nerve is in connection with, or enclosed in, them, the twitchings of the face being our guide. To expose the sinus, the initial incision must be continued backward from an inch and a half to two inches, the periosteum pushed aside, and the parieto-squamo-mastoid junction exposed. The landmarks which guide us in locating the sinus in its different parts are the parieto-squamo-mastoid junction and a line drawn from this point to the tip of the mastoid bone, which indicates the course of the sinus; this line marks the middle of it, or, in adults, sometimes the posterior border only. If the bone is opened with this line forming the posterior border and keeping between the roof and floor of the external osseous canal, the sinus will be uncovered at the part most often affected. The most superficial part of the sinus is found in a line with the roof of the bony canal and lies only one twelfth to one quarter of an inch from the surface, being more superficial than the antrum. The sinus passes deeply into the skull at the level of the floor of the external bony canal. The parieto-squamo-mastoid junction indicates about the point where the superior petrosal sinus joins the sigmoid, and also the upper border of the petrous bone that lies next to the mastoid. The asterion indicates the point of union of the lateral with the sigmoid sinus. The knee of the sinus is situated about half an inch behind the posterior border of the external osseous canal, and about its upper two thirds; this portion is that mostly affected by infective material from the antrum.

If the sinus is to be exposed without opening the antrum, a trephine should be used to remove a button of bone, the centre of which should be at a point seven eighths of an inch behind the middle of the bony meatus, and a quarter of an inch above it. This opening can be enlarged in any direction and can be made

sufficiently large for exploring the temporosphenoidal lobe and the cerebellum.

As the sinus is usually exposed after the mastoid antrum has been opened, the opening in the bone is continued from the posterior wall of the antrum, about a half inch backward and horizontally; this will expose the sinus, and it can then be uncovered in one or more directions, as the operator may desire. Valuable information is often obtained by the external shape of the skull; if the mastoid process is narrow, quite convex, and very prominent, the sigmoid groove is most likely to lie well forward, close up to the posterior wall of the external canal; in some cases only a thin cortex and the inner table lie between the sinus and the periosteum. Again, if the tip of the mastoid is broad and flat, the groove and sinus are to be looked for further backward from the canal wall. After the sinus has been exposed and the groove removed, the next step will be to determine the condition of the sinus, to ascertain if there is an incomplete or parietal thrombus, a thrombus obstructing it in the vicinity of the knee, or one occluding the entire length of the vessel, extending into the jugular vein in the neck. A parietal clot is somewhat difficult to determine, as the blood is flowing through the vessel and the aspirator reveals only blood. Carefully feeling it between the fingers will indicate that part of it in which the parietal clot is present; the affected part feels like thickened tissue as compared to the unaffected part of the sinus. A complete thrombus is easily determined by the sense of touch and by inspection, or by aspiration. The fluid withdrawn may be pus or decomposed blood; the microscope will reveal the presence of any pathogenic bacteria; pure blood is withdrawn when the sinus is normal or only partially occluded. A thrombosed sinus has lost its lustre and smoothness and is usually distended and discolored at the portion containing the clot; granulations are sometimes found springing from its walls, and it does not compress easily, as does an unaffected sinus. Before opening the sinus the field must be well cleaned with an antiseptic solution, all necrosed bone and tissue removed; the sinus may then be opened and split lengthwise. Care must be taken that the visceral wall is not cut through and the brain tissue wounded, thus opening up a pathway into it for pathogenic germs and septic infection. In opening a sinus having a parietal clot, it should be compressed above and below to control the flow of blood, which is liable to be excessive; antiseptic gauze packed between the sinus and its parietal wall, in the vicinity of the bulb, is usually sufficient for the purpose. Pressure should also be made at the distal side by means of gauze held firmly against the sinus by an assistant. The sinus must be cleaned of the clot and all adherent particles by means of a small curette, until there is a free flow of blood from both ends; this tends to wash out all septic matter. The clot must be removed entirely, for, should any of it remain, it is liable to un-

dergo purulent liquefaction, and to necessitate another operation, which will be more serious than the former on account of the additional shock from another excessive loss of blood. If the clot extends into the jugular vein, which fact can be determined by the cord-like feeling in the neck, the vein must be exposed and divided between two ligatures and resected, or the entire clot removed and the vessel walls curetted. When about to open the sinus, the foot of the table should be raised; this will increase the pressure of blood in the sinuses of the dura mater, and will in a great measure prevent air from entering the opened sinus; for, if the patient is lying prone, the pressure in the sinus is very slight, so the hæmorrhage that is likely to occur when it is opened will reduce this pressure still more, and an aerial embolus, with a fatal termination, is likely to be the result. Again, the lowering of the head of the patient will prevent cerebral anæmia and liability to heart failure.

If the sinus is thrombosed to any extent, or if the thrombus has undergone disintegration, the jugular vein should be ligated. This will, in a great measure, prevent septic particles from being carried to the lungs, though the anterior and posterior condylar veins and the occipital sinus will permit small particles of broken-down clot to pass to the lungs. If the jugular is tied about its lower third, the facial vein must also be ligated. In establishing the circulation from the sinus, remember that you will get a flow of blood from the petrosal sinus, which may mislead you to think that all of the clot is removed and a normal flow of blood established. After removing the clot, etc., the sinus must be rendered as aseptic as possible, preferably by means of iodoform or other powder, and the split walls folded inward and held in this position by pressure exerted upon them by means of aseptic gauze. This will close the vessel securely and obliterate its lumen. If the sigmoid is compressed as described for about an inch of its extent, the blood from the superior petrosal and lateral sinus will be cut off, as well as the outflow from the mastoid vein. This method of closing the vessel is preferable to ligating it, as the latter is difficult to do; the needle cannot be passed under it and through the dura mater without risk of passing it through the visceral wall of the sinus, which would nullify our efforts; then, again, the brain tissue upon which the sinus rests, or the meningeal vessels which pass into it, would be liable to be injured or penetrated.

The sinus walls are so thick and dense that any effort made to ligate them is liable to tear them. The wound must be treated as any other septic wound, packed with gauze and allowed to heal by granulation; the metastatic abscesses in the joints, etc., are to be opened and treated in same manner.

The wound in the neck, made in exposing the jugular, must be closed with sutures, leaving a part of it open, which should be packed with gauze and allowed to heal by granulation.

The patient is then put to bed, surrounded with heat,

the foot of the bed elevated, heart stimulants given, preferably hypodermically, and intravenous or intracellular infusion of the normal salt solution administered. The patient is usually in a state of profound shock, and should be treated accordingly. A nurse should be constantly at the bedside for at least the first ten or twelve hours after the operation. The dressings may be left undisturbed for three or four days if no unfavorable symptoms occur. Should the temperature rise and fluctuate or rigors appear, the bandages should be removed, the wound carefully inspected, pus be searched for, and, if found, evacuated; the parts irrigated with an antiseptic solution, and the bandages re-applied, after which they should be changed daily. If there is much discharge from the wound and the dressings become soaked with it, they should be saturated with a solution of bichloride of mercury before removing them. Owing to the length of my paper, I will not go into details of the case that came to me for operation. I will only give a brief summary of it.

Mr. M., white, a man aged forty-five years, had had a discharging ear since childhood. The discharge ceased, hemicrania appeared, he became stupid, was chilly all the time, and the light hurt his eyes. These symptoms continued for several days, when he had a pronounced rigor followed by copious sweating; his family physician requested me to see him, as he said that he thought his condition was due to some ear trouble. I found tenderness in the posterior cervical triangle, pronounced occipital œdema, beginning neuroretinitis, and a fluctuating temperature. I diagnosed the case as one of infective sigmoid sinus thrombosis and advised an operation, which was done. The mastoid antrum was opened, cleaned out, the sinus exposed, and about a half an inch of it was found thrombosed at its knee; a portion only of the bony surroundings was necrosed, which was removed. The sinus was compressed above, opened, the thrombus removed, and the vessel curetted; the loss of blood was not great. The sinus was closed and the patient treated according to the method described. The lungs were not involved and there were no metastatic abscesses. The clot had not disintegrated; the microscope revealed streptococci and staphylococci. The patient made an uneventful recovery. It was a case where the system was not overwhelmed with septic infection before operation. The fundus of the eye cleared up and sight was normal in about eight weeks.

In conclusion, I would enter a plea for the general physician to be on the lookout for symptoms pointing to this condition in those who have a suppurative otitis media; also to bear in mind that a discharging ear, be the amount great or small, is not a simple and innocent matter, but one that is liable at any time to cause grave conditions that may ultimately end fatally, either from infective sigmoid sinus thrombosis, or from some other infective intracranial condition.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

BY NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

NEW YORK,

VISITING SURGEON, POST-GRADUATE HOSPITAL.

(Continued from page 457.)

We have already seen that a frequent morbid condition of the decidua is congestion. That it is extremely frequent there is little doubt. Probably sufficient importance has not been attached to the possibilities. When it is understood that general plethoric conditions and all those associated with passive congestions lead primarily to pelvic engorgements, and that the boundary line between pelvic catarrh and inflammatory processes of the decidua is but a slight one, it will be recognized as a very important symptom. This we will now proceed to consider.

Inflammation of the decidua has been investigated and described by many eminent men, and, although they differ occasionally in their opinions as to its pathology, they all agree in recognizing it as a frequent cause of the death of the fœtus. It is usually found in the chronic form, although Slavjansky describes an acute form which he has frequently found in pregnant women who were suffering from cholera. In all cases abortions resulted and the mothers frequently died. When chronic, they have existed for some time before pregnancy has taken place, as inflammation of the mucous membrane of the uterus. This endometritis may have originated from a passive congestion, as already indicated, but there is no question that latent gonorrhœa is a very frequent starting point. Authors have described three different varieties of endometritis as affecting the integrity of the decidua. This depends upon the point of contemplation. It is probable that these three varieties arise from similar causes and are but different stages of the same inflammatory process. Chronic diffuse endometritis may be considered the mildest type, and here we will describe its pathological peculiarities. It always begins by a destruction and desquamation of the epithelium covering the mucous membrane of the uterus. The underlying surface is then affected. It becomes red and swollen, and connective tissue of varying thickness forms. The utricular glands become involved; so, too, do the cups of Montgomery. At first these cups take on a cystic appearance, but they afterwards atrophy. The whole mucous membrane subsequently becomes thickened and hyperplastic, so that when conception takes place it is absolutely impossible for the fecundated ovum to receive the necessary amount of nourishment for its growth and development. The proliferation of the cells of the mucous membrane is not always so profuse as this, and the alteration may be limited. In such instances it may be possible for an ovum to become attached and to go on developing for a time. Sooner or later, the irritation which the inflammation produces causes uterine contraction and brings about the death and expulsion of the embryo. Still other cases are known where the in-

flammation is of an extremely mild form, and where the nutrition of the ovum has not been sufficiently interfered with, and where the pregnancy has gone on to the full term. In these, the membrane is much thicker than normal, and its structure is considerably firmer than ordinarily. On microscopical examination it can be seen that there has been an attempt at increase of the cell elements of the decidual structure. In all probability there has existed a low inflammatory condition of the uterine mucous membrane prior to the period of conception. A variety of endometritis has been described by various authors as adhesive in its character. It is peculiar in that it usually does not make its appearance until the later months of pregnancy. It is generally limited to the uteroplacental mucous membrane, and should be considered as an affection of the placenta. One of its results is to form a firm adhesion between the placenta and the uterine wall. It may or may not jeopardize the life of the fœtus, but it nearly always complicates delivery. The placenta does not come away spontaneously, and frequently is difficult to remove artificially. Generally, pieces of the placenta will be left adhering to the wall of the uterus, and there form a constant focus of infection. It is in such a condition that the mother experiences pain during movements of the fœtus. The walls of the uterus are tender and painful, and consequently it has received the name of uterine rheumatism by several of the older writers. It is sometimes accompanied by chills, which are probably of a nervous origin. A latent form of syphilis causing a pre-existing chronic endometritis is supposed to be its cause.

Polypoid endometritis has been described by Virchow and others as a special variety of inflammation affecting the decidua. It is now considered similar in ætiology to that of other inflammations of this membrane, but of a more advanced type. The inflammatory process strikes deeper into the uterine surfaces than ordinarily, and, as a consequence, the mucous membrane is much swollen, and thickened to several times its normal degree. This thickening is not, however, uniform. It is much thicker in certain spots than in others, so that there are projecting prominences very similar to polypi standing out from the free surface of the endometrium. It is from this appearance that it derives its name. There is an increase and proliferation of the interstitial mucous membrane and a consequent hypertrophy. So much may this increase develop as to interfere with the nutrition and safety of the fœtus. The change is usually to be found in very young ova, and then it produces material alterations in the villi of the chorion. It is supposed to be due to a latent form of syphilis.

Another variety of inflammation affecting the decidua is that which is known as catarrhal endometritis. It is this form of inflammation which constitutes the hydrorrhœa in the pregnant woman. When fully developed, there is a more or less constant discharge of

transparent fluid from the uterus. Usually the fluid does not make its appearance until the last months of pregnancy, and then it persists in dribbling away at intervals until abortion takes place, although there may be no injurious effects and pregnancy may continue until the full term. Much discussion has taken place as to the source of the fluid and many discordant opinions have been expressed on the subject. The majority of German writers who have investigated the subject are of the opinion that it arises from the cavity of the decidua. They assert that the decidua is a secreting membrane, even while pregnancy is in progress, and that by some irritation or perversion of function the hydrorrhœa is due to a hypersecretion. Others cling to the opinion that the fluid comes from the amniotic cavity and that the decidua has nothing to do with it. Mattei advances the opinion that a sac exists between the chorion and the amnion, and that by some unusual exertion on the part of the mother a perforation takes place through the wall of the decidua and the fluid then burrows down along the uterine wall. Ternier and Budin, in their work on *Midwifery*, admit that it is usually due to an abundant secretion from the glands of the mucous membrane, but that, occasionally, the amniotic sac ruptures high up, so that only a certain amount dribbles away at one time. They give a drawing of a portion of the amnion with a perforation through its centre. It is not usual for hydrorrhœa to complicate pregnancy, and most women thus affected manage to go to the full term of pregnancy. In rare instances the discharge is not the clear, transparent, colorless fluid like that of the liquor amnii, but dark, grumous, and serosanguineous. This is more formidable to the welfare of pregnancy. In such cases the fluid may be too thick to pass away and it lodges between the decidua and wall of the uterus. When composed principally of blood, the clots can be found arranged in layers of different colors and consistency. The term usually given to this condition is that of "carneous mole."

Deciduoma Malignum.—That a malignant condition of the decidua should take place and pass unrecognized for so long a time is somewhat remarkable. So far as we have been able to ascertain, no description of this disease has yet been found in any of our text-books. It is but recently that any attention has been directed to this peculiar condition. Morice Cazin has written upon this subject more lucidly than any other man, and what we know of its ætiology and pathology is mainly due to his investigations. These growths are composed of large giant-cells with a basis of tissue resembling the sarcomatous type, and having no intercellular elements. The cells themselves have no definite arrangement and are quite distinct from those found in epitheliomatous neoplasms. Hæmorrhagic infiltrations are frequently present, and small patches of necrosis are not unusually seen. Against the sarcomatous origin of these growths,

Marchand maintains that they are of a carcinomatous nature and are principally developed from the ovum. His opinion is that they are epithelial and have their beginning in the syncytium and the epithelium of the ectoderm. This simply means that he considers these growths as derived from the serotina. Whatever be their origin, they soon invade surrounding structures, penetrating through into the uterine wall, and may even reach out to the annexa. They distribute their cells somewhat irregularly, and the consequence is that in the more active areas there may be seen superficial zones of necrosis and a breaking down of tissue to such an extent that hæmorrhages are liable to occur. This accounts for the characteristic and intermittent attacks of flooding which are such a prominent and clinical feature of this disease. Lying adjacent to the necrosed portion, the tissues are much firmer for a considerable distance. Secondary nodules of this same protoplasmic material after a time develop throughout the muscular structure of the uterus. It is an exceedingly difficult condition to recognize, and it is very rarely suspected until after labor or abortion. It is much more frequent in comparatively young women. After labor or abortion, sooner or later, intermittent hæmorrhages appear, and they constitute one of the earliest and most prominent symptoms. In a certain proportion of cases a hydatid mole may be discharged, and may be followed by a discharge of foul-smelling, dirty-colored, broken-down material.

When the disease becomes more advanced, general cachexia will supervene. The influence of this disease upon the life of the embryo depends greatly upon its rapidity of advancement. In some instances its progress is quite acute and causes such a disturbance to the nutrition of the fœtus as rapidly to bring about its death and expulsion.

(To be continued.)

EMPHYSEMA OF THE EYELID FROM NASAL CAUSES.

BY BEAMAN DOUGLASS, M. D.,

NEW YORK,

PROFESSOR OF DISEASES OF THE NOSE AND THROAT, POST-GRADUATE MEDICAL SCHOOL.

EMPHYSEMA of the eyelid, or the presence of air in the lid, is a condition that generally interests the eye specialist more than the rhinologist. However, certain cases have come under my observation which have interested me considerably, and I have found from reference to literature that very little has been published on this subject. The subject receives but the shortest notice in small type in the well-known book of Professor Fuchs. It seems to me that this is a condition of some importance, one which causes extreme alarm at the time of its occurrence, and, when it is due to operation, produces more or less apprehension on the part of the operator from the possibility of septic infection of important

organs other than those which are in the field of operation.

I do not wish, in this paper, to deal with the cases of air appearing in the cellular tissue of the upper lid, when they are due purely to eye conditions, nor is it my desire to deal with those cases which may be produced from fracture of the nasal bone or after operation upon the lacrymal duct. Such cases almost always give the history of an accident. Immediately afterward, the nose has been severely blown, generally to remove the blood, and the air, under considerable pressure, is forced through some channel, finally reaching the loose cellular tissue of the lid; the air collects very suddenly, causes pain, and is followed immediately by swelling and the presence of the air tumefaction. It may be so large as to close completely the upper lid over the eyeball.

All these cases must directly or indirectly necessarily receive the air pressure which causes the lesion through the nasal channels.

In the operation upon the lacrymal duct, the knife incises the wall of the duct, and, if the knife is introduced far enough through the duct wall, it enters the cellular tissue surrounding the upper end of the lacrymal duct; particularly the loose cellular tissue in the lid. Given, then, a patient who blows the nose, there is a sudden rise of pressure throughout the nasal chambers; this pressure is felt in the lacrymal duct, particularly if the small valve which lies at the nasal opening of the lacrymal duct has been distended or cut in the operation, and the air is forced through the cut wall into the cellular tissue of the eyelid. If this valve is present and sufficient, it is probable that emphysema of the eyelid could not occur, even if the walls of the lacrymal duct had been incised.

The cases which occur after fracture of the nasal bone are not difficult of explanation. It is necessary only that these fractures shall be compound, and that there shall be a slight rent or tear in the nasal mucous membrane near the seat of the fracture. The patient who blows the nose with this condition present forces the air through the rent in the mucous membrane, through the fractured nasal bone into the loose cellular tissue to the outside of the bone, and thence it is further forced into the upper lid.

The cases which I particularly desire to present for your consideration are those which occur from ethmoidal causes. In order to illustrate what is meant, I will narrate a case:

J. P., aged twenty-three years, came to the Post-Graduate Hospital during the winter of 1899, suffering from double ethmoiditis. One side was operated on without any unusual occurrence. The left side was operated on two weeks subsequently, by the usual method of opening the cells and destroying the cell walls. This was done after a method which will hereafter be described.

The operation was completely successful, without

any accident, and the patient had left the operating chair and was seated some distance away while another operation was in progress. Five or ten minutes after the operation was completed he desired to blow blood from his nostril, and in doing so closed the right nostril completely with a towel, and the left partly—as most patients do who desire to empty the nasal cavity. During the act of blowing he suddenly stopped, shrieked with pain, and put his hand to his eye. In less time than it takes to tell, the entire upper lid was filled with air from the nose, and was so swollen that the lid fell completely over the eyeball and it became impossible for the patient to open his eye. The skin of the eyelid was swollen and tense, the surface of the lid being globular in form instead of being a fairly convex surface. Diagnosis was made of emphysema of the lid from probable fracture of the orbital plate of the ethmoid bone. The patient was placed in bed, ice cloths were applied, together with a gentle massage, and in a few days the condition entirely subsided without sepsis or reaction. Two days after the operation a severe ecchymosis appeared in the inner angle of the upper lid. There was no exophthalmos; neither was any distention or protrusion of conjunctival membrane noticed.

This patient was seen six months afterward, and he has remained entirely cured.

A brief account of another history will serve to illustrate a case which may occur without operation:

A. B. came to the Manhattan Eye and Ear Hospital with a marked emphysema of the right eyelid, which, he stated, came suddenly after a violent attempt to remove secretions from the nostril. The lid was completely ballooned out so that the eye was entirely closed, and there was no emphysema of the lower lid. Examination of the lacrymal duct showed it to be normal in every respect. It would seem, in view of the facts, that the lacrymal duct was normal and that there was no traumatism of the nose, that this case must be one of those in which a pathological opening existed between the ethmoid cells and the bony orbit. This patient has been subsequently seen and the following conditions noted:

The whole of the patient's nose is deformed, being deflected to the left side. The external deformity is very marked. The nasal septum is concavoconvex from before backward, the anterior part being concave, while the posterior part is markedly convex. At the posterior part of the nasal septum, it presses firmly against the right middle turbinate body; but this turbinate body is neither inflamed nor congested. The patient states that the right side of the nose bleeds if he blows the nose too hard, this bleeding being profuse and lasting from ten to fifteen minutes. There is some nasal discharge from both sides, the quantity from each side being equal. An effort was made to find an opening existing between the ethmoid cells and the orbit, but nothing could be demonstrated; and the patient, on blowing the nose as hard as possible, did not produce any emphysema of the lid.

This case is interesting and important because it shows that emphysema of the upper lid can exist from pathological nasal conditions, all other causes of such a condition having been excluded in the diagnosis. It also shows that, when the ethmoid cells are not particularly and actively inflamed, air may escape from the

cells into the orbit during the process of the blowing the nose. It also shows that after this accident has occurred, it is possible for the opening which has been made by blowing the nose to heal spontaneously and completely, so that the accident need not be repeated.

These three deductions are important from a medico-legal standpoint, because this case proves absolutely that such a condition may occur and be entirely recovered from, so that it cannot be again produced, and that the operating surgeon did not cause it.

The next is as follows:

Philip First, aged twenty years, referred to me by Dr. Frank K. Irwin, of New York, was seen the day of the occurrence of the emphysema, and stated that at 9:10 o'clock in the morning of November 20, 1900, he blew his nose while dressing. He ordinarily did this each morning in order to remove the mucus which had collected during the night. This morning he did not blow his nose harder than usual, but he immediately felt as if he had blown something into the left eye, and noticed an immediate swelling of the left lid, the eye becoming entirely closed. The sensation was not that of pain, but rather of pressure. After he had blown the nose in this way, a certain quantity of bloody mucus appeared as he continued the operation of blowing. The patient states that this swelling of the lid has never occurred before. He also states that he never has had any operation upon the nose, except one upon the cartilaginous septum, which was operated on fifteen years ago.

The nasal examination shows, on the left side, a slight thickening in the nasal septum. The cartilaginous septum is partly absent, and its place is taken by cicatricial tissue. The top of the nose is flattened and somewhat sunken, as is frequently seen in patients where there is an absence of cartilaginous septum. The left inferior turbinate is normal; the left middle turbinate lies against the septum, but otherwise is normal. The right side of the nose is normal except for the before-noted condition of the nasal septum. The left eyeball is normal and does not protrude further than the right, but the upper lid is swollen so that the eye is completely closed. When this swelling is touched with the finger it gives forth a sound, and bubbles of air can be seen passing beneath the integument of the lid. The lower lid is normal. At my request, the patient blew the nose rather hard, while I placed my finger over the inner third of the upper eyelid about the point of insertion of the levator palpebrarum muscle. Upon each effort to blow the nose a distinct impulse could be felt transmitted to my finger, which was placed on this emphysematous lid, while upon the opposite lid no such impulse could be felt. After blowing the nose three or four times, the eyelid became extremely tense from the presence of air, and it was noticed that the eyeball, which before occupied a normal position in the orbit, protruded considerably more than the opposite eyeball. The conjunctiva at the inner canthus was pushed forward and was filled with air. In other words, this patient was able to increase the emphysema of the eyelid at will by blowing the nostril, even so far as to cause a protrusion of the conjunctiva and to push the eyeball somewhat forward. This impulse, which can be felt on the eyelid when the nose is blown, is, so far as I know, a new sign, for I do not remember ever reading about such an observation. The fact that the impulse can be felt at the inner third of the eyelid, together with the fact that

the conjunctiva is pushed forward at the inner canthus, indicates the point of greatest pressure, and corroborates the explanation which will be given later, as to how the air escapes into the eyelid. There is no evidence in this case of any ethmoiditis.

This case is important in the following way: It shows absolutely that the cause of emphysema must be in the region of the ethmoid cells, for in this case all other parts could be absolutely excluded as a causative element. It also shows conclusively that it is ordinarily caused by blowing the nose, and that it is not necessary that the nose should be blown harder than usual. It also shows a possibility of its occurrence without traumatism. Should this accident have occurred during an operation upon the ethmoid cells, the surgeon would undoubtedly have felt that it was his fault. Yet in no way could the operator be blamed for the occurrence had he been operating upon the nose of this patient at the time emphysema appeared.

Another patient coming more recently under my observation developed an emphysema of the upper lid during an operation upon the ethmoid cells. The history of the case runs as follows:

This patient, having an eye which was perfectly normal and hypertrophied lesions in the nose, submitted to operation for the removal of polypoid hypertrophy in the middle turbinate region. During the operation for removing the small polyps, pus was noticed issuing from the ethmoid cells, and the patient was sent to the transilluminating room for the purpose of transillumination, which showed that the antrum was involved and the frontal sinus was normal. The antrum was washed out and a small quantity of pus obtained from the left side. The following day the ethmoid cells were opened, without removing the middle turbinate body, which was used as a guide in introducing the cutting forceps into the ethmoid cells. With this turbinate as a guide, the alligator cutting forceps opened the anterior ethmoid cells. After this was done they were thoroughly curetted by means of the Hajek curette. Before the operation was completed the patient was ordered to blow her nose in order to remove clots of blood. This she had previously been ordered to do with good results. But this time, so soon as an attempt was made to blow the nose the patient cried out with pain and put her hand over her left eye. At once it was noticed that the eyelid was emphysematous without any extravasation of blood. The operation was completed and the patient was placed in bed, pressure and cold were applied, and in twenty-four hours the emphysema had entirely disappeared. The subsequent history is without interest, except to record a cure of the ethmoid and antrum disease.

As is easily seen from the cases here cited, this condition is not one of grave danger, and, in fact, is one of hardly any importance, except for the possibility of a further wound accident occurring. It is, of course, alarming to the patient when the air rushes into the orbit and leaves the impression on the part of the patient that a condition has arisen in the operation which is not at all desirable. This conjecture is probably made by the patient as often from the surprised and annoyed expression of the operating surgeon's face as from the

slight distress experienced from the emphysema. It must be remembered, however, that, while in the cases cited, no septic conditions have followed the entrance of air into the orbit, it is, nevertheless, possible for bacteria and putrid material to be carried along with the air at the time of its entrance, and there, in the upper part of the orbit, to set up a septic cellulitis of the eyeball and upper lid, eventually forming an abscess in the orbit, with the production of a severe exophthalmos and possible destruction of the eye. One such case I have seen in consultation; but it has never been my misfortune to have any septic condition follow this occurrence. Just at this point, there are three questions which may be asked with interest and answered with satisfaction:

(1) Is the condition which causes emphysema a wound accident, or may it result from pathological conditions occurring in the nose before operation?

(2) Is the surgeon at fault for this condition?

(3) Why does air enter the upper lid instead of the lower? How can we prevent such an occurrence?

Without a doubt, emphysema of the eyelid may occur from any wound of the lacrymal duct, such as the Bowman operation. It is also possible that it may occur when, from disease, the wall of the lacrymal duct has become weakened. But the question, whether emphysema is a wound accident which may occur in the lacrymal duct during an operation for ethmoiditis, is one about which some doubt may be expressed. It is possible to believe that the operator when working upon the ethmoid cells, particularly on the most forward ones, which generally lie very near the lacrymal bone, may perforate through the thin plate of the lacrymal bone, and in this way wound the upper part of the lacrymal duct while doing the ethmoid operation. The lacrymal bone at this region is particularly thin and is located just in front of the hiatus semilunaris and just at the outside of the processus uncinatus. As these are in the neighborhood of the parts removed in the ethmoidal operation, it is possible for the instrument to wound the lacrymal duct and the lacrymal bone in this ethmoidal operation. Under ordinary circumstances, when a wound of the lacrymal duct has been produced in the lower part of the duct, an emphysema of the *lower* rather than of the upper eyelid is more likely to occur. But when one is operating on the higher parts in the region of the ethmoid cells, the higher parts of the lacrymal duct alone can be wounded; and under these circumstances one can believe that, upon blowing the nose, the air rushing from the nose through the wounded lacrymal duct can produce emphysema of the upper eyelid. This must be a very rare condition. Any emphysema of the upper lid occurring as a wound accident is oftener, and, indeed, almost always, from direct perforation of the lamina papyracea of the ethmoid bone, which also forms part of the orbital wall. In this wound accident the conditions are slightly different

from those obtaining when the upper part of the lacrymal duct is wounded, for during the ethmoid operation the instrument simply fractures part of the orbital wall, and wounds and tears as well the mucous membrane lining the ethmoid cells. This allows a direct communication of air between the nose and the orbit. This perforation through the thin layer of the orbit wall is a result for which a surgeon can in no wise be responsible. It certainly is liable to happen where there are very narrow ethmoid cells. That is, the space occupied by the cells between the outer nasal wall and the inner orbital wall varies so greatly that while in some instances it is so wide that a perforation is not easily possible, in other instances it may be very narrow, so that very little ethmoidal space exists between the nares and the orbit. There is no way by which narrow ethmoid cells can be distinguished by any examination, either external or internal, from those which are more capacious. The surgeon has to bear in mind the possible existence of narrow cells, and to work as far from the orbital plate as possible.

Again, any anatomical variation may make it possible for the surgeon to perforate. This is not due to carelessness on his part, for, in many instances, the anterior ethmoid cells are not developed as well forward as would be considered normal, being either very small or else the anterior cells are practically undeveloped. In such instances it is very easy for the surgeon to perforate the orbit in the absence of these cells.

No blame can be attached to the surgeon who exhibits ordinary care in the operation on the ethmoid cells when perforation occurs, for it is possible that a pathological condition may in itself form a communication between the eye and the ethmoid cells, and that this pre-existing opening between the orbit and the ethmoid cells allows of no entrance of air into the orbit until the surgeon operating on the ethmoid cells opens a cell which communicates pathologically with the orbit. This pathological communication may be explained by an absorption of a portion of the bone from the lamina papyracea, so that the linings of the orbit and the ethmoid cells lie together. It will be seen, then, so soon as the instrument enters the cell, the air follows it, and communication is established between the orbit and the nose without the surgeon having fractured or perforated, or in any way having wounded, the orbital plate. The possibility of this pathological condition should prevent our ever severely criticising the surgeon who finds an emphysema developed after his ethmoid operation.

The answer to the second question, as to whether the surgeon is at fault for this emphysema, has practically already been answered in the foregoing, and may be repeated with an emphatic "No." For the reasons given above, the surgeon cannot be made responsible for this wound accident.

It is interesting to explain why the air in these conditions enters the upper lid instead of the lower. In

most of the traumatism of the lacrymal duct the air enters the lower lid, but in all of the cases of traumatism of the ethmoid perforating the orbit which I have seen, the air has always been in the upper lid. This is probably explained by the fact that the wall of the orbit is perforated, as a rule, pretty near the middle, and that the air at once enters the space between the orbital periosteum and the first fascia of the eyeball. It seems that there is a fascia which extends from one side of the orbit to the other, separating the extrinsic muscles of the eyeball from the intrinsic. In other words, the muscle which raises the upper eyelid lies above this fascia and runs from the posterior part of the orbit forward to the tarsal cartilage of the upper lid. The fascia lies below it, separating it from the muscles which move the eyeball, and it is into this layer above the intrinsic muscles that the air from the ethmoid cells escapes. The air makes its way between the bony orbit and this fascia forward and backward, but finds less resistance forward than backward. Therefore, it infiltrates the loose cellular tissue of the upper lid and produces an immediate condition of emphysema. Such an occurrence can be partially guarded against by observing the following rules in operating:

(1) As much as possible, avoid the use of the curette, for it is the curette, I believe, which is responsible for much of the traumatism occurring to the lamina papyracea. Much better work can be done by the use of the alligator forceps, or some kind of cutting forceps having a small, blunt edge, which is less apt to perforate, and which will, with equal success, drain pus or remove polyps, as well as the mucous membrane lining the ethmoid cells. This forceps is very much more satisfactory than the curette in cutting away the thin layers of bone which form the walls of the ethmoid cells.

(2) Another rule is never to amputate any part of the middle turbinate, as it forms a very important guide along which an operation may be carried out. When it is remembered that the upper part of the middle turbinate body forms the inner wall of the ethmoid cells, it can readily be appreciated that by working carefully along the outer side of the middle turbinate—that is, the side away from the sæptum—the instrument must in each instance perforate the ethmoid cells, first, those which are anterior, and later, the posterior cells. In this way it is possible to open the ethmoid cells in the immediate neighborhood of the middle turbinated body without working too near the orbit. This valuable guide will often prevent our entering either the orbit or the brain cavity. If, subsequently, it becomes necessary to remove this turbinate, it may be taken away after the ethmoid operation.

While this condition, so far as my personal experience is concerned, has never been of any moment or seriousness, it can readily be appreciated that it is a condition from which grave danger may arise. Abscess,

destruction of the eye, and possible meningitis may arise from septic conditions in operations carelessly done on the ethmoid bone. It is with a view to avoid these possible complications that our attention has been directed to this subject to-night.

Correspondence.

LETTER FROM TORONTO.

The Need of Infectious Diseases Hospitals in Montreal. —A Proposed Sanatorium for Consumptives in Nova Scotia.—The Winnipeg General Hospital.—An Increased Birth Rate in Ontario.—Lodge Practice in British Columbia.—The Medical Alliance of America.

TORONTO, March 9, 1901.

THE hospitals for contagious diseases for which Montreal has been struggling for a long time now seem to be as far off as they were two years ago. The present civic hospital is totally inadequate for the purpose it serves, and has been frequently condemned by prominent medical men of the city, as well as by numerous private and influential citizens. There are two propositions now before the city council—one for a single establishment under direct civic control, and the other to establish two hospitals under the respective control of the Hôtel Dieu and the Royal Victoria Hospital. Apparently the reason for not proceeding with the erection of the institution lies in the fact that the demands of the French and the English sections of the community must be adjusted satisfactorily. There is urgent need for a new hospital, as the death rate of the present civic hospital is enormous, and this excessive death rate is manifestly due to the defects of the present building. Small-pox is hovering at the present time around the outskirts of the city, and the city has absolutely no place in which to put a patient afflicted with this disease. Montreal appears to have a council which is not up to the times, so far as hygienic requirements are concerned, as when the provincial secretary of the board of health notified them that there were six cases of small-pox within a few miles of the city, the council showed their idea of the urgency of the matter by ordering the communication to lie on the table for a week.

A sanatorium for consumptives for the Province of Nova Scotia has been in contemplation for some little time, and the committee appointed by the government to look into the matter and submit recommendations has, through Premier Murray, laid its report before the Legislative Assembly, now in session. As to the location, the committee recommends that either Dutch Village, near Halifax, or a place on the shore of Bedford Basin, near the village of Bedford, be selected; that the congregate plan be adopted for a small number of patients, as they deem it more suitable; the accommoda-

tion to provide for twenty patients, with a competent and specially trained female nurse as lady superintendent, no resident medical superintendent, but regular stated visits to be made by two qualified medical men every week. The committee expressed the opinion that the treatment of consumption should be carried on in juxtaposition to centres of population, and further recommended that the sanatorial act passed at the last session of the legislature be amended to the extent that it might provide for municipalities receiving aid from the government for the purpose of establishing sanatoria. Dr. Reid, the secretary of the Provincial Board of Health, indorses the recommendations, with the exception of that relating to a resident medical officer and the site recommended on the Atlantic seaboard, which he considers unsuitable for the purposes of a sanatorium. Nova Scotia is likely to proceed at once in pursuing a systematic course with regard to the establishment of sanatoria.

The Winnipeg General Hospital board of governors met in annual meeting on the afternoon of February 28th. The report of the medical superintendent showed that the number of patients treated in the hospital during the past year amounted to 2,649, and in the outdoor department there were 1,435 consultations. Of the indoor patients, 1,684 came from the city of Winnipeg, 785 from other places in the Province of Manitoba, 150 from other provinces in the Dominion, and 30 from the United States. The financial report showed that there was a deficit of \$4,510.50, which was accounted for by the fact of the outbreak of small-pox in the institution during the early part of the year. Reference was made in the report to the death of Nurse Lynch, who contracted the disease while in the discharge of her duties. The nursing staff of this institution now consists of a lady superintendent, five head nurses, one district nurse, and fifty pupil nurses. During the year 223 applications were received; of these applicants, twenty-three were accepted on probation and sixteen as pupils of the school.

An increase in the birth rate of the Province of Ontario is apparent from the report of the registrar-general. This is encouraging, as for the past years there has been reported an alarming falling off in this department of vital statistics. Several young fathers have been recently prosecuted for neglecting to register under the provisions of the act, and this has probably had a good deal to do with the increase. The following shows the births for the past three years, 1898, 1899, and 1900, in the Province, respectively: 46,599, 44,705, and 46,019, the increase over last year being 1,314. Of marriages, there were in the same years: 15,375, 16,514, and 17,123, being an increase of 609. Of deaths, there were: 26,370, 28,607, and 29,594, an increase of 987. The secretary of the Ontario board of health, Dr. P. H. Bryce, estimates that the birth rate last year was 19.9 per 1,000, compared with 19.4 in 1899 and 20.4 in 1898. Dr. Bryce

compares these rates with that of England, which was 29.4 in 1898; with Scotland, 30.8; with Ireland, 23.2; with Connecticut, 24.4; with Buffalo, 30.; with Baltimore, 32; with New York city, 22.11; and with St. Paul, 16.4. He considers that the lower rate prevails in Ontario on account of the rural population.

Lodge practice in British Columbia received a "jolt" a little more than a year ago, when the Medical Society of Victoria declared that they would have nothing more to do with that stultifying department of the practice of medicine. For more than a year the special committee appointed by the fraternalists to fight the doctors has been working, and frequent have been the endeavors to induce Ontario practitioners to come to British Columbia and assume the lodge practice, but the examinations of the Medical Council of the Province proved a bar to their progress; and then there has not been anywhere apparent on the part of the eastern practitioners a "rush" to this new Eldorado in the medical world on the Pacific coast. One would gather, however, from the very latest reports from British Columbia that the doctors were on the "cave," and that the fraternalists were about to "win out" in the long fight. During the past summer the committee has not been idle. Petitions have been circulating broadcast throughout the entire Province; thousands have signed these, persons connected with societies, and they have been duly presented to the legislature of the Province, now in session, praying that the medical act be so amended as to permit of practitioners from the older Provinces, as well as from England, entering upon the practice of medicine in British Columbia without the customary examinations, provided they are already qualified in the other Provinces and in England. Against such odds as this, that faithful little band in Victoria will probably have to surrender; and another abortive attempt will have to be registered where an endeavor has been made to throw off this galling yoke. It is to be sincerely hoped that the profession in Victoria may still stand out for their rights and their honor.

The Toronto Clinical Society, at its regular meeting on the evening of March 6th, issued an unfavorable pronouncement upon the Medical Alliance of America, with headquarters at Montreal, and advised practitioners to have nothing to do with the alliance whatever. This is an organization which was incorporated by the Dominion Parliament during the session of 1899-1901, and at once began exploiting the profession in the city of Montreal and elsewhere in the eastern Provinces. Last fall it appeared in Toronto, and without due and proper examination of its prospectus several of the city physicians were induced to become members of the alliance. The doctor and his patient, or some other doctor's patient, must become members of this alliance; then the company agrees to pay the doctor "not more than \$1 per office consultation and not more than \$1.50 per house visit." It purposes doing away with "bad debts" for the doctor, and assuring to him his pay for the work he performs. It

further purports to do away with the lodge practice business; but its methods are not thought well of by the profession in Toronto; hence the action of the Clinical Society.

Therapeutical Notes.

The Treatment of Grippe.—The editor of the *New Orleans Medical and Surgical Journal* gives the following in the issue of that journal for February:

Mild Form.—However light the attack, the patient should remain indoors for several days. Diet light and nutritious, with cooling drinks (lemonade, apollinaris, etc.). A gentle movement of the bowels daily. Dover's powder, ten grains, monobromide of camphor, one grain and a half, if there be much headache.

Quinine sulphate in five-grain doses every four or five hours.

Strychnine sulphate, one thirtieth of a grain, three times daily.

Medium Form.—Patients should go to bed, and remain there until convalescence is well advanced. Diet, liquid in character, and given frequently in small quantities. Whisky or brandy in two-drachm doses, well diluted, several times during the twenty-four hours. Cold sponge baths if the temperature is above 102° F. For neuralgia, Dover's powder and monobromide of camphor. Quinine sulphate, salicylic acid, or salicylate of sodium, when the temperature range is high. Caffeine citrate, two grains; phenacetine, two grains, to control insomnia. For sleeplessness, trional, sulphonal, opium. Steam inhalations (formic aldehyde, benzoin, etc.), or inunctions of animal fats over the forehead and bridge of the nose, if coryza is troublesome.

The following is useful to mitigate cough:

℞ Heroine 1½ grains;
Chloride of ammonium 2 drachms;
Syrup of tar 2 ounces;
Syrup of tolu 2 "
Syrup of prunus virginiana, to
make 5 "

M. Sig.—Two teaspoonfuls every three or four hours.

Codeine sulphate, 3 grains, could be used instead of the heroine, if desired. Turpentine stupes or mustard plasters to the chest. Strychnine sulphate, one thirtieth of a grain, every three or four hours, day and night.

Severe Form.—Quinine sulphate in full doses, strychnine sulphate, digitalis hypodermically, bold stimulation. The various complications must be treated as they arise.

Tincture of Iodine in Infantile Diarrhœa.—M. Cattaneo (*Semaine médicale; Revue mensuelle des maladies de l'enfance*, March) has obtained excellent results in infantile diarrhœa from the treatment by tincture of iodine so much lauded by M. Grosch for infectious gastro-enteritis and typhoid fever.

℞ Tincture of iodine from 10 to 15 drops;
Distilled water 2,250 minims;
Syrup 300 "

M. A coffeespoonful every two hours.

Under this treatment, in cases of acute gastro-intestinal catarrh of nurslings, associated with a hydric diet and lavages of the intestines, vomiting is said to cease immediately and the fever to disappear at the end of two days.

For Chronic Ulcer of the Stomach.—*Ἰατρικὴ Πρόοδος* for January cites the following from *Therapeutische Blätter*:

℞ Chloroform 18 drops;
Subnitrate of bismuth 45 grains;
Water 5 ounces.
M. Half a tablespoonful every hour.

For the Intractable Cough of Phthisis—(A Correction).—Dr. W. C. Deming, of Westchester, has called our attention to an obvious typographical blunder in the formula published under this title in our issue for March 9th, the error consisting of the omission of a decimal point after the figures 1 and 3 in the first two quantities designated. Owing to the excess of solids ordered, it would manifestly be impossible to dispense the mixture according to the formula as originally printed, a fact which any dispenser would have observed even if the error should have been overlooked by the physician.

An Ointment for Chronic Blepharitis.—*Ἰατρικὴ Πρόοδος* for January ascribes the following to Panas:

℞ Binoxide of mercury 1½ grains;
Lead water 10 drops;
Petrolatum 5 drachms.

M.

To be applied night and morning to the free edges of the lids.

For Tuberculous Laryngitis.—Dr. W. Freudenthal (*Journal of the American Medical Association*, March 16th) cleanses the larynx with some indifferent spray, or swabs it with cotton. A cleansing powder of from three to six grains of saccharated suprarenal gland is then insufflated into the larynx, on to the ulcerations, which exsanguinates the larynx and causes some local anæsthesia, when the following emulsion is applied locally by injecting *slowly* with a laryngeal syringe:

℞ Menthol 1 part;
Oil of sweet almonds 30 parts;
Yolk of egg 25 "
Orthoform 12 "
Distilled water to 100 "

M.

As the toleration of the patient permits, the menthol is increased to 5, 10, or even 15, per cent.

For Neuropathic Alopecia.—*Ἰατρικὴ Πρόοδος* for January cites the following on the authority of Brocq:

Frictions are made with the following mixture:
℞ Glacial acetic acid 12 minims;
Tincture of cantharides 1 drachm;
Spirit of rosemary 1 "
Tincture of couch grass 2 drachms;
Spirit of camphor 2 "

M.

Then Dupuytren's ointment is to be applied. [This is made by macerating a drachm of cantharides in a fluid ounce of alcohol and incorporating one part of the tincture thus formed with nine parts of lard.]

The foregoing liniment may be replaced by the following:

℞ Ammonia water 24 minims;
Tincture of pellitory, }
Tincture of jaborandi, } of each 1 drachm;
Oil of turpentine, }
Alcohol 6 drachms.

M.

NEW YORK, SATURDAY, MARCH 23, 1901.

THE PLAGUE IN CALIFORNIA.

IN our issue for March 2d we remarked upon the futility of the policy pursued by the State government of California in denying that there had been any cases of the Oriental plague in San Francisco and in seeking to discredit and obstruct Dr. Kinyoun and, through him, the United States Marine-Hospital Service in their efforts to avert a serious visitation of the plague. We were glad to be able to cite the manly and enlightened course of the *Occidental Medical Times* and the Sacramento *Evening Bee* in protesting against the State government's narrow-minded policy in the matter. We are glad now to be able to say, on the authority of the *Bee*, that the governor and his coadjutors seem to have been brought to realize at last that they cannot expect the rest of the country to accept their unreasonable and unsupported statements in opposition to the deliberate and unbiased findings of Dr. Kinyoun and his associates. Although at the time of our writing the details of the plan to be pursued in stamping out the infection do not seem to have been settled upon, it may be stated that they will conform as closely as possible to Dr. Kinyoun's original scheme, and that the State and municipal governments will cooperate with the efforts of the Marine-Hospital Service.

This is not a journal of politics; consequently we cannot take cognizance of the allegations that have been freely made of unworthy motives having prompted Dr. Kinyoun and his associates to insist upon the actual occurrence of the disease in Chinatown. With alleged railway rivalries and with dreams of the future supremacy of Seattle in the Oriental carrying trade as factors in the deplorable disagreement that for many months has existed between California and the national quarantine service we have nothing to do, and we mention them now

only to reiterate our conviction that in this whole unsavory dispute the Marine-Hospital Service has had nothing in view but the real welfare of San Francisco, California, and the entire country. We do not like to hear of quarantine discrimination against San Francisco, for we believe there is no occasion for it; we are convinced, however, that the surest way of preventing it lies, not in blind denial of the obvious truth, but in dealing truthfully and manfully with the facts as they are. We are confident that short work will now be made of the danger of a serious prevalence of the plague in San Francisco and that the heartburnings that have been raised by the controversy will speedily be allayed and forgotten.

THE HYGIENE OF THE THEATRE.

OUR attention is called anew to this topic by an editorial article which appeared in the *Gazette médicale de Paris* for January 19th, presumably written by Dr. Marcel Baudouin, whose efforts in behalf of public hygiene are never-failing and whose versatility in bringing medical science to the aid of humanity is known and appreciated all over the world. It seems that in Paris there is a sort of organization of those medical men who have a more or less close connection with the theatres, the *Société des médecins de théâtre*, the organ of which is the *Paris-Théâtre médical*. M. Baudouin assures us that he is himself very well informed as to theatrical matters; we may therefore attach great importance to whatever he has to say concerning them. The society has to do, not only with the care of the stage force, but also with that of individuals of the audience who may be injured or taken ill. They are agitating for greater facilities for the performance of their duties. For example, they are demanding that in every place of public amusement, such as a theatre, a concert hall, or a circus, there shall be a "medical box" (*loge médicale*), that is to say, a space reserved for sick and injured actors and spectators, one large enough to admit of the free movement of two persons in caring for a patient. This space should have a window by which it may readily be aired, and it should be furnished with a sofa, washing facilities, antiseptics, and such medicinal preparations and surgical appliances as are likely to be needed in emergencies, including "une chaise percée."

But such requisites as those thus far mentioned are not the ones of paramount importance in the hygiene of the theatre; what is of the utmost urgency is the curtailment of the theatre's power for harm to the auditors'

health. Chief among the agencies for mitigating the unwholesomeness of the theatre—and this is not overlooked by our French colleagues—is the ridding of the auditorium of its stagnant, germ-laden atmosphere. Inclosed places of public resort must in the very nature of things be laden with a higher percentage of micro-organisms than is to be found in the open air or even in occupied dwellings, and in all probability more of those micro-organisms are pathogenic. Even churches, most of which are occupied but for a small portion of each week, are to be avoided by persons known to be susceptible to tuberculous disease, for they are seldom efficiently aired, save perhaps during the height of summer, a season in which many city churches are disused altogether. How much richer in pathogenic germs must the great majority of theatres be as those institutions are at present constructed and managed! In many of them a very large proportion of the space devoted to the stage and to the auditorium, and in some of them the whole of that space, is never subjected to direct sunlight or even to the ordinary diffused sunlight which we all demand in the rooms of our dwellings. If their floors are ever properly cleansed, it must be at rare intervals. In short, they are ideal devices for the impounding of the germs of disease.

While we freely concede that the theatrical people themselves have done much within the last few years in the way of mitigating the noisomeness of the theatres, notably by improved ventilation and by the substitution of seats of polished wood for the plush-covered cushions of a few years back, we must, nevertheless, insist that the hygiene of the theatre calls pressingly for earnest consideration and radical action at the hands of our sanitary officials, quite as urgently, indeed, as the public conveyances.

THE LAXATIVE ACTION OF APOCODEINE.

APOCODEINE, an artificial alkaloid obtained by treating codeine with zinc chloride, has, according to Flückiger and Hanbury, the formula $C_{18}H_{19}NO_2$. M. Raviart and M. Bertin (*Echo médical du Nord*, December 2d; *Gazette hebdomadaire de médecine et de chirurgie*, February 3d) have been studying the therapeutical properties of its hydrochloride, which were studied several years ago by Guinard, whose *Contribution à l'étude physiologique de l'apocodéine* was published in 1893, and by Toy (*Journal de médecine de Bordeaux*, 1895, p. 442). Both these authors' observations are summarized by Raviart and Bertin. Apocodine has generally been re-

garded as very similar to codeine in its therapeutical properties, and that still seems to be true in respect to its calmative action. It appears to be one of the best of hypnotics, inducing sleep closely resembling normal slumber, never giving rise to nausea or any other unpleasant accompaniment of the awakening, and, if used in moderate doses, quite free from danger.

Its laxative action seems to have been first noted by Toy, and has now been particularly studied by Raviart and Bertin. They found that in twenty-five out of thirty-four cases of constipation proceeding from various causes, a single dose produced an evacuation, sometimes two, and sometimes three. The drug seems to act by increasing all the digestive secretions. For subcutaneous use, the only way in which it seems to have been employed, the usual dose is two cubic centimetres (about thirty minims) of a one-per-cent. solution, which amount is ordinarily sufficient to act upon the bowels, but not large enough to produce more than a very slight hypnotic effect. Raviart and Bertin conclude that apocodeine hydrochloride is always applicable as a remedy for transitory constipation, and often for the habitual affection, without fear of the slightest accident. In almost all cases its action is sure and sufficiently prompt.

CHARITY BEGINS AT HOME.

WE learn from the *Lancet* for February 23d that a judge in the English Court of King's Bench, commenting on the fact that a medical witness had claimed and received a fee of twenty guineas before he would attend to give evidence in a private suit, stated that "it was very hard a plaintiff should be compelled to pay such a sum in order to get his case proved"; and when the witness replied that "he did not wish to come," the judge retorted, "We must have justice, you know." To the witness's further suggestion that there were many young men who would have been glad to come for a smaller fee, the judge said "he would not argue the question, but that it was very hard that a man should have to pay in this way a sum which he could not possibly recover from the defendant."

Such a position is, as the *Lancet* says, as absurd as "to expect that, in order to facilitate the administration of justice, leaders of the bar should forego the high fees which they are accustomed, very properly, to charge."

The absurd *obiter dicta* which occasionally escape the lips of judges in regard to physicians, as, for instance, in the cases commented on in our issues for February 9th and March 9th, seem to indicate a fixed delusion that a physician is a piece of property parcelled out into "whole and undivided parts," as between the several proprietors of which, questions of right and duty

may arise, but who themselves have no rights individually or collectively. It is so easy—and so inexpensive—to be a vicarious philanthropist!

THE DIVISION OF FEES.

DR. ROBERT T. MORRIS writes to the *American Journal of Surgery and Gynecology* for February to comment on the statement of a surgeon "that he will divide the fee with any physician who sends surgical cases to him, and he believes that no wrong will be done to the physician, to the patient, or to himself." As Dr. Morris says, "it all turns on the division of the fee without the patient's knowledge." The physician must needs give his services in preparation for, and after attendance on, the patient, and deserves to be recompensed therefor. If it is made clear to the patient that this just claim of the attending physician is to be provided for by a stated proportion of the lump sum charged for the operation, and agreed upon between the physician and surgeon, it would seem, as Dr. Morris says, to be "an honorable transaction and in keeping with the best interests of a respected profession"; and, of course, the larger the portion of the fee assigned by the surgeon to the physician, the more likely it is to enhance the patient's respect for his regular medical attendant. But if the division is made as the result of a compact between the doctors unknown to the patient, there can be no doubt of the impropriety of such a transaction, which amounts virtually to a selling of the operation, and at least opens the way for preferring the pecuniary advantages of the physician to the interests of the patient. We are glad to see that the editor of the *American Journal of Surgery and Gynecology* has given his adhesion, in an editorial comment, to this statement of the case, which he considers "the solution of this much-discussed problem." It will be remembered that the Chicago Medical Society, as reported in an issue for February 23d, recently condemned the "dichotomy" practice as "a subterfuge."

EXTIRPATION OF THE CLITORIS FOR INCONTINENCE OF URINE.

A CURIOUS case is cited in the *Gazette hebdomadaire de médecine et de chirurgie* for February 3d from the *Archives médicales d'Angers*, 1900, p. 232. A young woman, twenty-eight years of age, was taken suddenly in August, 1899, with inability to retain her urine, which, from that time on, for a period of four or five months, was passed involuntarily, in small quantities of from twenty to thirty grammes, day and night, awake or asleep, and even when the subject was under morphine. Treatment availed nothing and the unfortunate patient was driven to absolute seclusion. Finally, examination elicited the fact that the clitoris was constantly in a state of erection; and the author, Dr. Tesson, remembering the common innervation of that

organ and the bladder, thought that possibly the one erethism depended on the other. He therefore entirely removed the clitoris, with the result that the incontinence at once and permanently disappeared. Information is lacking on the point as to whether the erethism was dependent upon sexual irritation, mental or physical. Did the old saw *casta raro mingit* apply in this case? Some indication is desirable before an epidemic of clitoridectomies for enuresis sets in.

A STRIKE AMONG DOCTORS.

THE *Indian Lancet* for February 11th learns from a Vienna correspondent that, at Cracow, a strike has occurred among the doctors consequent upon an attempted introduction of a legal tariff of fees by the legal authorities. All the *modus operandi* of trades-union measures seem to have been employed, including even the refusal of hospital authorities to treat a child fearfully mangled by a tramcar. We can scarcely credit this statement; for while it is undoubtedly right and proper that physicians should stand by one another in protecting those common rights which there is such a disposition in the public to trample upon, even in the strongest personal contention urgency of life and death must ever be neutral, as even civilized warfare now universally allows and enforces. As for an alleged threat that if they were driven to desperation the doctors would wreak a fearful vengeance by letting loose the germs of bubonic plague and other dread diseases in the town, that probably originated, if it has any foundation in fact at all, in the mischievous, but wofully reprehensible, "chaff" of some irresponsible medical student.

THE RIGHT TO WILL ONE'S BODY FOR SCIENTIFIC INVESTIGATION.

THE Supreme Court of California, in the case of *Enos versus Snyder*, has laid down a ruling the results of which appear to us to be very regrettable from a scientific point of view. It has decided, in a contest between next of kin, on the one hand, and claimants under a will, on the other hand, for the possession of a corpse, that a man cannot by will dispose of that which, after his death, will be his corpse. The custody of the corpse and the right of burial belong to the next of kin in preference to the administrator. This view is based on the fact that the general English and American legal authorities establish the rule that, in the absence of statutory provisions, there is no property in a dead body. If this ruling is correct, the sooner statutory provisions are obtained enabling a man who feels that a great benefit to humanity will accrue, through increase of medical knowledge, by the continuance *post mortem* of an investigation into his case, or that new light may be shed upon anthropological, psychological, or other scientific problems, to authorize by will such use of his corpse, the better. We commend this subject to the consideration of the Medico-legal Society.

News Items.

Society Meetings for the Coming Week:

MONDAY, *March 25th*: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, *March 26th*: New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, *March 27th*: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society.

THURSDAY, *March 28th*: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopedic Society; Brooklyn Pathological Society; Brooklyn Society of Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera and plague were reported to the surgeon-general during the week ending March 16, 1901:

Smallpox—United States.

Mobile, Alabama.....	Mar. 2-9.....	1 death.
Los Angeles, California.....	Feb. 24-Mar. 2.....	5 cases.
Oakland, California.....	Feb. 24-Mar. 2.....	1 case.
Sacramento, California.....	Feb. 24-Mar. 2.....	1 case.
Chicago, Illinois.....	Mar. 2-9.....	7 cases.
Evansville, Indiana.....	Feb. 24-Mar. 9.....	2 cases.
Wichita, Kansas.....	Mar. 2-9.....	23 cases.
Lexington, Kentucky.....	Mar. 2-9.....	1 case.
New Orleans, Louisiana.....	Mar. 2-9.....	14 cases.
Lowell, Massachusetts.....	Mar. 2-9.....	1 case.
Somerville, Massachusetts.....	Mar. 2-9.....	1 case.
Detroit, Michigan.....	Mar. 2-9.....	1 case.
Grand Rapids, Michigan.....	Mar. 2-9.....	1 case.
Minneapolis, Minnesota.....	Feb. 24-Mar. 2.....	4 cases.
Winona, Minnesota.....	Mar. 2-9.....	2 cases.
Manchester, New Hampshire.....	Mar. 2-9.....	21 cases.
New York, New York.....	Mar. 2-9.....	54 cases.
Cincinnati, Ohio.....	Mar. 2-9.....	2 cases.
Cleveland, Ohio.....	Mar. 2-9.....	52 cases.
Portland, Oregon.....	Feb. 1-28.....	2 cases.
Erie, Pennsylvania.....	Mar. 2-9.....	2 cases.
Philadelphia, Pennsylvania.....	Mar. 2-9.....	1 case.
Steelton, Pennsylvania.....	Mar. 2-9.....	1 case.
Jackson, Tennessee.....	Jan. 1-31.....	20 cases.
Memphis, Tennessee.....	Mar. 2-9.....	10 cases.
Nashville, Tennessee.....	Mar. 2-9.....	11 cases.
San Antonio, Tennessee.....	Feb. 1-28.....	16 cases.
Ogden, Utah.....	Mar. 2-9.....	18 cases.
Tacoma, Washington.....	Feb. 25.....	6 cases.
Huntington, West Virginia.....	Mar. 2-9.....	11 cases.
Wheeling, West Virginia.....	Feb. 24-Mar. 9.....	4 cases.
Milwaukee, Wisconsin.....	Mar. 2-9.....	2 cases.

Smallpox—Foreign and Insular.

Prague, Austria.....	Feb. 9-23.....	14 cases.
Vienna, Austria.....	Feb. 16-23.....	1 death.
Antwerp, Belgium.....	Feb. 9-23.....	2 cases.
Sudbury, Ontario, Canada.....	Feb. 22.....	Prevalent.
Ceylon.....	Jan. 26-Feb. 2.....	1 case.
Cairo, Egypt.....	Jan. 28-Feb. 4.....	2 cases.
London, England.....	Feb. 16-23.....	1 case.
Newcastle-on-Tyne, England.....	Feb. 16-23.....	1 case.
Dundee, Scotland.....	Feb. 16-23.....	2 cases.
Edinburgh, Scotland.....	Feb. 16-23.....	1 case.
Glasgow, Scotland.....	Feb. 22-Mar. 1.....	13 deaths.
Bombay, India.....	Jan. 29-Feb. 12.....	6 deaths.
Calcutta, India.....	Jan. 26-Feb. 9.....	235 deaths.
Karachi, India.....	Jan. 27-Feb. 10.....	15 cases.
Madras, India.....	Jan. 26-Feb. 8.....	7 deaths.
Naples, Italy.....	Feb. 20.....	8 deaths.
Malta.....	Feb. 16-28.....	Present.
Progreso, Yucatan, Mexico.....	Feb. 19-28.....	16 cases.
Manila, Philippine Islands.....	Jan. 5-19.....	4 cases.
Moscow, Russia.....	Feb. 2-16.....	10 cases.
Odessa, Russia.....	Feb. 8-23.....	26 cases.
St. Petersburg, Russia.....	Feb. 8-16.....	7 cases.
Warsaw, Russia.....	Feb. 8-16.....	6 deaths.

Yellow Fever.

Honda, Colombia.....	Jan. 7.....	Epidemic.
Guaduas, Colombia.....	Jan. 7.....	Epidemic.
Cienfuegos, Cuba.....	Mar. 4.....	1 death.
Havana, Cuba.....	Feb. 25-Mar. 4.....	2 cases. 1 death.
Vera Cruz, Mexico.....	Feb. 16-23.....	2 cases.

Cholera.

Bombay, India.....	Jan. 29-Feb. 12.....	12 deaths.
Calcutta, India.....	Jan. 26-Feb. 9.....	33 deaths.
Madras, India.....	Jan. 26-Feb. 8.....	22 deaths.
Singapore, Straits Settlements.....	Jan. 12-26.....	35 deaths.

Plague—Foreign and Insular.

Cape Town, Africa.....	Feb. 16-26.....	44 cases. 6 deaths.
Hong Kong, China.....	Jan. 19-26.....	2 cases. 2 deaths.
Bombay, India.....	Jan. 29-Feb. 12.....	1,711 deaths.
Calcutta, India.....	Jan. 26-Feb. 9.....	176 deaths.
Manila, Philippine Islands.....	Jan. 5-19.....	2 deaths.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending March 16, 1901:

DISEASES.	Week end'g Mar. 9.		Week end'g Mar. 16.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	22	12	19	10
Scarlet Fever.....	562	32	608	29
Cerebro-spinal meningitis.....	0	0	0	5
Measles.....	274	8	234	6
Diphtheria and croup.....	261	44	324	58
Small-pox.....	54	10	37	6
Tuberculosis.....	320	170	327	189

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending March 16, 1901: DIEHL, O., Surgeon. Ordered to the *Indiana*, March 15th.

EAKINS, O. M., Assistant Surgeon. His resignation has been accepted, to take effect from April 15, 1901.

McCLANNAHAN, R. K., Assistant Surgeon. Detached from the *Indiana* and ordered home to await orders for sea duty.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from March 9 to March 23, 1901:

BINGHAM, JOHN E., Acting Assistant Surgeon, will report to the commanding officer at Fort Walla Walla, Washington, for duty, to relieve WALTER WHITNEY, Major and Surgeon.

COX, FREDERICK W., Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.

DISNEY, FRANK A. E., Captain and Assistant Surgeon, will report to the commanding general, Department of California, for transportation to Manila.

KEAN, JEFFERSON R., Major and Surgeon, will proceed to Columbia Barracks, Cuba, for duty, relieving ALEXANDER N. STARK, Major and Surgeon.

POND, ARLINGTON, Major and Surgeon, is relieved at Fort Preble, Maine, upon the arrival of ERNEST W. FOWLER, Acting Assistant Surgeon, and then will proceed to San Francisco for transportation to Manila.

Change of Address.—Dr. Horace Laidlaw, to No. 986 Sutter Street, San Francisco.

Dr. S. Weir Mitchell Sails for Japan.—Dr. and Mrs. S. Weir Mitchell left this country on March 15th for a trip to Japan. They expect to return in June, when they will open their cottage at Bar Harbor.

A Physician Mulcted for Allowing Students to Witness an Operation.—Miss Mary Hinman, of Grand Rapids, Mich., who sued Dr. Herrick for \$5,000 because he allowed medical students to witness an operation performed upon her, was recently awarded \$75 damages by a circuit court jury.

Pottstown (Pa.) Declares Consumption Contagious.

—The Pottstown, Pa., board of health has adopted a resolution declaring consumption to be of a contagious and infectious character, and cautions all citizens to treat the disease with the same antiseptic remedies as used in diphtheria and typhoid fever.

Gnats and Mosquitoes.—A new edition of this work by Lieutenant-Colonel Giles, of the Indian Medical Staff, is expected to be ready in May or June, so we are informed by the author in a note from Shahjahanpur, India, the entire first edition of the work having already been exhausted.

Habitual Drunkenness as a Cause for Divorce.—In England the House of Lords has passed a bill that provides special penalties for habitual drunkenness, and also provides that habitual drunkenness shall be treated as persistent cruelty and entitle a wife to divorce. The sale of liquor to inebriates is forbidden.

The Middleton Goldsmith Lecture.—This lecture will be delivered by Dr. Charles Sedgwick Minot, professor of histology and human embryology, Harvard Medical School, at the New York Academy of Medicine, on Tuesday evening, March 26th, at 8.30 p. m. The subject will be The Embryological Basis of Pathology.

Coming Changes at the College of Physicians and Surgeons.—Dr. Francis Delafield will give up the chair of the practice of medicine in the College of Physicians and Surgeons on June 1st. He asked to be relieved of the professorship some time ago, and at the last meeting of the board of trustees of Columbia University, of which the medical college forms a part, his letter of resignation was accepted. At his retirement he will have been a member of the faculty of medicine of the university for twenty-five years. Dr. Walter Belknap James has been appointed lecturer on the practice of medicine at the medical school. His appointment will take effect on June 1st. Dr. Delafield will be emeritus professor of the practice of medicine. His father, the late Dr. Edward Delafield, was president of the College of Physicians and Surgeons from 1858 to 1875.

The State Board of Regents Make Appointments.

—At a meeting of the State Board of Regents, held in Albany on March 14th, Joseph P. Creveling, of Auburn, and Eugene Beach, of Gloversville, were reappointed medical examiners to represent the medical society of the State of New York. Willard N. Bell, of Ogdensburg, was reappointed medical examiner to represent the Homœopathic Medical Society of the State of New York, and John B. Garrison, of New York city, to fill the vacancy caused by the expiration of the term of Edward Chapin. In accordance with the recommendations of the Medical Council to secure the fairest representation of the medical schools of the State, Dr. William Gilman Thompson, of Cornell Medical School, and Dr. Willis G. Tucker, of Albany Medical School, were appointed members of the Medical Council for five and three years, respectively, in place of Dr. Mann and Dr. Didama, the members to retire having been selected by lot.

To Erect a Monument to Dr. Ollier.—Committees have been formed in several European countries for the purpose of receiving subscriptions for a monument commemorative of the distinguished scientific services of

Professor Leopold Ollier. Among the members of these committees are Lord Lister, Professor von Bergmann, Professor Czerny, Professor Durante, and other leading men. The municipality of the city of Lyons has dedicated an open space adjacent to quarters of the various academic faculties on the border of the Rhone, named in his honor Place Leopold Ollier. A committee has been formed in the United States with a view to co-operating with these committees already formed in Europe for the purpose of receiving funds for the erection of the monument in question. This committee is composed of Dr. Robert Abbe, New York; Dr. William T. Bull, New York; Dr. P. S. Conner, Cincinnati; Dr. A. T. Cabot, Boston; Dr. Howard A. Kelly, Baltimore; Dr. W. W. Keen, Philadelphia; Dr. Rudolph Matas, New Orleans; Dr. William J. Mayo, Rochester; Dr. W. F. McNutt, San Francisco; Dr. Roswell Park, Buffalo; Dr. Clayton Parkhill, Denver; Dr. Maurice H. Richardson, Boston; and Dr. Nicholas Senn, Chicago.

The committee hopes to raise not less than one thousand dollars (\$1,000) as a testimonial from the profession in America. Checks should be forwarded to Dr. W. W. Keen, 1729 Chestnut Street, Philadelphia, Pa., and at as early a date as possible.

Small-pox.—Prevalence of the epidemic is reported from Harrisburg, Pa.; Saginaw and Flint, Mich.; Manville, Wis., and in Brooklyn and Manhattan boroughs, New York city. The virulence of the contagion, however, seems to be abating.—The temporary small-pox hospital at Orange, N. J., was destroyed by a mob on March 10th. An unsuccessful attempt had been made to burn it the day before. The health officials have announced their intention of rebuilding the structure, but a contingency has arisen which may defeat their plans. A law passed in 1898 provides that no hospital of this nature may be erected in any municipality without the consent of its governing body. This places the Orange board of health under the necessity of applying to the Orange common council for the required permission, and those who are in a position to know say that it is extremely doubtful if that body will consent. The work of providing for the unfortunate people ill with the disease in a thickly populated neighborhood is now blocked.—Stephen D. Pierce, an immune nurse of Fishkill Landing, N. Y., was arrested recently for leaving two small-pox patients and visiting his friends about the village before the time of isolation was completed. He was sent to the county jail at Poughkeepsie. He will be prosecuted by the State board of health.—Because he was quarantined at his home in Kansas City, Mo., with a small-pox sign on his house, Henry Harrison has sued Dr. T. C. Unthank and Dr. J. L. Harrington for damages. Harrison alleges that on January 14th, last, the physicians said that William Fouse, a relative who lived with him, had the small-pox. Fouse was taken to the pesthouse, Harrison's residence was quarantined, and the head of the family was kept at home for forty-two days. Harrison alleges that it was not small-pox. It is said that the defendants will be prepared to show that Fouse did have the disease pronounced in the diagnosis.—When the Pan-American Exposition at Buffalo opens on May 1st, the American Anti-vaccination League will have an exhibit at the big show. It is the intention of the league to make an exhibit of anti-vaccination literature, to consist of books, newspaper articles, pamphlets, charts, diagrams, engravings, etc., illustrative of the "evil" of the use of vaccine virus.

The St. Louis Medical Society of Missouri.—At the last regular meeting, on Saturday evening, the 16th inst., the following papers were read: Our Present Knowledge of Hydrophobia, by Dr. Carl Fisch; and Recent Modifications of the Pasteur Treatment, by Dr. John C. Morfit.

The Floyd County Medical Society met recently at Louisville, Ky., and elected the following officers: President, Dr. Charles Bowman; vice-president, Dr. E. P. Easley; secretary, Dr. C. P. Cook. Dr. Cook and Dr. Easley were elected as delegates to the meeting of the American Medical Association, and Dr. McIntyre and Dr. E. L. Sigmon delegates to the meeting of the State Association.

The Practitioners' Club of Louisville, Ky.—The Practitioners' Club, an organization composed of Louisville physicians, held its annual meeting and banquet at the Louisville Hotel recently. The following officers were elected: Dr. John J. Moren, president; Dr. C. E. Bloch, vice-president; Dr. D. H. Keller, secretary, and Dr. J. E. Windell, historian. After the business meeting a banquet was served.

The Academy of Medicine of Buffalo, N. Y., was addressed recently by Dr. J. H. Waterman, assistant surgeon of the Hospital for the Ruptured and Crippled of New York city, who chose for his subject Tendon Transplantation. Photographic illustrations were shown of many cases operated on by the speaker. Dr. Herman E. Hayd and Dr. Herman Mynter also made reports of surgical cases of special interest to the profession.

The Society of Medical Jurisprudence.—General N. M. Curtis addressed the Society of Medical Jurisprudence, at its regular meeting on March 11th in the Academy of Medicine, on Capital Punishment—Unscientific and Futile. General Curtis said that capital punishment did not act as a deterrent of crime, but as an actual bar to the administration of justice, owing to the disinclination of juries to cause the infliction of the death penalty.

The Richmond (Va.) Academy of Medicine and Surgery.—The regular semimonthly meeting of the Richmond Academy of Medicine and Surgery was held on March 12th at Richmond, Va., the president, Dr. Stuart McGuire, in the chair. Dr. W. A. Deas read an excellent paper on Cyclic Albuminuria, which was discussed by Dr. Michaux, Dr. Hoge, Dr. Robins, and Dr. Garcine. Dr. M. D. Hoge, Jr., read a paper on The Pathology of the Liver.

The Cleveland Medical Society Mourns Professor Von Pettenkofer's Death.—At the last meeting of the Cleveland (O.) German Medical Society the following resolutions of sorrow and respect were adopted regarding the recent death of Professor Max Von Pettenkofer: "Resolved, That by the death of Max Von Pettenkofer the scientific world has lost one of the greatest scientists, humanity one of the truest benefactors, and the medical world, whose pride he was, an indefatigable worker and pathfinder, whose great loss is irreparable."

The Tri-state Medical Association, in session recently at Richmond, Va., elected Dr. J. N. Upshur, of Richmond, president, to succeed Dr. Kollack. Ashe-

ville, N. C., was selected as the next place of meeting. The other officers elected were: Vice-president for North Carolina, Dr. J. W. Long, of Salisbury; vice-president for South Carolina, Dr. S. C. Baker, of Sumter; vice-president for Virginia, Dr. Hugh M. Taylor, of Richmond; secretary and treasurer, Dr. H. A. Royster, of Raleigh.

Preparing for the Meeting of the American Medical Association.—According to the *St. Paul Medical Journal*, elaborate preparations are under way for the entertainment of the American Medical Association, which meets at that place in June. Dr. J. A. Quinn, chairman of the committee on transportation, hopes to be able to make up a large enough party from the East to come by way of the lakes to induce the steamship line to put on a steamer, though the regular season will not be open by that time.

The Medical Society of the County of Albany.—A regular meeting of the Medical Society of the County of Albany was held on March 11th. The following papers were presented: The Ocular Complications of Influenza, by Dr. C. H. Moore; The Effects of Influenza on the Nasal and Accessory Nasal Cavities, by Dr. Arthur G. Root. The next meeting will be held at Alumni Hall on April 10th. The following papers will be presented: The Relation of the Sympathetic Nervous System to Functional Amblyopia, by Dr. H. S. Pearse; Report of a case in which a scarfpin was swallowed and passed *per rectum* on the seventh day, by Dr. E. A. Vander Veer; a paper, with title to be announced, by Dr. A. Sautter.

The American Laryngological, Rhinological, and Otolological Society.—The council of the society have decided that the seventh annual meeting shall be held at the New York Academy of Medicine, in the city of New York, on May 30th and 31st, and June 1st. The constitution of the society requires that all candidates for admission to the society shall be required to present a thesis when requested by the council, and also, if so desired by the council, such thesis shall be read before a general session or before the section in which the candidate resides. Members who propose to contribute papers should send the titles of the proposed essays to the secretary, Dr. Wendell C. Phillips, 350 Madison Avenue, New York city, at the earliest possible date.

The Medical Society of the County of Kings, at its recent stated meeting at its building, discussed The Scope and Support of Hospitals. Dr. J. T. Duryea spoke on City *versus* Independent Hospitals; Dr. John Harrigan on The Advantage to the Public and to the City of the Non-municipal Hospitals; Dr. A. C. Bunn on Our Church Hospitals, and Dr. W. M. Hutchinson on Municipal as Compared with Private Care of Infants and Children.

The Section of Laryngology, Rhinology, and Otolology considered at its meeting, Thursday evening, Tuberculosis of Ear, Nose, and Pharynx; Dr. B. C. Collins speaking on that of the ear and W. G. Reynolds on that of the nose and pharynx. The Section on *Materia Medica, Therapeutics and Pharmacology* listened to a paper by Dr. James W. Ingalls on Dionin and its Uses, which was discussed by Dr. John Scott Wood, David W. Meyer, and others. The Brooklyn Society for Neurology will hear, on Thursday evening of next week, Dr. T. C. Craig

on Tetanus, and Dr. W. Alfred McCorn on Paralytic Dementia and Cerebral Syphilis, and Dr. E. H. Wilson will give a demonstration on Monday, April 1st, 9-10 P. M., on the Bacteriology of Infectious Diseases.

Proposed Legislation against Hypnotists.—Assemblyman Babcock has introduced a bill at Albany which provides that no person shall practise hypnotism, mesmerism, suggestive therapeutics, and allied phenomena after May 1st, unless previously registered and legally authorized, or unless authorized by the regents. No one can practise who has been convicted of a felony. A fee of \$50 is to be charged. The following requirements for admission to practise are required: A general education; has studied medicine in a medical school for at least two full school years; any one practising who is not authorized to do so, or who advertises in any newspaper, circular, or any advertising medium that they are competent and authorized to practise or teach these arts, shall be guilty of a misdemeanor, and punishable by a fine of not more than \$250 or imprisonment for six months for the first offense; any one who practises under an assumed name shall be guilty of a felony.

The Lorillard Hospital Report Denied.—The report that Mrs. Pierre Lorillard, Jr., contemplated the erection of a hospital on the Riviera for consumptive American women is denied by Mr. Lorillard, in the absence of his wife abroad.

Hospital Changes.—Announcement has been made that Dr. E. Schwarz, president; Dr. M. Seidman, Dr. A. Fischer, Dr. S. Greenbaum, Dr. E. D. Newman, and Adolph Klein have resigned from the directorate of the Newark Hebrew Dispensary and Hospital Association. The trouble that culminated in the resignations arose from the charter members being arrayed against those who became members after by much hard work the organization became firmly established and was recognized as one of the leading Hebrew charities of Newark.

A Memorial Hospital at Cairo to Queen Victoria.—Lord Cromer, the British diplomatic agent in Egypt, and John G. Long, United States consul-general in Cairo, jointly presided on March 8th at an Anglo-American meeting to consider a memorial to Queen Victoria. Both delivered addresses advocating the founding of an Anglo-American hospital, which suggestion was approved by the meeting. Sir Ernest Cassel subscribed £1,000 to the memorial fund, and the subscriptions altogether reached a total of £10,000.

The Annual Report of St. Peter's Hospital, Brooklyn.—St. Peter's Hospital, Brooklyn, has issued its annual report. The hospital is in charge of the Sisters of the Poor of St. Francis, and has been in existence nearly thirty-five years. During the year 3,218 patients were admitted. Of this number 2,559 were discharged and 395 died. The total number of days' service was 89,358. The number of patients treated from the opening of the hospital in 1866 to 1901 was 52,005. Of this total 7,235 were consumptives. The number of consumptives treated last year was 499. Of these 252 were discharged as improved. Six of the hospital wards are set apart for consumptive patients. These contain eighty-four beds.

The Burning of the Orange (N. J.) Pest House Denounced from the Bench.—In his charge to the Essex County Grand Jury, Chief Justice Depue denounced the mob violence displayed at the recent destruction of the

Orange pest house. In part, the charge was as follows: "You all know with what horror you read in the newspapers accounts of mobs in the West and South burning at the stake American citizens simply charged with crime, and who were entitled to have a regular trial. The same spirit that prompted these outrages seems to have reached this county. The newspapers report the destruction of property in Orange by the act of a lawless mob. The excuse for this act, that the location of a pest house was injurious to property, is no justification. If this act be overlooked and excused, a precedent will be established, the consequences of which it is impossible to forecast. The investigation of this case is earnestly pressed upon your attention, that the law may be promptly vindicated by the indictment of these offenders." Five arrests have thus far been made in connection with the wrecking.

New York City's Charitable Hospital Allowance is too Small.—The inadequacy of the provision made by the city for the support of the Department of Charities is dwelt on at length in the annual report of the New York County Visiting Committee of the State Charities Aid Association. There was a net decrease in the total appropriation for the year 1901 of \$63,706. The total appropriation for charities in the boroughs of Manhattan and the Bronx for 1900 was \$1,476,739.97, as compared with \$1,590,732 for 1899, a decrease of \$103,992.03, or six and one half per cent. The appropriation for 1901 is \$1,413,033.97, a decrease of \$63,706.76, or four and one third per cent. less than for 1900. In the opinion of the visiting committee, the principal needs of the various hospitals of the city are as follows: Bellevue Hospital.—Larger quarters for house staff; better quarters for employees; completion of the electric plant; better quarters for prison patients; crematory for refuse and dressings; new laundry building; better regulations of the admission of alcoholic patients.

City Hospital.—Better quarters for nurses; new maternity waiting wards; better accommodations for erysipelas and paralytic patients; a new waiting room at the dock.

Metropolitan Hospital.—Electric lighting plant; proper quarters for employees.

Fordham Hospital.—Ward for children; quarters for employees; better water supply; new laundry.

Harlem Hospital.—New hospital and dispensary.

Gouverneur Hospital.—Quarters for employees.

Speaking generally, the committee says that the city should make better provision for the care of consumptives, and that it should build a convalescent hospital and a lodging-house for women and children. Of the Harlem Hospital, the committee says: "The dispensary is a disgrace to the city; it is a small, low, wooden building, and is far too small for the number of patients who go there. The crowded wards necessitate removals when the patients are too ill to be transferred; still, when those come in who are worse, some must go to give room for them."

Hospital Buildings and Endowments.—The Anna Jaques Hospital, at Newburyport, Mass., which for some years has been seriously cramped for room, will have a new and commodious structure through the munificence of the Hon. William C. Todd, who has donated \$50,000 for a new building and a site valued at \$5,000.—The Free Hospital for Poor Consumptives at Philadelphia has purchased 215 acres of high land in the Pocono regions of Pennsylvania on which to locate a sanitarium.

—By the will of the late State Senator Christopher L. Magee, of Pittsburgh, The Maples, his beautiful home, which was bequeathed to his widow, is left, at her death, or should she at any time decide to leave it, as well as her share in the estate, except her dower interest, for the erection of a free hospital on the site. The hospital is to be known as the Margaret Steel Magee Memorial Hospital, in honor of the mother of Senator Magee. The Mercy Hospital, of which Senator Magee was the president, gets \$10,000.—The new building of the New Jersey State Hospital, at Morristown, is completed, after six years of labor and the expenditure of half a million dollars. The formal opening will take place in the spring, when New Jersey's Governor and his staff will be present.—The Chinese consul at New York, Chow Tsy-chi, with others, has started a movement for the establishment in the metropolis of a hospital for Chinese at a cost of about \$50,000.—Joseph Van Vleck, of Montclair, N. J., has offered \$8,000 toward the erection of a new hospital there.—Over \$4,000 is to be spent on extensive improvements at the Sisters' Hospital at Buffalo, N. Y.—The formal opening of the Hospital for Incurables at Atlanta, Ga., took place on March 12th.—T. M. Shepherd, of Northampton, Mass., has given \$5,000 for the annex to the Dickinson Hospital in that city.—A contribution of \$2,000 has been made to the fund of the new modern hospital planned by the King's Daughters and Sons of Charleston, S. C.—The Hebrew Benevolent and Orphan Asylum Society will build a five-story hospital at Amsterdam Avenue and One Hundred and Thirty-sixth Street, adjoining its present buildings. The cost of construction is estimated at \$70,000.—A new site, satisfactory to all concerned, has been selected for the proposed new Hospital for Incurables at Albany, N. Y.—A small-pox hospital is to be built at Brookfield, Me.—A new hospital to cost \$25,000 is planned for Milwaukee, Wis.—The sum of \$9,101 has been pledged to pay off a \$15,000 mortgage on the Huron Street Hospital, Cleveland, O.—The French Benevolent Society has purchased a site at 450 to 456 West Thirty-fourth Street, New York city, on which it is proposed to erect a hospital to cost some \$400,000. At present the society is conducting a hospital at Nos. 320 and 322 West Thirty-fourth Street, which, on the completion of the new building, will be abandoned. It is likely that an ambulance district will be given the new hospital, partially relieving Roosevelt Hospital.—Articles of incorporation were filed at Albany, N. Y., on March 18th for the Manhattan Maternity Hospital and Dispensary, the incorporators being named as Daniel S. Lamont, Cornelius Vanderbilt, Frank L. Polk, Henry S. Thompson, and William Thorne, of New York; Moses Taylor, of Mount Kisco, and Percy R. Pync, of Bernardsville, N. J. It is said that Dr. J. Clifton Edgar will take a prominent part in bringing this philanthropic scheme to successful accomplishment. According to rumor, the hospital will be the gift of a very rich man, who will not only put up and furnish the building, but will also give it a large endowment. Even the matter of site has not been settled, except that the new institution will be somewhere on the East Side, and negotiations are in progress for a site at First Avenue and Seventieth Street, New York city. So large has been the endowment, it is said, that the hospital and other necessary buildings will take up almost a city block. Most of the beds will be free, but there will be pay beds besides. It is reported that Dr. Russell Bellamy and Dr. J. C. Edgar will be attending

physicians.—A four-story brick hospital and nurser building is to be erected at 216 East Twentieth Street for the Wayside Day Nursery. The building will cost \$32,000.—The directors of the Bethesda Swedis Lutheran Hospital, of St. Paul, Minn., which recently wiped out an indebtedness of \$20,000, are discussing the advisability of building an addition to their hospital.—By the will of the late Colonel Henry E. Roehr, editor and proprietor of the Brooklyn *Freie Presse*, the German Hospital Society of Brooklyn receives a bequest of \$1,000.—Amos Churchill, of Quincy, Mass., recently bequeathed \$1,000 to the City Hospital of that city.—By the will of Stephen Symmes, of Arlington, Mass., the bulk of the property, amounting to about \$25,000, is left to found a hospital and nurses' training school in Arlington. The Symmes place, two and a half acres of high land, with a house and farm buildings, is an ideal location for a hospital. It is about a mile from the centre of Arlington. By the terms of the will the property is left in trust to six citizens of Arlington. These trustees may found and incorporate a hospital and nurses' home; or in case they wish to give up their trust, they may make the property over to the town of Arlington, which shall carry out the provisions of the will. It is safe to say that the trustees will found the hospital and training school. The hospital must be started within five years, but the training school need not come for twenty years. The will provides that the present buildings shall be used but allows the trustees to alter, add to it, and erect new buildings.—The Lancaster County Hospital for the Insane, at Lancaster, Pa., was opened on March 13th.

Births, Marriages, and Deaths.

Born.

EAST.—In Rochester, on Saturday, March 16th, to Dr. and Mrs. Frederick East, a daughter.

PAGE.—In Plattsburgh Barracks, N. Y., on Tuesday, March 12th, to Dr. Henry Page, United States Army, and Mrs. Page, a son.

Married.

BRIDGEMAN—JONES.—In Racine, Wisconsin, on Wednesday, March 6th, Dr. Henry M. Bridgeman, of Cape Town, South Africa, and Miss Florence P. Jones.

HILL—LABARRAQUE.—In Seattle, Washington, on Monday, March 4th, Dr. S. H. Hill and Miss Marie F. LaBarraque.

HYDE—BAKER.—In Greenwich, Connecticut, on Thursday, March 14th, Dr. Fritz Carleton Hyde, of Grand Rapids, Michigan, and Dr. Harriet Virginia Baker.

WALLACE—BOURS.—In San Francisco, on Monday, March 4th, Dr. Arthur Wallace and Miss Lily Bours.

Died.

BRADLEY.—In New York, on Friday, March 15th, Dr. Edward Bradley, in the sixty-ninth year of his age.

BUSTEED.—In Brooklyn, on Monday, March 11th, Dr. John B. Busteed, in the thirty-third year of his age.

CHERRINGTON.—In Salem, Massachusetts, on Monday, March 11th, Dr. Leroy J. Cherrington, in the fifty-sixth year of his age.

DAVIS.—In Plainfield, Connecticut, on Friday, March 15th, Dr. Emery Hawkins Davis, in the fifty-sixth year of his age.

MORET.—In Henry Barracks, Porto Rico, on Sunday, March 3d, Dr. Gustave Moret, United States Volunteers.

PAGE.—In Charlottesville, Virginia, on Monday, March 11th, Dr. John Randolph Page, in the seventieth year of his age.

ROGERS.—In New York, on Tuesday, March 12th, Dr. James H. Rogers, of East Hampton, Long Island, in the seventieth year of his age.

SMITH.—In Escondido, California, on Saturday, March 16th, Dr. Henry M. Smith, in the sixty-sixth year of his age.

Pith of Current Literature.

Medical Record, March 16, 1901.

The Treatment of Gonorrhœa with Frequent Irrigations of Hot Decinormal Salt Solution. By Dr. Charles E. Woodruff.—Considering the germicides added to the water in the modern irrigation treatment, and also their strength, the author is sceptical as to the value of specifics used in this way, and he suggests that plain water would do as well. He assumes that whatever good attaches to the irrigation treatment is attributable to the washing away of the germs and of the toxins, leaving the tissues to destroy the rest. One of the author's patients complained so bitterly of the pain of the germicide that a hot decinormal salt solution was used to soothe the membrane, whereupon the discharge and other symptoms ceased at once. Since then the author has adhered to the use of the salt solution for all cases. His success has been most encouraging, and a report of ninety-eight cases accompanies the text.

A Whistle in the Œsophagus. By Dr. A. E. Isaacs.

The Treatment of Colitis by Valvular Colostomy and Irrigation. By Dr. P. R. Bolton.—The author asserts that, even in favorable cases, only a portion of the mucous membrane of the colon can be reached through the anus, and that to insure contact of the medicating solution with the entire mucous membrane of the colon, fluid must be forced through from the cæcum. He concludes that a simple fistula made in the cæcum would fulfil every indication—one that would admit of the ready introduction of fluids without the annoyance of continuous leakage, and that would finally close spontaneously without requiring any plastic procedure. The plan accredited to Kader he has found best suited to the purpose in view. The case reported justifies the adoption of the principles of the treatment and the method used in the formation of the fistula.

The Ovary; its Relation to Normal Functions and to Pathological States. By Dr. Samuel W. Bandler.—In an extended article the author demonstrates that the relation of the ovary to the normal functions of a special character in women is decidedly clear, and that its relation to pathological states is highly probable. The weaker sex, with its tendency to these affections and to hysteria, will probably in the future be less frequently treated as the possessors of nerves alone. In certain affections he believes that the action of ovarin, verifying, as it does in a measure, the results of animal experimentation, will lead to a more rational treatment of these diseases in the female, both medically and surgically.

The Use of Suprarenal Capsule in Hæmoptysis. By Dr. William B. Kenworthy.

Journal of the American Medical Association, March 16, 1901.

The Study of Anatomy. By Dr. Lewellys F. Barker.—The author concludes that this subject is too wide to be mastered in all its details even when a whole lifetime is devoted exclusively to it. He believes that the scientific anatomist, after familiarizing himself with the main facts and principles of its various subdivisions, does best, in agreement with the great law of division of labor, to direct his efforts toward the acquisition and promulgation of knowledge, in some one portion of it.

Paresis of the External Recti Associated with Irregular Tabes. By Dr. G. Oram Ring.

The Amount of Myopia Corrected by Removal of the Crystalline Lens. By Dr. Edward Jackson.—For a given amount of myopia the effect of removal of the crystalline lens may vary ten D. or more. While statistics indicate that a lengthened anteroposterior axis is the most important cause of very high myopia, other factors of practical importance are variations of corneal curvature, of lens refraction, or of both. These must be considered before we can predict with exactness the effect of an operation. The author urges the more complete and exact study of the ocular refraction and the curvature of the cornea, both before and after the removal of the crystalline lens for high myopia.

On Certain Clinical Features of Epidemic Influenza. By Dr. Howard S. Andrews.—The author points out that the disease has a ferret-like selection for "weak spots"; for the defective strands in the systemic rope, and especially for nerve tissues. He agrees with Huchard that the frequent pulmonary congestions met with indicate lower arterial pressure due to paresis of the vagus and diminished elasticity of the pulmonary vesicles. He adverts to the prominence of suppurative complications, and to the probability of the tonsils being gateways for the entrance of pus staphylococci and streptococci, as well as of the bacilli of Pfeiffer.

Influenzal outbursts are preceded by relatively warm, moist, and calm weather, but prevail with the onset of cold, clear, dry, and windy weather, when the meteorological data show an abnormal increase of the barometric pressure, lower temperature, abnormal temperature ranges, and diminished equability, lower percentage of relative humidity, and increased prevalence of north and northwest winds.

Surgical Circumcision. By Dr. F. C. Valentine.—The author lays stress upon the necessity of observing all the precautions of asepsis and surgical technique. He points out that circumcision, properly performed, is a benefit to the individual and a protection to the community, especially when the prepuce is large, contracted, adherent, or deformed. The operation should be performed by physicians, and the State should protect future generations by compelling the observance of this point. For the sake of religious sentiment, there are many Jewish physicians who could become Mohelim, so that while performing the religious rite, they may conduct it as modern aseptic surgery demands.

Treatment of Laryngeal Tuberculosis at the Montefiore Home for Chronic Invalids. By Dr. W. Freudenthal.—The author emphasizes the fact that there is a pathologic condition which may justly be called pre-tuberculous laryngitis. Remedies potent in the treatment of laryngeal tuberculosis are: (1) The saccharated suprarenal gland for the induction of preliminary local anæsthesia; (2) the menthol-orthoform emulsion for the production of a longer local anæsthesia, and for its curative effects; (3) olive, almond, or sesame oil, for the relief of the dysphagia; (4) phototherapy; (5) heroine for the relief of bronchial cough. He would dispense with lactic acid as an antiquated and barbarous torture to patients.

Treatment of Atrophic Rhinitis by Electrolysis. And some Experiments to Determine the Efficiency of Needles of Different Metals. By Dr. Carolus M. Cobb.—The action of electrolysis in atrophic rhinitis is curative, in so far as it stops the tendency to crust formation and the odor, in typical cases. Neither the discharge nor the odor will be stopped, if these are caused by empyema. The needles should be placed comparatively

near together, and it makes no difference what metal is used in their composition. The improvement in the condition of the nasal mucous membrane is most noticeable in the area around the positive pole. This improvement is probably due to the liberation of oxygen and chlorine, and the chemical change resulting from the presence of free oxygen and chlorine in the tissues, or the acid reaction produced thereby.

The Nature and Treatment of Vertigo. By Dr. J. Leonard Corning.—According to the author, vertigo is primarily a derangement of perception—expanding the term to include also morbid impulses transmitted through afferent nerves other than those of special sensation. This derangement of perception is always accompanied by some improvement of consciousness due to the confusional conditions engendered in contiguous centres of higher mental action. Vertigo, however, may be engendered by direct impairment of the functional efficiency of the centres of perception, without the intermediation of the afferent nerves. As to treatment, only by obtunding the irritability of the cortex can we hope to render the supervention of vertigo impossible. Those remedies are most effective that exert a pronounced sedative effect upon cerebration.

The Pharmacologic Assay of Drugs and its Importance in Therapeutics. By Dr. E. M. Houghton.

The United States Pharmacopœia of Nineteen Hundred. By Dr. Joseph P. Remington.

Astigmatism, its Detection and Correction. By Dr. H. Bert Ellis.

Ureine. Experiments to Discover the Truth of the Recently Announced Discovery by Moor of the True Cause of Uræmia. By Dr. John Weatherson.

Anastomosis of the Ureters with the Intestine. A Historical and Experimental Research. By Dr. Reuben Peterson.

Abdominal Hysterectomy for Multiple Fibroma with Five-month Gravid Uterus. By Dr. George R. Green.

Medical News, March 16, 1901.

Recent Experiences with Erythremelalgia. By Dr. Henry L. Elsner.—The author assails the position of Dr. Weir Mitchell and others who deny the possibility of the association of gangrene, Raynaud's disease, or of other necrobiotic process with erythremelalgia, and he reports cases in point from his own experience and from that of others, which support his contention. Erythremelalgia cannot be dignified as a disease *per se*, and the great variety of diseases which claim it as an attendant is surprising.

The Treatment of the Heart in Typhoid Fever and other Infectious Diseases. By Dr. Albert Abrams.—While the antipyretic effect of the cold bath is a recognized factor in treatment, it must be regarded as possessing only a secondary influence. Its chief action is on the circulatory system. The author asserts that, whenever an error is perpetrated in the hydrotherapeutic treatment, it is in the direction of misinterpreting the effects to be attained by the use of the cold bath; if cardiac vigor is compromised or fails to be improved, the purpose of hydrotherapy is defeated. Until we are willing to dismiss antipyresis as the great desideratum in the treatment of typhoid fever, we cannot hope to obtain better results than at present. The theory which most cogently appeals to reason is that which assumes that the action of the cold bath is secured by stimulation of the peripheral cutaneous nerves. A procedure recommended

by the author, and for convenience called a *friction bath*, is, in practice, as follows: The patient is first rubbed or sponged with alcohol, and this is followed by vigorous cutaneous friction until the skin glows. The results of this method upon the circulatory apparatus and nervous system are very gratifying. The *siphon method* is also suggested by the author for its simplicity and efficiency, and consists in gradually discharging the carbonated liquid from a siphon bottle over the surface of the body, and particularly on the thoracic region.

A Report of Three Cases of Thoracic Aneurysm Treated by Subcutaneous Injections of Gelatin. By Dr. Lewis A. Conner.—Lancereaux states that such injections cause no pain and produce neither local nor general reaction. These statements have not been confirmed by most of the other investigators, and the author's experience would seem to demonstrate that, whatever the curative value of the treatment, its usefulness is seriously impaired by the severe pain that frequently follows the injections.

Observations upon the Amœbæ Coli and Their Staining Reactions. By Dr. Charles F. Craig.—The author's study of the stained specimens seems to demonstrate: (1) That vacuolization is a degenerative process, as the young amœbæ and the full-grown healthy ones show no vacuoles; (2) that the small, round or oval, unstained areas, occurring in all but the degenerate amœbæ, reasoning from analogy, are spores; (3) that peculiar structures occurring in the protoplasm of the amœbæ, and not bacterial in nature, may be certain crystals which occur in the fæces and which have been absorbed by the amœbæ; (4) that degeneration takes place by vacuolization and by fragmentation.

A Preliminary Note on the Relation of the Form of the Tubercle Bacillus to the Clinical Aspects of Pulmonary Tuberculosis. By Dr. Henry Sewall.—The author believes that the form of the tubercle bacillus is an important indication of the virulence of the tuberculous process. The short, deeply-staining rod, or chain of rods, of moderate length, is the usual form in many active cases. The long rods, particularly if irregularly broken, betoken a milder process, and the chains of spore-like beads characterize the very chronic cases. A rather long, slender rod, ill-staining, is found in cases apparently passing on to cure. The bacillary characters of the sputa of the same individual seem at different periods to vary as the state of the disease.

Rhinoscleroma. By Dr. H. Jarecky.

Subglottic Growths; Report of Cases. By Dr. Robert C. Myles.

Philadelphia Medical Journal, March 16, 1901.

Strangulated and Gangrenous Hernia. Kelotomy and Laparotomy in Strangulation, External and Internal; Artificial Anus—Enterostomy, Primary or Secondary Resection—Enterectomy, and End-to-end or Lateral Jointing in Gangrenous Hernia. By Dr. Thomas H. Manley.—In an extended text-book article the author treats of the subjects indicated in the title. He remarks that radical revolutionary methods are adopted, very properly, by the profession, with great reserve, and the more ancient procedures, established and promulgated by eminent authority, are set aside with reluctance. He agrees, however, with Southam that the high mortality in strangulated hernia is due largely to two causes: First, delay in operating; and, secondly, from the injury previously inflicted on the contents of the hernial sac by forcible, prolonged, and repeated taxis.

A strangulated hernia delayed for operation for more than four days shows that there is still much missionary work to be done. With patients, however, averse to radical surgery, or for other cogent reasons, judicious taxis alone, or combined with other resources, will often effect the reduction.

Two interesting cases are given which illustrate a large class of adherent hernias in strangulation, in which consecutive or post-operative symptoms of a grave character may be usually entirely obviated by *limiting our intervention to intestinal liberation* and leaving undisturbed widespread adhesions, through which, in its new abode, the intestine derives its nutritive supply. (*To be continued.*)

Percentage and Laboratory Feeding. By Dr. J. P. Crozer Griffith.—The author is highly in favor of percentage feeding, and he believes that considerable misconception exists as to what percentage feeding really is, and that mistakes arise on that account. One of the secrets of successful percentage feeding, he states, is to begin with low percentages. Though woman's milk contains fat 4 per cent., proteids 1 to 1½ per cent., and sugar 7 per cent., it is by no means advisable to start any baby upon this strength of a milk mixture.

A Contribution to the Technique of the Widal Test. By Dr. A. Robin.—In this test, if the reaction is positive, the author points out that all, or nearly all, the bacilli will be found to gather in clumps of two, three, or a dozen, and will soon lose their motility, while in a pseudoreaction only a few clumps will form. The test can generally be more satisfactorily performed with an oil immersion. The time limit is a very important point, and the author observes that, if within two hours clumping and loss of motility do not take place, the reaction is negative. The dilutions to which this time limit is applied are of the strength of from 1:100 to 1:500. The skill involved in the application of this test is just such as should be possessed by any intelligent physician who had received his instructions in an up-to-date medical institution.

Rupture of the Rectum and Hernia of the Intestines in an Insane Man. By Dr. A. R. Moulton.

Removal of the Right Upper Cervical Sympathetic Ganglion for the Relief of Glaucoma Simplex. By Dr. D. H. Coover.—From this case the author concludes that the operation is of no service where the vision has been reduced to zero, but it may be of service in arresting the disease in the earlier stages, and preserving vision before atrophic changes have taken place in the nerve, retina, and choroid. The operation in skilful hands is not a dangerous one.

A Synoptical Report of 1,141 Cases of Indigent Visitors Treated at Hot Springs, Arkansas. By Dr. Howard Paxton Collings.

Boston Medical and Surgical Journal, March 14, 1901.

The Story of the Boston Society for Medical Improvement. By Dr. J. G. Mumford.

Notes from the Neurological Department of the Massachusetts General Hospital. By Dr. W. E. Paul.

Intestinal Anastomosis. By Dr. Charles G. Cumston.

A Case of Cæsarean Section. By Dr. Herbert J. Keenan.—The surroundings were those of the poorer sections of South Boston. An oil lamp on the wall supplied light. The instruments used were those of the ordinary pocket-case. The child and placenta were de-

livered in less than five minutes; the abdominal wound closed, and the patient in bed in fifty minutes. Mother and child did well until the sixth day, when, in a fit of coughing, the wound opened through its entire length and the intestines escaped. Under chloroform the intestines were replaced and the wound was once more closed up, after which recovery was uneventful.

Lancet, March 9, 1901.

Public Health and Housing: The Influence of the Dwelling upon Health in Relation to the Changing Style of Habitation. By Dr. J. F. J. Sykes.—In the second of the Milroy lectures upon this subject, the author continues his discussion of the healthfulness of the various classes of dwellings—tenement-houses, "flat" houses, and underground dwellings. It is curious to note that in houses of six storeys and over the basement is fifth in order of mortality, and not first, as would be expected. Most of the faults of the construction and arrangements of dwellings give rise to impure air and may be classed as air deficiencies and effluvia. The only conditions that may be regarded apart from deficient and impure air are coldness, dampness, deficient light, deficient water supply, and general atmospheric impurity. The various methods for laying out street blocks for dwelling-houses are considered. When houses are constructed in parallel rows, with no houses on the streets at right angles, the square orientation of the street block (*i. e.*, squarely in line with the cardinal points of the compass) provides the maximum of sunshine. But when houses are built around all four sides of rectangular street blocks, the diagonal orientation secures most sunshine. In conclusion, the author describes the various classes of domestic buildings and dwellings, and their internal arrangements for light, air, water supply, etc. It is a mistake to provide large rooms for the poorer classes, as it leads to overcrowding, the placing of more beds in the rooms, and the mixing of the sexes.

The Statistics of Gastric Ulcer, with Special Reference to Gastric Hæmorrhage, its Frequency and Fatality. By Dr. Byrom Bramwell.—The author takes issue with Mayo Robson's conclusions as to the frequency of gastric ulcer, the fatality of gastric ulcer, and the frequency and fatality of hæmorrhage in cases of gastric ulcer. He first points out the inaccuracy and unreliability of the two methods (post-mortem and clinical) of determining the frequency of gastric ulcer in the general community. Robson's estimate of five per cent. is probably excessive. In 17,226 cases of general medical diseases seen by the author, there were 202 cases of gastric ulcer = 1.1 per cent. The total fatality from gastric ulcer is estimated by Robson as 25 per cent. According to this, 81 persons should die annually from gastric ulcer in a city of 500,000 inhabitants. Leeds is such a town, but only 17 deaths from gastric ulcer took place there last year. Most authorities place the total mortality from gastric ulcer at from 8 to 15 per cent. Robson states that hæmorrhage in gastric ulcer, when treated medically, proves fatal in from 3 to 11 per cent. of the cases. The author has seen but one death from hæmorrhage in 126 cases of gastric ulcer (he excludes a case of duodenal ulcer), a percentage of 0.77.

Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. By Dr. L. M. Bruce.—The first of the Lettsomian lectures. After the age of forty years many of the influences that threaten the heart and arteries with disorder and disease are peculiar to this period of life; that is, peculiar and distinct from the

causes of cardiac and vascular affections in childhood, adolescence, and manhood. These influences are discussed by the author under the following heads: (1) Physical stress in the forms of sudden violent exertion and ordinary laborious occupations; (2) nervous influences, such as overwork, insufficient sleep, etc.; (3) extrinsic poisons, such as alcohol, tobacco, tea, coffee, and lead; (4) disturbances of metabolism, including gout; (5) syphilis; (6) acute diseases, such as rheumatism, influenza, and diphtheria, as well as septicæmia; and (7) chronic diseases such as pernicious anæmia, Graves's disease, etc. One of the most interesting causes of cardiac disease in advanced life is premature old age of the heart and blood-vessels. Degeneration of the muscular and other cells sets in early, reminding one of the essential myopathic paralysis in children. Such cases of premature arterial sclerosis are often hereditary.

Pure Urea in the Treatment of Tuberculosis. By Dr. H. Harper.—During the past nineteen months the author has used pure urea in a large number of cases of different forms of tuberculosis, and believes it to be a remedy of superior value to any that is used for this disease at the present time. He reports nine cases of pulmonary tuberculosis treated with urea, six of which he regards as cured; tubercle bacilli are still present in the sputum of the other three. In all, the diagnosis was confirmed by microscopical examination of the sputum. Nearly all were hopelessly bad cases, such as the author had never before seen to show any signs of improvement. In only two cases was there any increase in the amount of urea excreted. The tubercle bacillus fails to grow in meat broth to which from 1. to .001 per cent. of urea has been added. The urea was given both hypodermically and by mouth, in doses of twenty grains three times a day. On two occasions this treatment has called forth symptoms of gout.

A Case of Pemphigus Neonatorum in an Infant Three Days Old. By Dr. C. J. Glasson.—The author reports a case of pemphigus neonatorum in an infant three days old, in which no history or indication of parental syphilis could be made out. The eruption covered the whole body, consisting of bullæ containing cloudy fluid and surrounded by a bright red ring of inflammation. Each spot was opened with an aseptic needle, the whole body washed in a rainwater bath, and the spots dressed with boric ointment. After three days there was the greatest improvement, and the child never thereafter showed the slightest manifestation of hereditary syphilis. On the ninth day the whole of the outer cuticle began to peel off like a glove, no part of the body escaping. Minimum doses of liquor arsenicalis were given internally throughout.

A Few Cases of Ethyl Chloride Narcosis. By W. J. McCordie, M. B.—The author gives short notes of ten cases in which ethyl chloride was successfully used as an anæsthetic. Anæsthesia is quickly induced (in about two minutes) and as rapidly passes off. Its main disadvantage is that muscular relaxation is not generally complete. Rigidity may be marked in muscular, especially in alcoholic, subjects. The best mask to administer from is that of Breuer. Complications during the induction or continuance of anæsthesia appear to be rare, chiefly of an asphyxial kind and dependent on some mechanical factor. As a preliminary to etherization, ethyl chloride is most successful.

A Further Note on the Production of Local Anæsthesia in the Ear, Nose and Throat. By Dr. A. A. Gray.—The author's method for obtaining local anæsthesia in

the ear, nose, and throat is as follows. Two solutions are made: (1) a twenty-per-cent. solution of cocaine in rectified spirit; and (2) a fifteen to twenty-per-cent. solution of eucaïne in aniline oil. Before use, the bottle containing solution No. 2 is well shaken up, and ten minims (measured) are poured out; to this are added ten minims of solution No. 1, and the mixture becomes clear in a few seconds. This gives the following formula: Cocaine hydrochlorate 10 parts, β eucaïne 10 parts, aniline 50 parts, and rectified spirits 50 parts. In applying the solution (not more than twenty minims of which should be used) the anæsthesia is enhanced if the solution is rubbed gently over the part for a few seconds by means of a pledget of cotton wool on the end of a probe. A period of at least seven minutes should be allowed to elapse, when anæsthesia will be found to be complete. This solution works very satisfactorily in the removal of tonsils, spurs of the sæptum, cauterization, and all ear work.

Two Cases Illustrating the Use of the X-rays in Surgery. By G. P. Newbolt, F. R. C. S., and C. T. Holland, M. R. C. S.—The authors report two cases, illustrating the great value of the x-rays in surgery. In the first case, one of pistol shot wound of the face, in which the bullet could not be located, the skiagram showed it to be beneath the masseter muscle, whence it was easily excised. In the second case, one of difficulty in swallowing, following a fall, the skiagram showed the trouble to be a vulcanite tooth plate which had lodged behind the larynx. It was easily removed with forceps.

British Medical Journal, March 9, 1901.

The Neglect of the Actual Cautery in Surgery and its Value in the Treatment of Pruritus Ani. By Sir W. M. Banks.—The author calls attention to the undeserved neglect into which the use of the actual cautery has fallen. In cases of syphilitic periosteitis and other bone mischief, the cautery, if thoroughly applied, will initiate a cure when everything else has failed. The instrument should be white hot, and should be pressed many times over the same track. In certain conditions of the knee-joint the actual cautery can be applied with immense advantage. Tuberculous disease of the knee is not benefited by it, but in cases of sprains and synovitis in gouty subjects, "firing" with the cautery will almost always do good. In fairly acute inflammatory conditions of the spinal column and the spinal meninges after injury, accompanied by paralysis, actual cauterization has worked wonders in the author's hands. In these cases he burns completely through the skin in three or four places, each having an area of about an inch and a half. But the chief purpose of this article is to call attention to the great value of the actual cautery in pruritus ani. The vast majority of ordinary cases of pruritus are curable by finding out and doing away with what produces them. It is only in severe cases where no reasonable cause can be found that he recommends the use of the cautery. In the last twenty years he has used the cautery for pruritus ani not more than a dozen times. But the very value of the remedy lies in its being unfailingly curative in absolutely intractable cases. The big bulb of the cautery is applied very freely to the anus, the resulting burn healing very quickly.

Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. By Dr. J. M. Bruce.—The first of the Lettsomian lectures on this subject. See abstract of the *Lancet* for March 9, 1901, in this number of the *Journal*.

The Influence of the Dwelling upon Health. By Dr. J. F. J. Sykes.—The second of the Milroy lectures on this subject. See abstract of the *Lancet* for March 9, 1901, in this number of the *Journal*.

The Histology of the Urinary Tract in its Relationship to Morbid Urinary Deposits. By G. L. Eastes, M. B.—The author has studied the epithelium of the urinary tract in health and disease, and among the conclusions arrived at are the following: In the course of over 6,000 examinations of urine from cases of nephritis, he has never been able to convince himself that he has seen the clear, flattened epithelial cells peculiar to the Malpighian corpuscles; he has, however, recognized in many cases the granular rod-shaped epithelium of the convoluted tubules. The cubical or columnar epithelium of the latter part of the tubules is easily recognized, and is the kind most commonly found when renal epithelium is present. In cancer of the kidney there is usually an abundance of renal epithelium, but the cells are not isolated as in nephritis, but are to be found in clumps, numbering from four to twenty cells. The cells are dovetailed together, and their presence points to rapid proliferation. In cases of buried calculus, the following indications are suggestive: The deposit contains blood, though little, with the characteristics of renally derived blood, a few hyaline casts, and several epithelial cells from the collecting tubules, but no epithelial casts. There is always much free uric acid and a history of tender kidney with reflected pains. The renal pelvis possesses a very distinctive epithelium, belonging to the "transitional" type. These cells are present in the urine in cases of stone in the pelvis of the kidney, and in pyelitis. In these cases the urine contains more albumin than is warranted by the microscopical examination. The renal pelvis may contain neoplasms, usually of the papillomatous variety, and the writer has been able to diagnose this condition from an examination of the urinary deposit. Groups of cells and isolated cells in large numbers accompanied by blood, the cells of a most pleomorphic character, but usually tending to a fusiform or spindle shape. The bladder epithelium is also of the "transitional" variety, but the individual cells are much larger than those of the renal pelvis. In cystitis the cells are usually derived from the surface of the epithelium, and there are few of the characteristic pear-shaped cells of the deeper layers. In epithelioma, the cells are more pleomorphic; they come away in groups, are granular, and have large nuclei. In cases of villous growth (malignant papillomata), the cells are of exceptional length and thinness. Urethral epithelium is usually disorganized when seen in urinary deposits. In gonorrhœa there is much urethral epithelium, but it is swollen and altered in appearance. In the urine of boys between the ages of fourteen and twenty (the period of prostatic growth) the author has found clumps of clear, luminous, pear-shaped cells imbedded in a mucoid material. No such cells occur in the urine of girls, so that he believes them to be of prostatic origin.

Remarks on a Case of Electric Shock. By H. Smurthwaite, M. B.—The author reports the case of a man who received a shock from an alternating current of 2,150 volts, the current passing from the dynamo through a bunch of keys in the man's pocket, through the body, and the right hand, with which he was adjusting the brushes of the machine. The thigh was severely burned, as was also the right hand, the first phalanges of the forefinger and thumb of which had to be amputated. He was unconscious for two hours. An

interesting point in the case was the large amount or high pressure of electricity that passed through his body without causing death (2,150 volts). In America, where "electrocution" is practised, 1,500 volts is considered sufficient to kill.

Gazette hebdomadaire de médecine et de chirurgie,
February 24, 1901.

Inguinal Adenopathy in Cancer of the Rectum.—M. Charles Viannay records two observations in which true inguinal adenopathy complicated cancer of the rectum. The glands were shown by histological examination to have been invaded by carcinomatous tissue. The invasion of the inguinal glands may be of diagnostic value, as in one of Viannay's cases, in which the enlarged glands were the first cause of complaint. In performing radical operations for the relief of rectal cancer, the inguinal glands must be removed if they are involved.

Presse médicale, March 2, 1901.

Antituberculous Dispensaries in Liège. By M. E. Malvoz.

Myeloid Reaction. By M. H. Dominici.

Wiener klinische Wochenschrift, January 24, 1901.

Ocular Emphysema.—Professor Ernst Fuchs says that emphysema of the lids is the most common form of the condition about the eyes. It occurs less frequently in the orbit or in the connective tissue. It may arise from a communication between the air-containing cavities—most frequently the nose and its accessory chambers—and the orbit, the lids, or the connective tissue, by means of a cleft; or, by the entrance of air from these cavities in forced expiration; or, by the absence of a wound communicating with the external world which would allow the extravasated air an easy exit. It may follow sneezing, for instance, or it may appear spontaneously. The prognosis is good, as the air is usually absorbed in a few days under a pressure bandage, with avoidance of winking and pressing on the patient's part.

Treatment of Typhoid with Jez's "Antityphoid Extract."—Dr. Valentin Jez and Dr. Franz Kluk-Kluczycki observe that the antityphoid extract, originated by Jez, is a specific only against typhoid fever; that it is harmless and produces no disagreeable sequelæ when given in large doses. It is useful in establishing a diagnosis; and, if administered uninterruptedly in a case of typhoid fever, it reduces the temperature and stimulates the pulse. It shortens the course of the disease and diminishes or neutralizes completely the effects of the typhoid toxins. It may be given by mouth and does not then evoke any disagreeable symptoms such as follow its subcutaneous administration.

Echinococcus Disease. By Dr. Heinrich Kokall.—A statistical study.

February 14, 1901.

Transitory Influence upon the Knee-jerk by Cerebral Affections.—Professor A. Pick, in an analysis of four cases of cerebral disease or injury, draws attention to the temporary absence of the knee-jerk and its subsequent appearance. He thinks the phenomenon most easily accounted for by assuming a temporary affection of the cord, either inflammatory or due to pressure of blood from hæmorrhage.

Mechanical Treatment of Certain Forms of Vertigo. (See *New York Medical Journal*, March 9th, Therapeutical Notes.)

Iodipin as a Diagnostic Measure. By Dr. Franz Werner.

Deutsche Medizinal-Zeitung, February 21, 1901.

Chronic Gout.—Dr. C. von Heidler-Heilborn writes of the difficulty of always diagnosing chronic gout. He speaks of the larvated forms of the disease which manifest themselves in dyspepsias and neuralgias, especially of the sciatic nerve, the tendo Achillis, and the dorsum of the foot. These are often accompanied by changes in the fingers and great toe, which are disclosed only by minute examination. Carefully selected, plain diet, massages, exercise, baths, and alkaline remedies are the means of treatment which the author has found most useful. He does not think highly of colchicum, piperazine, or medicine in chronic gout.

Wiener klinische Rundschau, February 10, 1901.

Thickening of Peripheral Nerves in Neuritis Following Colds.—Dr. Heinrich Popper says that many cases of neuritis date from a cold. The exposed nerves, such as the facial, the cervicobrachial nerves, the crural, and sciatic, are most likely to be affected. Sometimes palpable thickenings are evident, which may appear in single branches only or be symmetrically distributed in the extremities. Occasionally an increased reflex excitability may be noted.

Metabolism in a State of Hunger (concluded). By Dr. E. Freund and Dr. O. Freund.

Vegetarianism. By Dr. W. Thurn. (*Continued article.*)

Centralblatt für Chirurgie, February 16, 1901.

Mechanical Treatment of Inguinal and Femoral Hernia.—Dr. H. Wolfermann describes in detail a patented hernia truss of his invention, which, owing to its mechanical principles, holds a hernia well in all postures of the body.

Centralblatt für Gynäkologie, February 23, 1901.

Sensitiveness of the Peritonæum.—Professor K. G. Lennander draws the conclusion from his researches that the parietal peritonæum is richly endowed with nerves of sensation. The stomach, intestines, and mesentery, however, are insensible to pain or to touch, and patients are unable to distinguish between heat and cold applied to these organs. The gall-bladder, liver, and kidneys are equally lacking in sensitiveness. The author explains intestinal colic as due to the pressure upon the parietal peritonæum, of rapidly distended gut. Lennander has operated upon inguinal and femoral hernias and a Meckel's diverticulum under local anæsthesia, using Schleich's solution No. 2, and infiltrating each layer as it is approached. He believes that the anæsthesia of the future for abdominal operations will be a combination of general narcosis and local anæsthesia.

Riforma medica, January 18, 19, 20, and 21, 1901.

A Contribution to the Study of the Histological Changes in the Kidneys in Poisoning by Corrosive Sublimate. By Dr. B. Vasoin.—The author's conclusions are as follows: 1. A dose of corrosive sublimate even smaller than one centigramme can produce well-marked lesions in the epithelium of the uriniferous tubules of the rabbit. These lesions consist in degeneration and necrosis of the epithelial cells, especially in the convoluted tubules. 2. These lesions vary according

to the chronicity of the poisoning. 3. Acute poisoning produced by subcutaneous injection results in diffuse hæmorrhages and in a detachment of the epithelium from the basement membrane without altering the cells themselves. 4. In less rapid poisoning the lesions vary according to the mode of entrance to the poison. If the poison enters by the gastric route there is a parenchymatous nephritis; if it enters subcutaneously there is a necrosis of the epithelium of the convoluted tubules and sometimes of the straight tubules. 5. The necrosis has the characteristics of a hyaline coagulation. 6. Deposits of calcium salts are found in the masses of necrotic epithelium; these concretions are probably derived from the small quantity of calcium which normally circulates in the blood. 7. In chronic sublimate poisoning there is an increased amount of glucose in the blood.

January 22 to February 1, 1901.

Extirpation of a Tumor in Broca's Centre. Recovery. By Dr. A. Carle and Dr. B. Pescarolo.—In this case the recovery was so complete, and the time of observation after the operation so protracted, that the authors decided to publish the results. The patient was a man aged thirty-eight years, a baker, without any syphilitic history. In February, 1896, he was seized by what was described as an epileptic attack. He remained unconscious for an hour, and awoke complaining of a severe pain in the head, which persisted in spite of a variety of remedies. This pain was diffuse, but especially marked on the left side. A progressive defect in his intelligence was noticed by his family from that time on, and a difficulty in speech appeared, involving an inability of finding the proper words. He never had any more convulsive attacks, but had frequent moments of unconsciousness or semiconsciousness (*petit mal?*). On examination, it was found that the right hypoglossal nerve was paralyzed, that there was a paresis of the right inferior branches of the facial, together with a slight diminution in the motive power of the right extremities, an increase of the right patellar reflex, the absence of the clonus of the right foot, and a diminution of the cutaneous reflexes on both sides. The eye fundus of the left side showed an œdema of the border of the optic disk which was less marked on the right side. The patient presented the characteristics of melancholia with frequent accesses of stupor. His aphasia was very marked, but varied from day to day. He did not show any word-deafness, but exhibited a type of motor aphasia. The diagnosis of cerebral tumor was made, and the new growth was located in the third (left) frontal convolution. The Rolandic fissure was found by the method of Lucas-Champonnière and osteoplastic resection of the skull was performed in the region thus marked out. A tumor about three centimetres in diameter and ovoid in shape was discovered at the lower part of the third frontal convolution. This was removed as completely as possible. At first it was impossible to replace the bony flap on account of a cerebral hernia which followed the operation, but this hernia disappeared later and the flap was successfully replaced. After the operation there was a rapid recovery from the aphasia, the melancholia, and the paresis.

Changes in the Cellular Protoplasm of the Skin and of the Leucocytes under the Influence of some Poisons. By Dr. Leopoldo Baruchello.

Roseola-like Eruption Due to the Injection of the Salicylate and the Protochloride of Mercury. By Dr.

Vittorio Allgeyer.—The author reports a case of recurring eruption of the roseolous type in a man who had been treated by intramuscular injections of the salicylate and the protochloride of mercury. The patient was in the secondary stage of syphilis. The erythema showed itself in the form of lenticular macules, circular spots, and irregular figures. This erythema appeared six times within a year, each time after an injection of salicylate or of protochloride of mercury (calomel). The fact that these eruptions were not mere signs of a general idiosyncrasy toward mercury was proved by the use of mercury internally and in the form of inunctions, which gave no eruptions, while the injections invariably were followed by the erythema. The author found, further, that five centigrammes of the salicylate could be injected into the skin without producing any eruption, while seven or eight centigrammes were sufficient to cause an erythema.

Concerning Massive Cancer of the Liver. By Dr. Virgilio Bolli.—Primary cancer of the liver is comparatively rare, and may exist as nodular cancer or as a diffuse new growth involving the entire glandular mass of the organ. The name *massive cancer* has been applied to the last class of cases by French physicians. The author reports a case of this kind in a woman aged thirty-five years. He concludes that the diagnosis of diffuse cancer of the liver is extremely difficult because the symptoms which accompany this affection are so similar to those of other diseases of the liver. In the present case there was no hypertrophy of the liver, and the author believes that this is the first reported case of *cancer massif* of the liver in which the organ affected showed no increase in size. In this instance there was a secondary cancer of the stomach which was diagnosed clinically, and which was the immediate cause of the patient's death.

The Origin and Distribution of the Pathogenic Germs Found in the Water of the Port of Cagliari. By Dr. V. E. Malato Calvino.

Splenic Anæmia as a Morbid Entity. By Dr. Tommaso Guida.—A critical examination of the literature of the subject, together with an analysis of the author's own experience, has enabled him to draw the following conclusions: Splenic anæmia should not be regarded as a disease of childhood, but as a syndrome closely allied to other diseases, such as tuberculosis. The causes of this syndrome may be summed up by the word malnutrition. It may be prevented by careful attention to the nutrition of the child, by noticing certain signs of insufficiency of feeding before they become threatening, especially by watching the weight curve, and by regulating the amount and quality of the food in such a way as to prevent malnutrition. If the nutritive disorders are due to some specific cause, we must recur to other means of treatment. Thus, hereditary syphilis, congenital maldevelopment, insufficient and improper feeding, and lack of proper hygiene, predispose to the syndrome which is known as splenic anæmia. Cases of this affection are becoming more rare of late because the public is becoming more intimately acquainted with the principles of hygiene and infant feeding. It is important to watch the pale color of a child's skin, and if, in addition, we have an enlarged spleen, it is high time to interfere and to improve the feeding. In many cases it is possible to restore the patient to health by these means, but if the spleen continues to enlarge, and the cachexia continues to grow worse, all forms of treatment will probably be in vain.

Gazetta degli ospedali e delle cliniche, January 6, 1901.

Concerning Certain Experimental Researches on Antituberculous Serums by Maffucci and Di Vestea. By Dr. E. Maragliano.—The author criticises the experimental work of Maffucci and Di Vestea, of Pisa, because these observers failed to control their results by injections of a "test-gift" in the manner described by Maragliano. The test-poison used by them contained fifty per cent. of glycerin, and the author states that the glycerin alone is capable of killing the guinea-pigs. Hence the use of glycerinized tuberculin as a test-poison is simply a waste of time and animals. If the observers had used tuberculin prepared as Maragliano described they would have to deal only with the toxic power of the tuberculin and their experiments would be of value.

A Case of Epitheliomatous Epulis of the Gingival Mucosa with Telangeiectasic Centres. By Dr. C. Molé.

Small-pox and Immunity after Vaccination. By Dr. F. Ubertis.—An account of the effects of vaccination in an epidemic that occurred recently in Acqui. In Ponzzone, a village not far distant from Acqui, there were no cases of small-pox in spite of the close proximity and the freedom with which the inhabitants of the last-named place went to Acqui, the infected village, in the course of their business. In two persons in Ponzzone the existence of small-pox was suspected, but they were discharged after a few days' detention. In Cavatore, a commune situated between Ponzzone and Acqui, only a fraction of the population was vaccinated when the epidemic broke out, and a number of cases occurred in this village. When the inhabitants had been systematically vaccinated the epidemic was arrested. Although the author vaccinated over one thousand persons, he did not find that, as has been stated, vaccination during an epidemic predisposed to infection. Only a few persons were attacked within a few days after vaccination, and in these the infection probably existed at the time when the preventive inoculation was made. In all these persons the attack was comparatively mild and left few or no scars.

Vratch, January 27, 1901.

The Significance of the So-called Thorax Paralyticus. By Dr. I. G. Gabrilovitch.—The author, who is head physician of the Imperial Sanatorium for Tuberculosis in Chalila, Finland, and whose researches on the value of electricity in the treatment of consumption were abstracted in this column at the time of their appearance, devotes an elaborate article to the consideration of the deformity of the chest known as paralytic thorax. This term was first applied by Engel in the 'forties of the past century to a deformity of the chest characterized by a widening of the intercostal spaces and an elongation of the whole thorax. He supposed that this deformity arose from the paralysis of the intercostal muscles. Rokitansky and others soon afterward described the thorax of tuberculous subjects, and the characteristics of these chests were the same as those of the paralytic thorax, with the addition of the alar scapulæ, the low position of the clavicles, and the alteration of the angle of Ludwig (Freund and Aufrecht). At present the term paralytic thorax is applied as before to chests which show the characteristics described above. The significance of paralytic thorax, however, is not known, as we have no recorded measurements of the chests of consumptive subjects. For this purpose the author undertook a series of measurements so as to find the relation of the elongated thorax to the

predisposition to tuberculosis. He measured the chests of perfectly healthy persons between the ages of twenty and thirty years. In thirty such individuals he found that if the circumference of the chest was taken as 100, the height of the body would be 180; in other words, that the circumference was to the height as 1.0 was to 1.8.

The most favorable ratio between the height of the body and the circumference of the chest was 1.6:1.0, while the least favorable figure in normal individuals was found to be the ratio 2.0:1.0. The average ratio of the circumference of the abdomen to that of the chest was 0.89:1.00. The length of the trunk was measured from the suprasternal notch to the upper border of the pubic symphysis. The ratio between this measurement and the circumference of the chest was found to average 0.62:1.00. The ratio between the anteroposterior and the lateral diameter of the chest (at the level of the sternal protuberance for the first, and at the level of the middle axillary line where it crosses the fifth rib for the second) averaged 0.7:1.0.

The same measurements were then undertaken in tuberculous subjects, seventy-four in all, and the author gives the results in a series of charts. He concludes that the thorax of the tuberculous subject is characterized by the following peculiarities: It is elongated and narrowed in the lateral diameter, while the circumference is usually one half of the height of the body. The paralytic thorax, as described by most authors, is but rarely seen in consumptives in the first or second stage of the disease, but it is seen in the third stage as the result of the great cachexia. The thorax found in consumptives is probably the result of hereditary predisposition toward an elongated chest.

Corporal Punishment in Russia in the Twentieth Century. By Dr. D. N. Jbankoff. (*Continued.*)—The author gives a number of facts and statistics from the records of the courts and from the accounts of the daily press concerning the prevalence of the barbarous custom of corporal punishment in Russia at the present day. Employers flog their workmen in shops and factories; girls are whipped in dressmaking and millinery establishments, without any authority other than the right of the strong over the weak. Corporal punishment of children by parents and teachers is so common that it excites no comment; only occasionally, when such punishment is followed by disastrous results, does such an affair reach the courts. In the country there is more whipping, beating, and flogging than in the city, because the population is so largely made up of persons of the lower classes, who can be beaten for certain petty offences at the sentence of a court. The husband, who can be flogged at the police station for being found drunk on the highway, beats his wife as much as he pleases. The Russian peasant woman takes blows from her husband as a matter of course, as a part of the conjugal duty. There is even a Russian proverb which says: "If he does not beat, he does not love." The knout is to-day employed as a part of the punishment of those who are condemned to Siberia. These unfortunates, however, are not whipped in Russia; the sentence of the court provides that the blows, numbering from twenty-five to one hundred, shall be given in the prison in Siberia when the prisoner arrives. The Russian officials are ashamed of the barbarism of these sentences. Physicians should at all times refuse to sanction corporal punishment of criminals, and should refuse to give their official approval of such acts, because they are

contrary to the spirit of the Hippocratic oath. In Nicolaev the city council has recently asked the cab drivers of that city to abolish the whip as an experiment for three months. How can this be expected, when these drivers themselves may be whipped for petty offences, or even innocently, without hearing or trial before any court? Societies for prevention of cruelty to animals exist in Russia, and yet human beings are treated worse than the lower animals.

Injections of Cinnamate of Sodium in Tuberculosis. By Dr. L. A. Finkelstein.—The author has used these injections in twenty cases of pulmonary tuberculosis which were under his observation in a sanatorium during the entire length of the treatment. In addition to the injections, the usual dietetic and hygienic measures were applied. He used an aqueous solution of sodium cinnamate (containing 0.15 or 0.30 grammes in ten cubic centimetres), and the sites selected for the injections were the interscapular regions, the right and left side being used alternately. The solution was freshly prepared before the injection, and it was rendered sterile before using. The syringe was also sterilized by boiling in soda solution before using. The skin was washed with three-per-cent. carbolic acid before each injection. The injections were always given at two o'clock in the afternoon, every third day, and were followed by slight massage of the parts. (*To be continued.*)

American Journal of Obstetrics, December, 1900.

The American Girl of To-day. The President's Address before the American Gynecological Society, May, 1900. By Dr. George J. Engelmann.—The author in an exhaustive article considers the American girl and her environment, and more particularly the influence of modern education upon her functional development. He has presented conditions as they exist; and, that they are not what we have a right to expect, he attributes to a misdirected refinement of civilization—*ignorance of and disregard of the function*, the crushing out of every question of sex in the girl, who soon learns to ignore, conceal, and deceive. The first step towards betterment is knowledge—a *knowledge of woman's functional life*, its conditions and requirements; an understanding of its nature by physician, educator, and mother, by the girl herself, and to her it must come from the mother. Upon the mother the author would impress, that perfect development of the female function and maintenance of this function, once developed, in a healthy condition, are essential to perfect development of the girl and perfect health of the woman; that self-care, a well-regulated female hygiene, is the foundation of her well-being, and that it is the mother's first duty so to guard herself and so guard her daughter. The *educator* should give heed to the instability and susceptibility of the girl during the functional waves which permeate her entire being; emotional stimulus must be avoided, and decided concessions must be made to the depression, physical and psychological, the lessened inhibition and physiological control during the fluctuation of puberty and menstruation. Let the *physician* take care and guidance of the girl during the great waves of female life, those periods of increased susceptibility and of physiological intensification and depression; and such care is the first and essential step in preventive gynecology.

Accessory Adrenal Body in the Broad Ligament; Adrenal of Marchand. By Dr. Aldred Scott Warthin.—

Although Aichel's results need further confirmation, it is very probable that his view is the correct one, and that adrenal tissue is a normal constituent of the broad ligament. The practical importance of this is very great, not only to the physiologist and pathologist, but to the clinician and gynecologist as well. In Marchand's adrenals we have certain anatomical elements which may explain pathologic conditions of the broad ligament and testis heretofore enveloped in mystery. Many tumors and cysts of these regions, whose origin is now unknown to us, may be shown by future observations to be derived from these little organs.

The Treatment of Persistent Occipito-posterior Positions of the Vertex. By Dr. George L. Brodhead.—Prophylactic measures are important. Before labor has begun, where the membranes are intact and engagement has not taken place, it has been recommended by Reynolds to place the patient in the knee-chest position twice each day for the last two weeks of pregnancy, and then in the lateral position. By the use of this method, the position will almost surely become anterior. The conditions which should be fulfilled before the operation of rotation is undertaken are these: (1) the head should be as well flexed as possible; (2) the vertex should be well down in the pelvis and preferably at the vulvar outlet; (3) the membranes must be ruptured; (4) the cervix should be fully dilated or dilatable; (5) the bladder and rectum should be empty; (6) last, but not least, the operator should be positive of his diagnosis of position. The Tucker solid-bladed forceps are preferred by the author.

The Removal of Pelvic Inflammatory Masses by the Abdomen after Bisection of the Uterus. By Dr. Howard A. Kelly.—This article is an illustration of the author's procedure in a case, for example, *where there are pelvic abscesses on both sides, densely adherent to all the surrounding structures.* If the uterus is buried out of view, the bladder is first separated from the rectum and the fundus found; any large abscesses, adherent cysts, or hæmatomata are aspirated; the rest of the abdominal cavity is then well packed off from the pelvis. Each cornu is then seized by a stout Museau forceps, and, as the uterus is bisected, its cornua are pulled up and drawn apart. By keeping two forceps in constant use at the lowest point, the uterus is pulled up; the halves become everted. For a panhysterectomy, the bisection is carried all the way down into the vagina. If it is to be a supravaginal amputation, the Museau forceps are made to grasp the uterus well down in the cervical portion, and the cervix is bisected on one side. As the vaginal and uterine ends pull apart, the uterine vessels, which can be plainly seen, are clamped or tied. The round ligament is subsequently exposed and clamped, and finally a clamp is applied between the cornu of the bisected uterus and the tubo-ovarian mass, and one half of the uterus is removed. The opposite half is also taken away in the same manner.

A Case in which Sexual Feeling First Appeared after Removal of both Ovaries. By Dr. A. Laphorn Smith.

Remarks on the Technique in Dealing with the Pedicle in the Removal of Intrapelvic Growths and Structures. By Dr. Richard R. Smith.—The faults which are most usually committed, and which the author especially condemns, are these: (1) use of silk; (2) ligating tissues *en masse*; (3) leaving too short a pedicle.

A Case of Congenital Ventral Hernia. By Dr. Eustace L. Fiske.

Medical Chronicle, Manchester, December, 1900.

On Aseptic or Antimicrobial Medicine. By Dr. A. Ransome.—A presidential address.

Some Remarks on the Nature and Origin of Cancer-cells—A Contribution to the General Ætiology and Pathology of Malignant Disease. By P. R. Cooper, M. B.—The object of the present communication is to draw attention to the cellular changes which culminate in the formation of a malignant tumor, and also to point out the probable bearing of certain considerations which arise from the study of these changes, upon the general ætiology and pathology of cancer. It is fairly well established that the cancer-cells are directly derived from pre-existing cells of the body, but the direct conversion of a normal into a malignant cell has, however, never been seen under the microscope. The chief facts pointing to this conclusion are: 1. The cancer-cells bear a striking morphological resemblance to the cells which normally constitute the tissues of our bodies, or, to be more exact, to the *embryonic* condition of those cells. 2. The cells of the different kinds of tumors each present a special affinity for the normal tissue cells of the particular part of the body in which the "new growth" first appears. 3. It is possible to observe in tumors of varying degrees of malignancy clearly intermediate forms between the most extreme type of malignant cell on the one hand, and perfectly normal tissue cells on the other. 4. On careful examination the more or less abrupt transition between the normal and cancerous cells can be made out. 5. All secondary or metastatic growths correspond histologically with the primary growth, and therefore with the tissue of origin of the new growth proper, and the occurrence of the secondary growth can invariably be traced to the migration of cells from the primary growth along the blood or lymph channels.

The view most generally held is that the normal tissue cells become directly converted into cancer-cells, but the author inclines to the view that the adult tissue cells first undergo a process of reversion or atavism, whereby they are reduced to an embryonic or mother-cell condition, and it is from these secondarily embryonic or histogenetic cells that the true cancer-cells are formed. The author, from his observations extending over a period of six years, has been forced to the conclusion that the cancer-cells are formed from the histogenetic cells of the body, and are therefore most probably of a primary embryonic nature.

The typical cancer-cell resembles its embryonic prototype, and differs from the fully formed, functionally active tissue cell of the adult in the following chief particulars: (1) its generalized shape, which, although variable and irregular, inclines to be spherical; (2) its comparatively large nucleus, which (3) often exhibits evidence of division; (4) its more or less homogeneous protoplasm; (5) its large proportion of glycogen. It differs, however, from the normal histogenetic cell in (1) its mode of division (direct cell division and endogenous cell formation instead of orderly karyokinesis); (2) its power of movement or migration; (3) its power to englobe or ingest albuminous particles; (4) the frequent presence of certain "intracellular bodies" in its interior; (5) its proneness to undergo degeneration or necrosis, *i. e.*, its feeble resisting powers; (6) its abnormal metabolism, as evidenced by the production of certain toxins which affect the blood and injure the tissues generally.

In cancer the formation of new cells is apparently

without any definite order or direction. The cell increase goes on apparently unchecked, the great numbers produced forcing their way through the normal boundaries and invading the adjoining healthy tissues. In simple tumors, although an excessive production of cells occurs, they undergo adult development and never transgress the normal boundaries. In cancer the departure from the normal seems to be a permanent one. A consideration of the above-mentioned facts seems to warrant the conclusion that the essential change in malignant disease is the failure of development of the cells, and the fault can be primarily traced to the histogenetic cells of the body. Thus failure of development implies a breakdown of the normal "integrating mechanism" of the cells.

Of the causes that determine the departure of the cancer-cells from the healthy condition very little is known. The author holds that the cause of the loss of integrating power of the cancer-cells is congenital. Where the failure is absolute from the beginning of life, we have congenital or embryonic malignant tumors. In other cases the amount of integrating power is perhaps enough for ordinary circumstances but insufficient for any extra demands, and hence are explained cases of acute traumatic sarcoma occurring in early life. In the majority of cases, however, there is a sufficient amount of integrating power both for ordinary purposes and for considerable extra demands; but as age advances, the activity of the nuclear material declines, and at this period exceptional demands are not so readily met, hence the greater frequency of cancer in advanced age. Again, we can see how long-continued irritation, by keeping up cell proliferation and dividing up the nuclear material into minuter and minuter portions, gradually attenuates the integrating power until it is no longer capable of inducing cell development. The causes of long-continued irritation are well known, and amongst these, micro-organisms undoubtedly occupy a prominent place, but in admitting that parasites may in this way be the means of inducing a malignant tumor, we are far from arriving at the conclusion that a parasite is the specific cause, *i. e.*, the *sine qua non* of cancer.

Proceedings of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Twenty-second Annual Congress, Held (in Conjunction with the Congress of American Physicians and Surgeons) in Washington, on Tuesday, Wednesday, and Thursday, May 1, 2, and 3, 1900.

The President, Dr. SAMUEL JOHNSTON, of Baltimore, in the Chair.

(Continued from page 262.)

Tracheal Injections in the Treatment of Pulmonary Tuberculosis.—Dr. T. MORRIS MURRAY, of Washington, read a paper on this subject (see page 241).

Dr. WILLIAM E. CASSELBERRY, of Chicago: I have had some experience with tracheal injections in the treatment of pulmonary tuberculosis, laryngeal tuberculosis, laryngeal irritation, and bronchial inflammation of various types. As regards the technique of the procedure, it is perfectly feasible, especially with the use of a preliminary brief application by spray of a one- or one-half-per-cent. cocaine solution to the larynx. Pa-

tients tolerate the procedure very well indeed after the first or second treatment. They readily become accustomed to it, and the quantity of material that one can introduce into the larynx and trachea without much coughing and expulsion is sometimes astonishing. If we use oil as a menstruum, the material gravitates down the trachea and into the larger bronchial tubes, and possibly in some cases it may reach the smaller bronchial tubes. That there are suitable cases of tuberculosis, associated with secondary infection leading to profuse expectoration, with a good deal of laryngeal and tracheal irritation, which may be benefited by periods of treatment of this sort, there can be no doubt, as the reader of the paper has said, because it lessens the cough, reduces the fever, and conduces generally to the comfort of the patient. But I have no confidence whatever in it as a specific treatment for pulmonary tuberculosis. I think it is stating the case too strongly to maintain that there is much benefit from this method in the long run in cases of pulmonary tuberculosis. From our understanding of the pathology of tuberculosis of the lung, it does not seem plausible that either deep spraying of the bronchial tract or injections of this material can have much effect upon the tuberculous infiltration itself in the lung tissue.

Dr. J. SOLIS-COHEN, of Philadelphia: I have had considerable experience in the use of tracheal injections, dating back nearly forty years. I have had what is known as the Tobold syringe in my possession for nearly that length of time, but I have not always used the solutions that have been referred to. I can also testify that this treatment gives comfort in many cases. Persons with pulmonary tuberculosis feel a sense of comfort in the entire chest after this treatment, and the odor from the menthol is perceptible for a considerable time. I find the most marked benefit from this treatment in an entirely different condition, namely, bronchorrhœa. I believe it is the best remedy to use in this condition. You can use two or three injections twice, one after the other, and direct your applications to one side or the other. If you find that the remedy passes more into one side than the other, you can modify this. You will find in a short time that the secretion will be diminished by forty, fifty, seventy-five, or eighty per cent.

Dr. J. E. LOGAN, of Kansas City: I wish to corroborate what Dr. Casselberry has said with reference to this treatment in pulmonary tuberculosis. I have used tracheal injections with a good deal of success in certain forms of pulmonary diseases, but my experience has not been favorable in the treatment of phthisis. However, my experience in these cases has been limited, and I can understand how it might be possible to afford tuberculous patients great relief at certain stages of the disease. The best results I have had have come from its use in treating cases of bronchitis and bronchorrhœa attended by asthmatic symptoms, and also patients suffering from hay asthma.

I recall a case treated some three years ago, one of bronchiectasis, in which I had a good result. The patient is well, and at least comfortable, at the present time. In cases of bronchorrhœa with excessive secretion, I believe the local application of medicines to the part is apt to be more beneficial than the roundabout way we have of administering them through the general system.

Dr. A. W. DE ROALDÈS, of New Orleans: I have also had some little experience with these tracheal injections. In the treatment of tuberculosis of the lower

air-passages and of pulmonary consumption, beyond a slight temporary improvement, as in the case of other new medications, I cannot say that I have obtained sufficient material benefit to justify me in adopting this method as a standard form of therapeutics.

I recall a case, however, of a very prominent man whose ill health was for several years attributed by different observers to pulmonary consumption, while he himself attributed his sickness to chronic malarial toxæmia. Emaciated and weak, he complained of fever, cough, expectoration, etc. The microscope and a closer study of the symptoms finally cleared up the case, which was diagnosed as one of bronchiectasis and treated by me with these tracheal injections. The improvement was a surprising one, as after eight or ten injections the patient acknowledged he had not felt so well in many years. These injections had a manifest effect on the temperature, cough, and expectoration, and were instrumental in happily modifying these symptoms, at different periods of his illness, of which he finally died ten years later.

Dr. MURRAY: In replying to some of the remarks of Dr. Casselberry, I would state distinctly that I do not wish to be understood as having intended to convey the impression that I expected to cure patients who had tuberculosis with intratracheal injections. I do think, however, that if we can reduce the temperature in these cases, if we can lessen the cough so that the patient's rest is not disturbed, if we can increase the appetite, we certainly have a valuable aid to any other treatment which may offer possible curative results, particularly the climatic treatment.

With reference to the influence exerted upon these cases described by Dr. Roaldès and Dr. Logan, my own experience has been exactly the same. My results have been best in cases of bronchorrhœa. One of my cases, which I did not mention in the paper, treated as a case of tuberculosis at first, was such a case. The patient's condition was wretched. Examination disclosed what was supposed to be an involvement of the left apex, but, inasmuch as the man got entirely well, and the microscope did not confirm the diagnosis, I excluded his case from this list.

(To be continued.)

Book Notices.

BOOKS, ETC., RECEIVED.

Operative and Practical Surgery. For the Use of Students and Practitioners. By Thomas Carwardine, M. S. (Lond.), F. R. C. S., Assistant Surgeon, Bristol Royal Infirmary. With 550 Illustrations, most of which are Original Drawings by the Author. Pp. xx-661. Bristol: John Wright and Company, 1900.

Infant Feeding in its Relation to Health and Disease. By Louis Fischer, M. D., Attending Physician to the Children's Service of the New York German Poliklinik, etc. Containing 52 Illustrations, with 23 Charts and Tables, mostly Original. Pp. viii-359. Philadelphia: F. A. Davis & Company, 1901.

The Students' Manual of Venereal Diseases. By F. R. Sturgis, M. D., Sometime Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York, etc. Seventh Edition, Revised and in Part Rewritten by F. R. Sturgis, M. D., and Follen Cabot, M. D., Instructor in Genito-

urinary and Venereal Diseases in the Cornell University Medical College, etc. Pp. xii-17 to 216. Philadelphia: P. Blakiston's Son & Company, 1901.

Diseases of the Anus and Rectum. By D. H. Good-sall, F. R. C. S. (Eng.), Senior Surgeon to the Metropolitan Hospital, etc., and W. Ernest Miles, F. R. C. S. (Eng.), Assistant Surgeon to the Cancer Hospital, Brompton, etc. In Two Parts. Illustrated. Part I. Pp. 311. London, New York, and Bombay: Longmans, Green & Company, 1901.

The History of Ancient Gynæcology. By W. J. Stewart McKay, M. B., M. Ch., B. Sc., Senior Surgeon to the Lewisham Hospital for Women and Children, Sydney, etc. Pp. xx-302. New York: William Wood & Company, 1901.

The History of Medicine in the United States. A Collection of Facts and Documents relating to the History of Medical Science in this Country, from the Earliest English Colonization to the Year 1800. With a Supplemental Chapter on the Discovery of Anæsthesia. By Francis Randolph Packard, M. D. Illustrated. Pp. 5 to 542. Philadelphia and London: J. B. Lippincott Company, 1901.

Transactions of the Royal Academy of Medicine in Ireland. Volume xviii.

Report relating to the Registration of Births, Marriages, and Deaths in the Province of Ontario. For the Year ending December 31, 1899.

Sixteenth Annual Report of the New York Post-graduate Hospital. For the Year ending October 1, 1900.

Thirty-third Annual Report of the New York Orthopædic Dispensary and Hospital. From October 1, 1899, to October 1, 1900.

Reports of the Trustees and Superintendent of the Butler Hospital for the Insane. Fifty-seventh Annual Meeting, January 23, 1901. Providence, Rhode Island.

Fiftieth Annual Report of the Demilt Dispensary, in the City of New York. For the Year 1900.

Fourteenth Annual Report of the Children's Free Hospital Association. Detroit, Mich.

Twenty-eighth Annual Report of the State Charities Aid Association to the State Board of Charities of the State of New York. November 1, 1900.

Miscellany.

A Phagedænic Chancre Rebellious to Mercury.—Dr. W. J. Collins (*Lancet*, January 5th) reports the case of a young woman, aged nineteen years, a domestic servant, of healthy appearance, with a tuberculous history on her mother's side, who was admitted into the London Temperance Hospital on February 27, 1900, with an ulcerated swelling in the prolabium of the upper lip. The base of the ulcer, which was of trefoil shape, was hard and infiltrated, giving in profile the appearance of a conical projection. The surface of the ulcer secreted a little thin encrusted pus and the edges were sharply defined against the red mucocutaneous surface of the labium. There were enlarged and tender glands below the mandible, more pronounced on the left side; the preauricular lymphatics were unaffected. Dr. Collins made a provisional diagnosis of a syphilitic chancre and ordered mercurial inunctions.

On March 21st the ulceration was noted to be slowly extending and the appearance was that of a phagedænic ulcer destroying the tissues of the lip. An examination

of the blood for organisms gave a negative result. On the 24th the appearance of the ulcer was described as "crateriform." The temperature continued to be elevated, ranging between 99° F. and 100° F. and occasionally reaching 101° F., and there was much pain in moving the lip; otherwise there were no constitutional symptoms. On April 5th an ulcer appeared on the left tonsil, and on the 12th this had extended to the left side of the palate. Despite full doses of mercury externally and internally, the condition of the lip was becoming worse rather than better, and the patient's condition was very deplorable. Ophthalmoscopically, no change was to be seen and no eruption appeared on the skin.

On May 10th Dr. Collins decided to give up mercury in favor of large doses of iodide of potassium. An improvement was soon apparent in the lip, though the palate showed a sloughing appearance. The submaxillary glands became reduced in size and were no longer tender. On May 19th the edges of the ulcer on the upper lip were becoming healthy and a slough had separated. On the 28th there was rapid improvement. Some deformity of the upper lip resulted. The throat was still ulcerated. On June 19th the lip was well and the throat was rapidly healing. There were no skin or ocular symptoms. Her general health was greatly ameliorated. On the 22d the patient was discharged, apparently well. She was ordered to continue the iodide of potassium for a while and to return later for plastic operation on the lip. Six months later the patient was well and the deformity was much less noticeable.

Dr. Collins remarks that the occurrence of phagedæna in a syphilitic sore is to be attributed probably to a secondary local inoculation with a septic organism and not merely to a debilitated condition, which cannot be its sole cause, since when more than one syphilitic ulcer is present some become phagedænic while others often undergo no change. In the case reported, no explanation of the source of infection was forthcoming, though it is difficult to doubt the nature of the disease. The extensive phagedæna, the early implication of the throat, the absence of any skin eruption, the rebelliousness to mercurial treatment, and the rapid improvement under potassium iodide are noteworthy features in the case.

Death by Falling from a Height not Painful.—According to the *Medical Review* for January, Professor Heirn, the geologist of Zurich, an ardent Alpine climber, stated recently in a lecture that life contained few experiences more agreeable and enjoyable than falling over a precipice or slipping into a glacier crevasse. Even the landing after the fall was free from anything of pain or terror. Merely a jar and then unconsciousness. Professor Heirn first cited the sensations described by a Swiss climber, who fell from the top of the Karpfstock, in Switzerland:

"The plunge, which was taken backward, was in no wise accompanied by the anxiety felt when one dreams of falling. I seemed to be borne in the most pleasant manner gently downward, and had complete consciousness during the entire fall. Free from all pain or fear, I contemplated my position and the future of my family, which I knew was assured by the insurance I carried. And this contemplation was accomplished with a rapidity which I had never before known. Of the losing of my breath, of which people talk, there was no suggestion, and only the heavy fall on to the snow-covered ground caused me to lose suddenly and painlessly all consciousness. The bruising of my head and limbs on the rocks as I fell caused me no pain. The reawakening, however,

brought with it entirely different and far less agreeable sensations."

Of his own experience of the sensations of falling, Professor Heirn said: "As soon as I stumbled I saw that I should be dashed over the rock, and awaited the shock. I dug my fingers into the snow in the endeavor to stop myself, but merely tore open my finger tips, causing them all to bleed, but feeling no pain from so doing. I plainly heard the striking of my head and back against the rock, and the thud when I landed. Pain, however, I did not feel until half an hour later, when I revived. During the fall came a flood of thought. Every thought and impression was clear, in no wise dreary and confused, and was logically connected with the one which followed. First, I contemplated the probability of my fall, and said to myself: 'The rock over whose edge I shall be dashed evidently descends sheer, for I cannot see the ground on the other side. It becomes, therefore, a question whether or not there is snow at the foot. If so, the snow will be melted near the wall and will form a ledge on which I shall land, and thus escape with my life; if not, then I shall strike on rocks below and death will be unavoidable. If I am not killed and am not unconscious, I must at once take out my little vial of liquor, and drink a few drops of it. My alpenstock I must hold on to, for it may prove of use.' I thought that I should take off my snow glasses and throw them away, for fear they might be broken and the splintered glass get into my eyes; but the position in which I was falling prevented my moving my hands sufficiently to do this. Another train of thought busied itself with the effect my fall would have upon my companions. I said to myself that when I landed, no matter whether I was hurt or not, I must, if possible, call out with all my might, 'I am in nowise injured!' in order that my comrades might rouse themselves from their terror and be able to make the difficult descent necessary for the bringing of assistance to me. I also thought that I should not be able to deliver the lecture which five days later was to mark my entrance into the professorship. I realized how the news of my death would shock my family, and in thought tried to console them.

"Then I saw, as if upon a stage, my entire life pass like a series of tableaux before me. I saw myself as the chief actor. Everything seemed glorified as by some heavenly light, and all was beautiful and free from pain, from anxiety and sorrow. Even the memory of sad events was distinct, but not sad. Exalted and beautiful thoughts dominated and connected the single scenes, and a divine quietude sank like sweet music into my soul. Ever more and more plainly I felt myself surrounded by a heaven of glorious blue, filled with clouds of rose color and of violet. I sank gently and painlessly into it, and saw that I was flying through the air toward a field of snow. Objective observations, reasoning, and subjective feeling were indulged in clearly and simultaneously. Then I heard a dull thud, and my fall was ended. At the same moment it seemed to me that a black object rushed by me, and I called two or three times as loudly as I could: 'I am in nowise injured.' I took some drops of the liquor, I reached out for my snow glasses, which lay unbroken beside me on the snow, I felt my back and my limbs to see that no bones were broken.

"When I struck I lost consciousness. Every sensation, every activity of mind and nerve was annihilated for a half hour. The black object which passed me was the passing of consciousness. And, without realizing this half-hour interruption, thought and activity were resumed exactly where they stopped. Between the stop-

ping and resuming was an absolute blank. The beautiful heavenly visions were noticeable only during the time that I was flying through the air, and could see and think."

Professor Heirn said at the close of his lecture that death by falling is subjectively a pleasant death. Without any previous illness or suffering, it occurs when one is fully conscious, when mental activity is abnormally increased and without any anxiety or pain. The unconscious state is entered suddenly and without suffering.

An Unattached Specialty.—The ancient Egyptians were evidently a point or two ahead of us in other things besides pyramid-building. What says Herodotus (Euterpe, lxxxiv)? "The healing art is thus practised among them. Each physician confines himself to one disease, not more. There is an abundance of physicians. Some of them devote themselves to the eyes, some to the head, some to the teeth; others again to the bowels, and still others to more obscure disorders." It is true that in the present day we are once more approaching their level, but even now our specialization is far from complete. The *Lancet* for February 9th quotes the following amusing verses by "J. B." from the *St. George's Hospital Gazette*, detailing the woes of a titled invalid in search of an appropriate specialist:

A tumor he developed on
A spot that's quite neglected;
No specialist for just that point
He anywhere detected.

So curiously was it placed,
That, search from toe to crown,
You saw it not when he stood up,
Still less when he sat down.

From day to day the swelling grew,
So vast became that tumor,
You could not say which was the growth
And which Sir Francis Boomer.

And so at last it finished him,
Despite his numerous staff,
And he explained the cause of death
In this his epitaph:

"My ailment could not treated be,
The times were out of joint;
There was no specialist upon
The Perineal point.

"Some doctors find their work before,
And others theirs behind,
But none devotes attention to
The spot which I've defined."

The Amended Bell Bill.—The following are the terms of this measure as reported favorably on the 14th inst. to the Assembly:

"Any person shall be regarded as practising medicine who shall for remuneration, charge, fee, gift, bonus, or reward, directly or indirectly, profess to heal, or who shall give treatment to any other person by the use of any means or method whatever, whether with or without the use of any medicine, drug, instrument, or other appliance, for the relief or cure of any wound, fracture, or bodily injury, infirmity, physical or mental, or other defects or diseases.

"This article is not to apply to any person giving

treatment to another under the direction or upon the prescription of a physician, duly licensed by the laws of this State. Neither is it to prohibit the manufacture, sale, or use of patent medicines where no diagnosis is made by the maker or seller, or the giving temporary relief in an emergency by a registered pharmacist or any person, or the domestic administration of family remedies; or any person in charge of or employed in any gymnasium from giving suggestions or advice as to form or methods of exercise, or any optician engaged in adapting glasses to the sight, or any rights of chiropodists under existing laws, or the manufacture or construction of optical instruments."

The Psychoses of Puberty.—The *Journal de médecine de Paris* for December 30, 1900, gives three reports on this subject by M. Marro, of Turin; M. J. Voisin, and M. Ziehen, respectively.

M. Marro's Report.—At the period of puberty there is in the two sexes an association of special conditions: increase in the form, development of sexual characters, modification of the voice, growth of hair on the body and of beard in the man, and development of the breasts in the woman. Also the following biological conditions: Development of the capacity for generation, appearance of menstruation, an arrest of the amount of carbonic acid eliminated in respiration and of urea in the urinary secretion, and, in the young man, an increase of vital capacity; growth of emotiveness, and development of new instinctive and affectional impulses.

The immediate consequences of these modifications lie in metabolism, the rapid disappearance of the circulation of albumin and salts, the temporary lessening of the total general resistance, which produces, in the psychological sphere, troubles of conduct and the moral life, all the graver if a preceding weakness from morbid heredity or acquired diseases has rendered the organism less resistant. The effects of the sexual impulses which awaken at this period and from lack of inhibitory power are dangerous, may lend its increment to the dangers and effects of other predisposing causes.

It is in virtue of these conditions that congenital morbid states acquire at this time a gravity and intensity previously lacking, and that from this age many dispositions that reflect themselves in later life take their rise.

Among the psychoses of puberty, hebephrenia may be regarded as specific. Its morbid manifestations and microscopical changes demonstrate that the cerebral cortex and the meninges are the seat of an anatomical morbid process. The symptoms of invasion tend to prove that the cause may be referred, with some probability, to a process of self-intoxication from troubles of the intestinal tract.

M. Voisin's Report.—These psychoses constitute the mental affections that develop from fourteen to twenty-two years of age, a period characterized by sexual maturity and the physical and intellectual development of the individual. Every variety of psychosis may show itself: hebephrenia, as a morbid entity, has no existence, and this term should be reserved for cases of dementia. The psychoses that develop at the beginning of the puerperal evolution are less grave than those that develop in the course, or at the termination, of puberty.

Hereditary predisposition is the predominating cause of these affections; it is the association of complete intellectual development with heredity that gives to the complaint its so-called hebephrenic stamp. Melancholia appears most often in the grave form of stupor, and may be accompanied with mysticism and masturbation.

Mania frequently assumes the characters of moria ["a variety of delirium characterized by imbecility, unreasonableness, or shallowness"], and presents also many impulsive characters. Previous dementia, or hebephrenia, occurs under a grave form, with stupor or catatonia, and a light form or simple precocious dementia, which must be distinguished from general paralysis and from spasmodic epileptic dementia.

Mental confusion presents a delirium of dreams having great analogy with alcoholic delirium; it characterizes the psychoses of self-intoxication, brought about by troubles of nutrition. A cure is attained in about half the cases, and is accompanied by retrogressive and progressive amnesia.

General juvenile paralysis is distinguished from that of the adult by the absence of grandiose ideas and its slower progress. The degenerative psychoses and the neuropsychoses are the most frequent, and reappear generally at adult age.

From a medicolegal point of view [French], no account need be taken of the subject's civil capacity, which does not exist until twenty-one years, while the criminal responsibility begins at sixteen years.

M. Ziehen's Report.—The hereditary taint determines at puberty a greater morbidity. Outside of this, anæmia, bodily and mental overstrain, acute infectious diseases, and sexual excesses play a part. Nearly all the known psychoses are met with at this time, but certain ones especially prevail and show special modifications in both their symptoms and their course. A psychosis special to puberty, and of frequent occurrence, has been erroneously spoken of; the only special one, hebephrenic dementia, furnishes but a small number of cases.

The most frequently observed are: cyclical insanity, mania, melancholia, acute hallucinatory paranoia, and insanities of hysterical or epileptic foundation, and outside of these, the following modifications: Exaggerated weakness of the affective troubles, a discordance between these troubles and mimetic reactions, some incoherence of delirious or normal ideation, the illogical, trivial, and fantastic character of the ideas of delirium, and a tendency to a cyclical course, or to a progressive dementia.

For these reasons, the prognosis in general is worse than that of post-puberal psychoses. There is nothing special in the treatment. Total confinement to bed is only admissible when there is pronounced exhaustion. Regular occupation, both physical and mental, regulated for every hour of the day, is important in most cases. The employment of narcotics should be restricted as much as possible. Great care must be exercised in choosing adult patients with whom pubescents are to be associated in a common ward.

A New Test for Bile.—Professor E. H. Bartley, M. D. (*American Druggist*, March 11th), says that the use of ferric chloride and hydrochloric acid as an oxidizing agent is well known, and is resorted to in the detection of indoxyl in the urine. The method of its use for this purpose is to add to the urine an equal volume of strong hydrochloric acid and then a few drops of the ordinary test solution of ferric chloride. The potassium indoxyl-sulphate is thus decomposed, and the indoxyl is oxidized to indigo blue. The indigo is dissolved out of the solution by shaking with about two cubic centimetres of chloroform, in which it is soluble. As the chloroform separates, it carries down the indigo and forms a blue indigo-chloroform layer at the bottom of the test tube.

If this same test is applied to a urine containing bile coloring matters, the solution assumes, on adding the ferric chloride, a beautiful emerald-green color. This green coloring matter is insoluble in chloroform, and hence does not interfere with the indican test. Bile and indican can therefore be tested for at the same time and in the same solution. The test was first observed by the author in examining fæces, and the test was made as follows: An alcoholic extract of the fæces was made and filtered clear. To this alcoholic solution hydrochloric acid was added and then a few drops of ferric chloride solution. An intense green color was immediately produced. This reaction has been tried upon a great many specimens of urine and no sample not containing bile has been found to give a green color. He believes it to be the best, the most characteristic, and the most delicate test we possess for the presence of bile in urine or fæces. He has not been able to find in the literature any mention of this process for the detection of bile, although it seems strange that it has not been mentioned, as the reagents are commonly used together in the test for indican.

Whistling Spells Following Brain Injury.—Dr. William Krauss (*Journal of Nervous and Mental Diseases*, January) describes the case of a Polish herdsman, twenty-seven years of age, weighing 230 pounds, who, some months previous to an accident, had suffered from apoplexy resulting in left hemiplegia. He was slowly regaining the use of his arm and leg, when he was struck by a train, and was found unconscious on the track with three scalp wounds. There was a depressed fracture of the skull three inches above and one inch behind the left ear. No other important injuries were found. He was immediately trephined and the depressed bone removed. It was found necessary to strap his arms, as he constantly tried to remove the bandages with his right arm or waved it up and down, not resting quietly. There was complete loss of control over the bladder and rectum, no increased temperature; pulse slightly lowered. He was put on milk diet and given stimulants in abundance.

About ten o'clock at night he began to whistle, not, however, the "popular songs of the day," but the whistle calls he was accustomed to use in calling or driving his flocks. He would continue whistling for about one minute, then would cease for five or ten minutes, and kept this up at regular intervals until he died, January 3, 1899, at 10.30 P. M. At no time was it possible to distinguish any melody. The sounds were of the same pitch and intensity and of the same character. They were audible throughout the ward and attracted the attention of patients and attendants. To the physicians in attendance it was a strange experience to hear these whistle calls coming from a patient in a state of unconsciousness. It was impossible to rouse the patient at any time before or after the accident, and he died, whistling a few minutes before death.

Fœtal Rhachitis.—Dr. F. Fede, director of the Clinical Institute for Diseases of Children of the Royal University of Naples, and his assistant, Dr. G. Finizio (*Revue mensuelle des maladies de l'enfance*, March), conclude from their investigations that fœtal rhachitis is very rare, which conclusion they consider established on a sound basis by their microscopical researches. From these they feel justified in stating that large fontanelles and widely separated sutures in the newly-born are not always indicative of rhachitism, and that in most cases they imply simply retarded ossification.

Original Communications.

CONGENITAL DISLOCATION OF THE SHOULDER, WITH REPORT OF TWO CASES OF DISLOCATION POSTERIORLY.

By DANIEL W. MARSTON, M. D.,

NEW YORK,

INSTRUCTOR IN ORTHOPÆDIC SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; VISITING SURGEON TO THE RANDALL'S ISLAND HOSPITAL.

(Concluded from page 445.)

One of the illustrations shown is that of a baby suffering from obstetrical paralysis. I exhibit it in this connection to show the almost exact similarity of the position of the paralyzed limb and of the arms in the cases of congenital dislocation of the shoulder. In these cases no operative measure is indicated. In my opinion, at least fifteen per cent. of the cases of so-called obstetrical paralysis can be proved to be instances of congenital dislocation, and can be greatly benefited by the operation I have described.

The prognosis in this dislocation is even better than in congenital dislocation of the hip.

Küster's case, operated upon before the days of antiseptic surgery, resulted fatally, from what reason he does not state. All of the other cases that I have been able to trace have been much benefited by the operation, and in nearly every instance the results have been brilliant. In Scudder's cases nothing was done; and, in these two of my own, the parents of the patients, having been repeatedly advised that the cases were incurable, are still loath to leave their children in the hospital for operative treatment.

The number of cases thus far reported as operated upon, with the names of the respective surgeons, are, so far as I am able to find:

Phelps, since April, 1895, four cases.

Eve, since August, 1895, one case.

Küster, one case, fatal result.

Stimson, one.

Post, one, 1881.

Gerster, one.

Schede, one.

Stone, one.

Gaillard's case was reduced without operation. Phelps has also had two cases of this sort, in infants, in which the reduction was performed under an anæsthetic, without resorting to the knife.

In those cases which are found reducible without operative procedure, the reduction can, so far as I have observed, be easily maintained by appropriate dressings of adhesive plaster. I can, however, readily see that, in cases where destruction of a part of the joint has occurred from disease, this might be difficult, as was the case with Gaillard's patient. Such cases should be operated upon. In stating the conclusions that I have drawn, I will say:

I. It is of the utmost importance to distinguish between cases of dislocation and true obstetrical paralysis.

II. The treatment of the former condition is immediate reduction; by manipulation if possible, otherwise, operative.

III. Every infant should be carefully examined at birth, for it is at this time that reduction is easiest performed.

IV. From the facts that a fracture of the glenoid cavity was found in three of Dr. Phelps's cases, and that the history of nearly all cases shows difficult labor, I am led to believe that these cases are not of paralytic origin, or due to non-development, as affirmed by Scudder, but

FIG. 12.—Patient suffering from true obstetrical paralysis. No operation indicated. Picture shows the similarity of this deformity to those of congenital dislocation.

are due to traction made in the axilla by the finger or vectis, or to the arm being caught in some unusual position and dislocated by the contraction of the uterus. Paralysis may be coincident, but it cannot be a primary factor in causing dislocation posteriorly.

V. The prognosis of the operative treatment is excellent. The earlier the operation the more hopeful the outlook.

FIG. 11.—A Röntgen picture of a case of congenital dislocation of the shoulder, afterward operated upon, in which a fragment of glenoid border was found attached to the capsule, demonstrating trauma as the cause of the deformity.

FIG. 13.—Third case of Phelps before operation.

FIG. 14.—Third case of Phelps after operation. Can place hand to mouth.

VI. Like congenital dislocation of the hip, these cases of the shoulder are little benefited by mechanical treatment. •

In connection with the description of the operation here advocated for this deformity, I wish to present for your examination the new excavator of Dijon, which will be found almost indispensable in the process of cleaning out the glenoid cavity for the reception of the head of the humerus. It is also of value in the open operation for the reduction of congenital dislocation of the hip. The instrument is made in three sizes, and consists of a cylindrical steel tube, conical at one end, furnished with

FIG. 15.—Phelps's third case, patient viewed posteriorly (after operation).

cutting edges like the old-time pot auger used by carpenters. These instruments leave the glenoid cavity with perfectly smooth and regular edges.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

BY NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

NEW YORK,

VISITING SURGEON, POST-GRADUATE HOSPITAL.

(Continued from page 500.)

Diseases of the Chorion.—The chorion and the amnion are essentially foetal envelopes, and, before considering the various derangements of these membranes, a short description of their formation and relation may be desirable.

The chorion is the outermost of the foetal membranes and is developed from the fusion of the zona pellucida, the false amnion, and the allantois, from which it derives its blood supply. When the ovum begins to form, the vitelline membrane becomes very much attenuated and gradually blends with the outer layers forming the future chorion. In the formation of the amnion there are two layers formed from the reduplication of the mesoblast and epiblast. The innermost of these, and the one which surrounds the embryo, is the *true amnion* and forms the *amniotic cavity*. The other is known as the false amnion, and lies adjacent to, and eventually becomes blended with, the internal surface of the zona pellucida. (Plate I, 1-6; and Fig. 1.) The chorion in an early period of gestation is covered over on its external surface with innumerable small cellular processes. These are the villi which soon become so important in the nourishment of the embryo. At first they cover the whole surface of the chorion. When, however, the young placenta begins to form, that part of the chorion which participates in its development takes on a greater activ-

ity, so far as the villi are concerned, but in that part that is not concerned in the formation of the placenta, the villi cease growing and eventually almost entirely disappear. (See Plate II, Figs. 1 and 2.)

In the human embryo, the umbilical vesicle is important during the earliest periods of development, as it is from this organ that the ovum derives its nourishment. When the allantois becomes developed, the umbilical vesicle retrogrades, and the allantois assumes the function of supplying the ovum with the necessary nutriment. This in turn is succeeded by the placenta as the nourishing medium.

At birth it is difficult to distinguish these various

The chorion occasionally takes on a peculiar pathological condition, and one that has received considerable attention. In this affection, and at varying intervals during pregnancy, small cysts are found coming away from the uterus. It is usually called hydatid, cystic, or vesicular degeneration. Just how frequent this disease is, we are not in a position to say. Judging from reports, it is more common than is generally believed. Most physicians who have a large midwifery practice have encountered it. There are various stages and degrees of this affection. Sometimes the condition may pass unnoticed. As the cysts come down the uterus they may be so pressed upon that they rupture and their con-

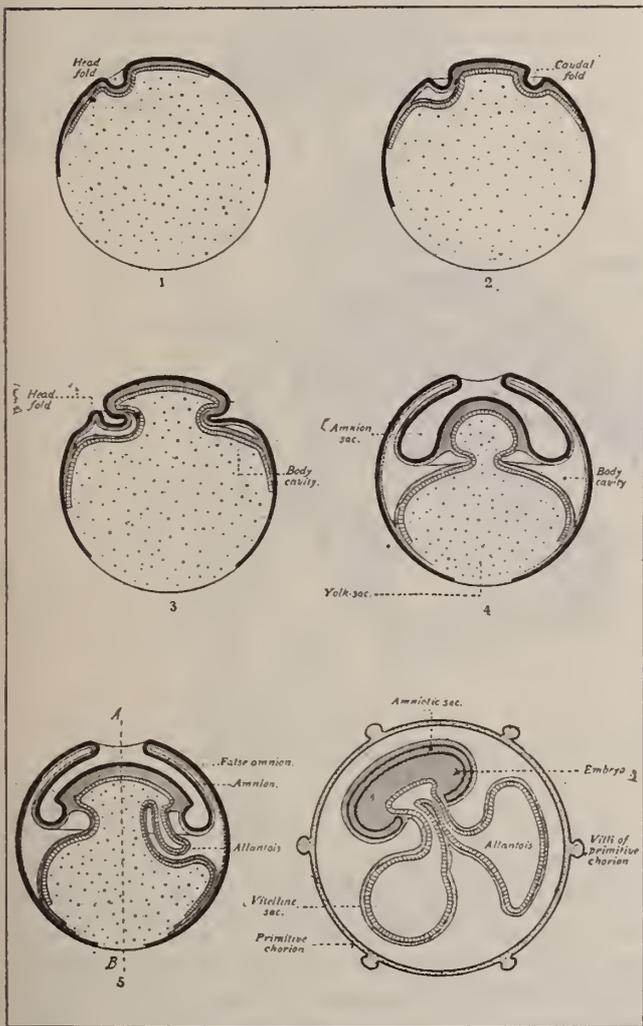

PLATE I.—Diagrams illustrating the formation of the mammalian fetal membranes (modified from Roule).

membranes from one another. They are intimately blended together by the gradual pressure of the amniotic fluid. This fluid gradually increases in quantity, and by about the end of the sixth month it has pressed the amniotic sac everywhere against the chorion. The chorion in turn presses against the decidua reflexa, and this decidua, from the constant and increasing pressure, is, in turn, forced against the decidua vera. By the end of gestation all these membranes are united into one.

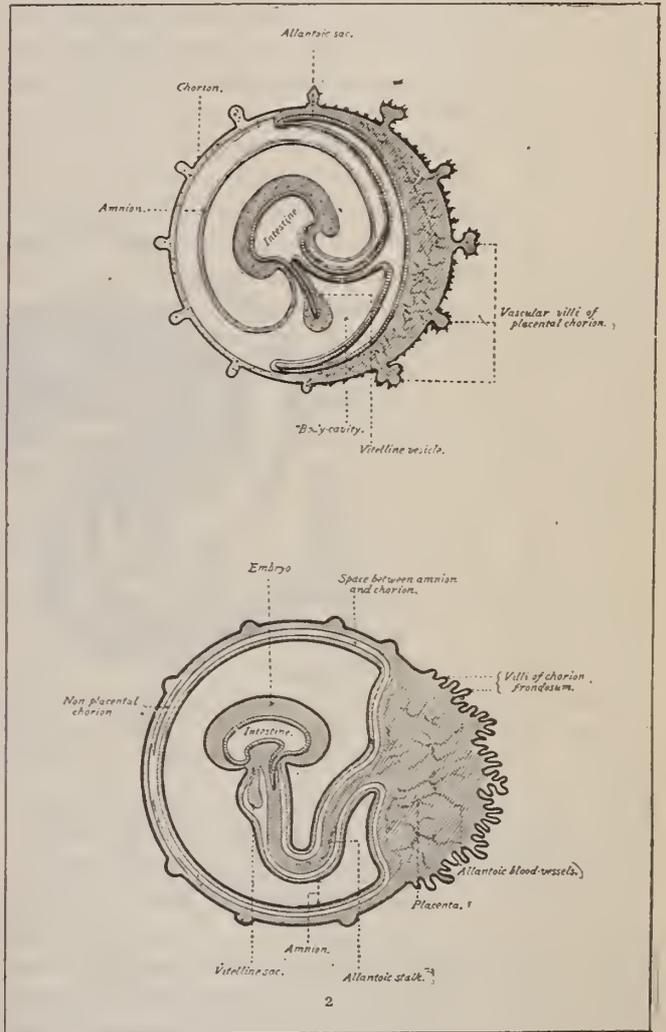

PLATE II.—Diagrams illustrating the later stages of the formation of the mammalian fetal membranes (modified from Roule).

tents alone escape. Between this, and the expulsion of so large a quantity of cysts as to fill a large basin, there are all degrees. The size of these vesicles varies from that of a pea to that of a large grape. In appearance they resemble a bunch of grapes, although each vesicle does not possess an independent pedicle; occasionally they are found attached to one another, but some of them at times have independent stems. (See Fig. 2 on p. 535.) The name uterine hydatids was given to this discharge

a long time ago under the belief that they were genuine hydatids. We now know that they are not echinococcus cysts, but the name still clings to them. By many of the older writers these bunches of enlarged villi were taken for small ova, and strange opinions of them were frequently entertained. Paré, who was reckoned one of the eminent authorities of his day, was one of these. In his *Surgery* he relates that the Countess Margaret, daughter of Florent IV, on Good Friday of the year 1276, gave birth to 365 immature children. Of this number, 182 were said to be boys, 182 were girls, and the odd one was an hermaphrodite. They were all solemnly baptized, the boys by the name of John and the girls Elizabeth. What name was given to the supposed hermaphrodite is not recorded. For a long time this delusion was accepted, but there is now no doubt that these immature infants were nothing more than 365 large cysts of a diseased chorion.

No disease of the foetal membranes has received so

there was a true hypertrophy of the main elements of the villi with œdema of the terminal bulbs. So it remained until the talented and celebrated Virchow investigated the subject with characteristic energy and accuracy. He announced that the difficulty that had existed in coming to accurate deductions on this important question was owing to lack of information as to the real character of a normal chorionic villus. He pointed out that these villi were composed of two entirely different parts—an outer covering, consisting of an epithelial covering, and a body which was composed of mucous tissue. In discussing this subject, it must be remembered that during the development of these villi, and for a certain time afterward, they are not supplied with blood-vessels. After they mature, small blood-vessels zigzag their way in and around them like webs. It is probable that at no time does any important change take place in the epithelium. It is in the body of these villi that pathological changes take place. As already stated, this is composed

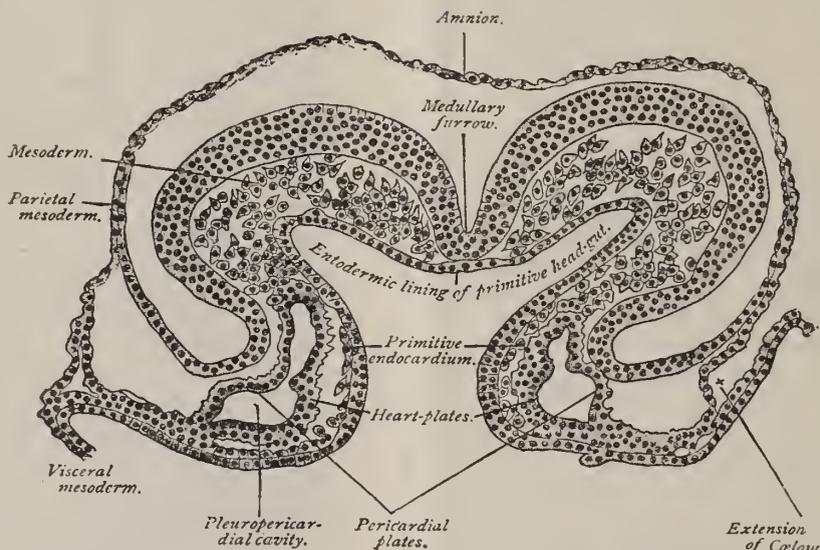

FIG. 1.—Transverse section of a sixteen-and-a-half-day sheep-embryo (Bonnet).

much attention as those of the chorion, and many excellent monographs have been published upon the subject. All the modern authorities seem to be in unison as to the morbid pathological processes that give rise to this peculiar disease. They regard it as arising from some kind of derangement of the villi. Occasionally, even now, a writer is found to lapse back to the old hydatid theory, and to regard the bladder-like cysts of the chorion as true acephalocysts; but it has been clearly demonstrated that these cysts possess none of the characteristic hooklets of the true hydatids. For a time after the hydatid theory of these growths was exploded, pathologists regarded these minute structures as due to the accumulation of cystic fluid within the villi. It was Velpeau who first maintained that they should not be considered as genuine vesicles. His opinion of them was that they were enlarged chorionic villi, and that their terminal extremities became swollen and club-shaped by distention from fluid. Others clung to the theory that

of mucus, and very probably this mucus will be found to be similar to that in the gelatin of Wharton in the cord. Priestley's investigations confirm the theories advocated by Virchow. He pointed out that these cysts were not mere dropsical swellings of the villi, but that the secretion that caused the distention came from very thin-walled cells in the centre of the villi. The results of a minute microscopic examination are here reproduced, in his own words: "Placing a terminal branch under the microscope, which seemed to the naked eye nearest to the normal condition, it was seen to be enveloped by a granular covering, probably derived from the altered decidua; the club-shaped extremities were observed to be distended with large nucleated cells, and bearing little resemblance to the small and more uniform cellules composing a terminal villus in a healthy state. By compression the envelope bounding the villus could be ruptured and gave egress to the cells. The fully developed cysts had two coats, like a normal

villus, the external epithelial, the internal delicately fibrous, but firm and dense. An incision being made through these, what appeared to be a viscous or gelatinous fluid escaped from the aperture, and this was found to be contained in large, transparent cells, with walls of extreme tenuity, assuming the polyhedral form from the pressure to which they had been subjected. The entire contents had much the appearance of the vitreous humor of the eye, which has transparent partitions running across, separating the fluid into compartments; the presence of a nucleus, however, in each compartment clearly proved it to consist of largely developed thin-

FIG. 2.—A portion of cystic chorion as seen with the naked eye. The arrangement of the vesicles is seen and also their attachments to the chorion membrane (Ercolani).

walled cells. The narrow stems uniting the cysts were fibrous, with cellular covering, and sometimes enclosed a small vessel full of blood. Fat granules were copiously deposited in the texture of both stems and vesicles."

Ercolani, whose researches on this subject are well known, disagrees entirely with both Virchow and Priestley as to the pathology of cystic chorion. He does not believe in its myxomatous origin and he disapproves of the appellation. He does admit, however, that he coincides absolutely with those who assert that a villus is composed of two parts, but he believes that the parenchymatous, or internal portion, loses its outer, or epithelial, covering just so soon as the villi become embedded in the decidua. From some perversion or pathological condition, this epithelial covering of these villi may not dis-

appear, but undergo certain changes and ultimately develop into cystic growths. These are interesting speculations, but for our present purpose we shall not pursue them further.

The degenerative process in these diseased villi generally begins in an early period of pregnancy; usually before the placenta has begun to form. In such cases the whole superficies of the chorion participates in the diseased condition. When the onset of the affection is delayed, the disease is then limited to that part of the chorion which takes part in the formation of the placenta. The epithelium remains unchanged, except in being increased in quantity. It is in the connective tissue stroma that the earliest manifestations of the affection appear first. The small spaces that are normally found here gradually become increased in size from an accumulation of fluid. This distention continues until the villi are so thinned out that nothing remains but their epithelial covering filled with fluid. By this time the chorion will have lost the greater part of its blood-vessels, but nutrition may be maintained to a certain extent by its connection with the decidua. Sometimes this attachment to the decidua is so firm that the mass is intimately adherent to the uterine wall. They have even been known to penetrate well into the wall of the uterus. The disease is essentially one of pregnancy, and there are no grounds for asserting that it may occur independently of conception, as has several times been maintained. There are two points in this connection that should steadfastly be borne in mind. The first is, that very often these diseased villi do not come away at once. Detached portions may be passed from time to time for an almost indefinite period. In the case of a woman becoming a widow while these vesicles are forming and coming away at intervals, it can readily be understood how unjust suspicion might reflect upon her chastity. Again, it should not be forgotten that genuine hydatids may affect the substance of the uterus and be expelled by the vagina. The heads and hooklets of the echinococci can be discovered by the microscope, while the hydatids of the chorion possess no such heads or hooks.

There are so many varieties in degree in the different stages of this disease that it is extremely difficult to make accurate classifications. This being so, it is not to be wondered at that the different appearance of the mass expelled has given rise to so much confusion. The vesicles may be so small as to be no larger than the head of a pin, or they may be as large as a cherry. The fluid may be small in amount and quite clear. In such instances it may be impossible to see the cyst wall. They burst their contents, which come dribbling away, and the thin wall may remain in the uterus for an indefinite time, or become dissolved. From clear fluid they may vary in all shades of color up to dark brown or red. When clear or of a pellucid consistency, these cysts are frequently called "vesicular moles." There may be en-

tangled up with the cyst a certain amount of the deciduous membrane and organized clot, which gives the mass a fleshy appearance. This is called a "carneous mole," but should not be confused with the carneous mole so frequently found associated with diseased conditions of the decidua.

The symptoms accompanying cystic chorion are not well defined or constant. In the beginning there are no symptoms of sufficient importance to call for medical aid. There may be vague and uncertain ailments that are unusual. As pregnancy progresses, it does not continue in a normal course. Reflex disturbances may be more prominent and vomiting quite persistent. When the vesicles increase in size there will be a proportionate enlargement of the uterus. This, however, should not be considered as diagnostic, for other conditions may cause the uterus to be larger in size than normal. The first sign of any practical importance will be the discharge of a watery or sanguineous fluid from the womb. This is frequently clear, but is often of the consistence and color of currant juice. Parts of the cysts can occasionally be found mixed with the discharge, and this is the only positive diagnostic proof of the disease. On making very careful examination of the uterus, there may be discovered an irregular bulging or a soft or boggy feeling. When cystic disease begins it is generally at the time when the young placenta is beginning to form and the villi of the chorion are getting ready to dip into its sinuses. Before this time, the villi over the whole surface of the decidua are of about equal growth, and all may be equally affected. There would then be a more luxuriant growth of vesicles. After the beginning of the placenta, the villi of that part of the chorion which is not concerned in the development of the placenta cease to mature further and gradually disappear, although by a microscopic examination their presence can be discriminated up to a late period of gestation. The importance of recognizing this peculiar action of the villi lies in the fact that, when the disease does not begin until after the third month, it is almost certain to be limited to the region of the placenta. Should it commence previously to this time, the villi, scattered over the whole surface, take on increased activity and the disease becomes general. A modified form of this condition occurs when localized areas of the chorion become so involved that there may not be sufficient disturbance to the nutrition to interfere with the vitality of the fœtus, and pregnancy advances to the full term of gestation uninterrupted. There are many instances on record where fœtuses have been born alive but the placenta have been in a state of partial degeneration due to the villi of the chorion being first involved. Rarer instances may be found recorded through medical literature where twin fœtuses have perished, and a third child living has been born with its particular placenta in a perfectly healthy condition. So far as the subject affects us here, the practical question is whether the cystic disease of the

chorion antedates the death of the embryo, or whether the degeneration follows as a result of the death of the embryo. The general consensus of authorities maintains that the degenerative process is the first to be established, and that this so vitiates the elements necessary for the nutrition of the fœtus as to bring about its death and expulsion. The remote cause of the disease is a difficult one to fathom. Many interesting opinions have from time to time been advanced upon this subject. Virchow, who has given this matter a great deal of attention, believes that the remote cause, or starting point, lies in the decidua. He asserts that the endometrium, previously to pregnancy, becomes inflamed and thickened to such an extent that the chorionic villi are incapable of becoming properly embedded in its substance. The villi in such a case cannot properly take root, and the fœtus does not receive sufficient nourishment for its normal growth and full development.

In parting from this subject we again emphasize the point that cystic chorion may be retained in the uterus for an indefinite length of time without giving rise to any important symptoms, and they then may give occasion for suspicion as to the chastity of these women. Dr. McClintock calls attention to this fact, and says that "Hydatids may be retained in the uterus for many months, or even years, or a portion only may be expelled, and the residue may throw out a fresh crop of vesicles to be discharged at a future occasion."

Great caution should be taken in curetting the uterus after it has retained these vesicles for a time. They have the faculty of penetrating into its muscular substance and of making it so soft and friable that a sharp curette is liable to penetrate through into the peritoneal cavity if the operation is improperly performed.

Morbid Conditions of the Amnion.—The amnion is the innermost of the true fœtal membranes. Its formation is intimately associated with that of the chorion and there is a close interdependence between them. When describing the anatomy of the chorion the method of development of the amnion was referred to. In its earliest days an embryo resembles in shape a canoe turned upside down, and consists of a longitudinal axis, a neural canal, and an alimentary canal. At either extremity a small crescentic depression takes place, caused by a puckering of the blastoderm. From these depressions the somatopleure, which is lined by epiblast, gradually arches up from the two extremities and sides of the embryo. By degrees these two folds approach each other and coalesce as they converge. In this manner the amnion is formed. At first it lies in close contact with the embryo, but, as development advances, it gradually becomes distended with fluid. This fluid in appearance is clear and contains traces of albumin, urea, and grape sugar. It increases in quantity during the first six months of pregnancy and then gradually diminishes. The source of the liquor amnii has long been a debatable question and conflicting views have been

held in regard to it. The older writers maintained that it was derived from the mother and was the result of exhalation. Recent authorities prefer the theory that it is an exudation from both the foetal and maternal blood-vessels. In the later months, when the bladder is fully formed, it is supposed that the urine of the foetus is evacuated into the amniotic cavity. This is probably correct, for cases have been recorded, by perfectly reliable authorities, in which the death of the foetus has occurred *in utero* from rupture of the bladder as a consequence of overdistention when there was an imperforate urethra. There are remarkable variations in the quantity that may be present. This is constantly demonstrated during normal labor. Occasionally the amount of fluid is so slight as to be scarcely noticed. This constitutes the "dry labor" of the laity. Its function is purely mechanical. It serves as a protection against concussions or injuries during gestation; during the early stages of labor, by gentle and uniform pressure it aids very materially in opening the mouth of the womb. Although so wonderfully protected, the amnion does not always escape from the effects of injuries. Sudden jumps, falls, blows, or knocks may be sufficient to cause its detachment or to rupture the delicate membrane and cause the expulsion of the foetus. It would seem that this may occur more readily at certain times than at others. In the early weeks of pregnancy we have already seen that extravasations are quite frequent in the decidua membrane; occasionally they are so sudden and violent as to crush through both the chorion and amnion into the amniotic cavity. The amnion is then torn from its moorings, and the result is the inevitable destruction of the foetus. The earlier in the stage of pregnancy such an extravasation takes place the more liable is the amnion to be affected. Its structures are then frail and delicate, and any unusual local disturbance is quite sufficient to cause its detachment or rupture. What may be sufficient to cause such a disaster in one instance may not in another. This is to be explained by the difference of texture and durability in different membranes, for they are not all of a uniform thickness. Sometimes we find the walls of the amnion so thin that the least pressure or uterine contraction will cause them to give way; on the other hand, they are sometimes found so tough and durable as to interfere with the progress of labor and they may readily resist violent interference. The question as to whether a true inflammation of the amnion can take place is variously estimated. The general consensus of opinion appears to be in the negative. It is true that after peritonitis, kicks, and blows, the blood-vessels of the amnion are found to be congested and tortuous, but it does not therefore necessarily follow that an inflammation has taken place.

The pathological condition that most frequently affects the amnion, and the one that is most familiar to us, is that of hydramnios. It is characterized by a superabundance of liquor amnii. Just what constitutes

a normal secretion of liquor amnii is difficult to determine in many instances. Generally speaking, it is considered an excess when the amount is over two quarts. The exact cause of hydramnios is not definitely understood. Some authorities attribute the condition to an excessive secretion on the part of the amnion, while others maintain that in all probability it is due to an inflammation of that membrane. Various other opinions have been promulgated as to its aetiology, but none of them are considered as adding much to our definite knowledge of this peculiar subject. There is a probability amounting almost to a certainty that it is of foetal origin. There does not appear to be found any deviation from health on the part of the mother in this disease. That it is of local origin is inferred from the fact that, when hydramnios is present in twin pregnancies, one ovum only is affected. An impediment to the foetal circulation through the heart or liver would seem to be the most probable cause. Congenital defects in the heart or syphilitic conditions of the liver would lead to a passive congestion that might give rise to mechanical obstruction sufficient to cause the excessive secretion of the liquor amnii. So far as the mother is concerned, its effects are mainly mechanical. It is usually toward the last months of pregnancy that the disease manifests itself. Gradually the abdomen begins to enlarge at a greater rate than in ordinary pregnancy and the mother begins to think that she is to have twins or triplets. The distress is frequently very troublesome. The enlarged uterus so distends the abdomen as to press the diaphragm upwards to such an extent as to interfere seriously with respiration.

The effect upon the child is generally serious. It is ill-developed, and, should it survive until the period of birth, it is too feeble to survive for long. Such children are often affected with dropsy, hydrocephalus, or other congenital defects, indicating that the condition is of foetal origin.

(To be continued.)

THE COMPARATIVE PATHOLOGY OF THE JEWS.

BY MAURICE FISHBERG, M. D.,
NEW YORK.

THE influence of race and nationality on the susceptibility, and comparative (because we know of no absolute) immunity to the various diseases that afflict mankind, is at present well recognized by the medical profession. The physicians of the United States have especially studied the comparative pathology of the negro race, owing to the fact that these people are to be found in relatively great numbers, particularly in the Southern States. The total number of Jews in the United States at present is estimated to be 1,058,135 (1); and it is quite surprising that, on consulting the most important

medical journals published in the United States, I have been unable to find any article on the comparative pathology of these people, excepting a few scattered notes and remarks. The literature on this subject in Europe is also very meagre, and many difficulties have been met with while collecting the materials for the following paper.

All over Europe, wherever tested, the Jews have been found, in spite of their frail physical aspect, to live longer than the Christians. Thus we find that in Budapest, Hungary, the average duration of life of the Christian population in the city is twenty-six years; that of the Jews, thirty-seven years. The Christians between the ages of one and fifty have a death rate of 14 per cent., the Jews one of only 10 per cent. Among the Christian population 50 per cent. of all new-born children will reach the age of thirty years; from the Jewish population, 50 per cent. will reach the age of fifty years. Eight per cent. of Jews reach the age of from eighty-five to ninety years, while only 2.4 per cent. of the Christians reach this age. Twelve per cent. of the Jewish population have reached the age of from sixty to seventy years, while only 9.8 per cent. of Christians have reached this age (2).

In Prussia, according to Mulhall (3), the death rate has been found to be yearly per 1,000 population:

TABLE I.

Years.	CHRISTIANS.		JEWS.	
	Males.	Females.	Males.	Females.
1822-40.....	28.7	27.0	22.1	19.1
1841-66.....	30.2	28.2	19.8	17.9

In Austria the number of births among the Jews has been calculated to exceed that of the deaths in 30.80 per cent., and among the rest of the population as only 28.30 per cent. (4).

In Amsterdam the mortality of children under five years of age has been found to be: among Christians, 11.52 per cent.; among the Jews, only 8.85 per cent. The death rate of adults, of the ages between twenty and fifty years, for Christians, 5.98 per cent.; for Jews, only 3.06 per cent. (5).

Table II shows the relation of births and deaths among Jews. In Algiers we find that in 1856 there were (6):

TABLE II.

	Europeans.	Mussulmans.	Jews.
Births.....	1,234	331	211
Deaths.....	1,553	514	187

The excess of births over deaths among the Jews is quite evident.

In Roumania, where the Jews are found to be in numbers almost equal to that of the Christians, we find that (7) during three years the births and deaths were as in Table III:

TABLE III.

Years.	BIRTHS.		DEATHS.	
	Jews.	Orthodox.	Jews.	Orthodox.
1884....	9,729	185,000	4,626	114,300
1885....	9,542	197,000	5,036	114,000
1886....	9,458	196,000	5,194	124,500

We see from these figures, that in 1884 the proportion of births among the Jews was 2.10 to one death; while the births among Christians were only 1.62 to one death. Almost a similar proportion can be reduced from the other figures given above.

We thus see that, almost all over Europe, the Jews enjoy an unprecedented tenacity of life, showing a lower death rate and an excess of the number of births over deaths. Another important fact is that, almost everywhere, the Jews, at present, show a proportionately smaller marriage rate, and produce relatively a less number of children to each marriage than Christians. This fact goes to prove that it is his longevity that gives the Jew his unprecedented tenacity of life over that of the Christians, and not the number of marriages and births. Thus, in Prussia, the Jewish population, from 1822 to 1840, increased 34.5 per cent., while, in the same lapse of time, the Christians augmented only 28 per cent., increase by immigration being about the same. There was one birth to every twenty-eight Jews, one to every twenty-five Christians; one marriage among every 139 Jews, one among 112 Christians; one death among forty Jews, one in thirty-four Christians (8).

At Furth, an average for twenty-five years gives one marriage to every 128 Christians, while Jews number 149 to one marriage. Among Christians it required but twenty-nine inhabitants to recruit one birth, while among Jews it required thirty-five (9).

For the United States we find that Billings states, in an analysis of the vital statistics of 10,618 Jewish families living in the United States, that there occurred during five years 6,038 births. "The total average birth rate for the whole population," as Dr. Billings remarks (10), "was 20.81 per 1,000, which is at least 10 per 1,000 lower than the average birth rate among the general population (of the United States). A fairer means of comparison, however, is the ratio of births with the reference to the number of women of child-bearing ages present, viz., those between fifteen and forty-nine years of age, inclusive." As Billings shows by statistics, "this rate was 72.87 per 1,000. The corresponding rate in 1880 in Massachusetts was 82.9, and in Rhode Island 86. The birth rate among the Jews," continues Dr. Billings, "is therefore decidedly lower than it is among the average population." There are similar statistics in many European countries where large numbers of Jews live. "To make up for this smaller number of births," says A. Leroy-Beaulieu (11), "they lose almost everywhere a perceptibly smaller number of children by deaths. They bring fewer children into the world, but they bring more of them to maturity. It would seem as if, with their characteristic cleverness at calculations, they had

instinctively solved the difficult problem of population in the manner most advantageous to themselves and most satisfactory to the economists."

Dr. Stallard, in his work on *London Pauperism*, states that the mortality among Jewish children from one to five years of age is only 10 per cent., while among the Christians it is 14 per cent. The average duration of life of the Christians in London is thirty-seven years; of the Jews, forty-nine years.

In the United States the Jews show a similar unprecedented tenacity of life. The reports on vital statistics from the eleventh census prove conclusively that the American Jews are not behind their European brethren in their resistance to death.

W. L. Ripley, considering this subject, says that the tenacity of life in the Jew "far exceeds, especially in the United States, that of any other known people. This we may illustrate by the following example: Suppose two groups of one hundred infants each, one Jewish, one of average American parentage (Massachusetts), to be born on the same day. In spite of all the disparity of social conditions in favor of the latter, the chances, determined by statistical means, are that one half of the Americans will die within forty-seven years; while the first half of the Jews will not succumb to disease or accident before the expiration of seventy-one years. The death rate is really but little over half that of the average American population. This holds good in infancy and in middle age" (12).

On consulting the *Report on Vital Statistics of the Eleventh Census*, prepared by Dr. John S. Billings, we find that the population in 1890, during the census year in New York city, contained 334,725 Americans, 55,572 English and Welsh, 399,348 Irish, 19,627 Scotch, 16,239 French, 403,784 Germans, 80,235 Russians and Poles (mostly Jews), 9,647 Canadians, 13,311 Scandinavians, 15,555 Hungarians, 12,287 Bohemians, 54,334 Italians, and 74,963 other foreigners or persons of unknown race. We see from these figures that New York is unsurpassed by any other city in the world to show us the death rates of the Jews as compared with other nations.

In Table IV, taken from the *Report of Vital Statistics of New York City*, the death rate per 1,000 of the population during six years ending May 31, 1890, is

clearly shown, with distinction of the birthplaces of mothers. The birthplace of the mother is the best means at our command for the indication of the probable race of a given individual.

TABLE IV.
MORTALITY PER 1,000 POPULATION.

Birthplace of mother.	All ages.	Under 15 years.	15 Years and over.
United States.....	32.43	54.01	15.91
England and Wales....	27.67	50.53	20.78
Ireland.....	32.51	50.87	28.01
France.....	23.28	47.01	17.86
Germany.....	24.27	46.97	17.04
Russia and Poland....	14.85	28.67	6.21
Hungary.....	22.43	47.21	8.45
Bohemia.....	43.57	82.57	20.31
Italy.....	35.29	76.41	12.27

From this table it is seen that the death rate of those whose mothers were born in Russia and Poland is lower than that of almost any other nationality. These Russians and Poles were nearly all Jews, living in poverty, and overcrowding in packed tenements of the lower East Side of the city. Moreover, their low death rate, as Dr. Billings states, does not fully appear in these figures, because a considerable number of those whose mothers were born in Hungary and Germany are also Jews with low death rates. If it were possible to separate them, the death rates of the Germans and Hungarians would stand at much higher figures.

Then, again, there were among those registered as Russians and Poles a certain number of non-Jews, especially of the Poles. If we could separate these non-Jewish Poles in a separate group, the mortality of the Jews would be much lower.

This can be done with a fair degree of accuracy by observing the death rates in the districts in New York city the population of which consists mostly of Russian and Polish Jews. The most important of these districts is the Tenth ward, which had, at the time of the eleventh census, a total population of 57,596, the great majority of whom consisted of Jews from Russia and Poland. It is also important to note that this was also the most densely populated ward in the city, the average number of persons to an acre being 543.36, with 38.50 persons to each dwelling. This ward is divided into two sanitary districts, "A" and "B." The comparative death rates of the various nationalities living in these districts can be seen from Table V:

TABLE V.
DEATH RATES PER 1,000 PERSONS WHOSE MOTHERS WERE BORN IN:

AREAS.	UNITED STATES (WHITE).		IRELAND.		GERMANY.		RUSSIA AND POLAND.		OTHER FOREIGN COUNTRIES.	
	Under 15 years...	15 Years and over	Under 15 years...	15 Years and over	Under 15 years...	15 Years and over	Under 15 years...	15 Years and over	Under 15 years...	15 Years and over
The City.....	54.01	15.91	50.87	28.01	46.97	17.04	28.67	6.21	40.68	13.00
District A.....	136.73	43.57	103.88	63.57	74.21	37.25	31.94	6.18	73.30	14.26
District B.....	77.52	23.37	98.71	51.22	60.36	23.36	26.36	4.39	30.20	6.86

From this table we see clearly that those whose mothers were born in Russia and Poland, and who were almost exclusively Jews, have the lowest death rate; and that, while the overcrowding in tenements and unsanitary conditions had a great influence in raising the death rates of the non-Jewish population of this ward in comparison with that of their average in the city, the Jewish death rate was almost unaffected. This is another proof of the comparative power of resistance to the noxious effects of diseases, and of the great tenacity of life of the Jews.

We arrive at the same conclusion when we study the report of the census in New York in the Seventh and Thirteenth wards, which is well depicted in Table VI, compiled by Hoffman (13), which is here appended.

Table showing the death rates per 1,000 population in the Seventh, Tenth, and Thirteenth wards of New York city, 1890, by birth place of mother:

TABLE VI.

Ages.	Total.	United States (includes col- ored).....	Ireland.....	Germany.....	Russia and Poland (mostly Jews).....
Total.....	26.25	45.18	36.04	22.14	16.71
Under 15 years...	41.28	62.25	40.71	30.38	32.31
15 to 25 years....	7.55	9.43	15.15	7.14	2.53
25 to 65 years....	21.64	25.92	39.51	21.20	7.99
65 years and over.	104.72	105.96	120.92	88.51	84.51

But while the unsanitary conditions, poverty, and want did not materially increase the death rates of the Jews living in New York, the death rate of the Jews in the country is decidedly lower than that of those in the city. Thus we find in an analysis of the vital statistics of 10,618 Jewish families, including 60,630 persons living in the various parts of the United States, who were, in the average, in a better economic condition, that they have a death rate of only 7.11 per 1,000 (14), as against 14.85 per 1,000 of the Russian and Polish Jews in New York, and 16.71 of those living in the Seventh, Tenth, and Thirteenth wards of New York.

On carefully considering the above facts and figures, we are forced to agree with W. L. Ripley, that the Jews show an "unprecedented tenacity of life." This is more forcibly depicted by Dr. John S. Billings in his *Report on the Vital Statistics of the Jews in the United States* (15) by a table of the expectation of life of the Jews in the United States, as compared with that for England and the average American population of Massachusetts. From that table we find that a young Jewish child of five years would have, on an average, about sixty-two years more to live; the average Americans of Massachusetts, only fifty-three years; a Jew at the age of twenty-five would have, on an average, forty-five more years to live; an American, only thirty-nine years, etc.

The experience of European observers about the low death rate of the Jews, as compared with that of non-

Jews, is thus fairly well sustained by the United States census. It is only surprising that very few physicians of those who practise among these people are aware of this fact.

Dr. Glatter (16), the director of the statistical bureau of Vienna, gives the following table (VII) illustrating the relative frequency of disease among different races in the same locality:

TABLE VII.

	Number ill.	Number to 1,000 Inhabitants.
Magyars.....	6,034	534
Germans.....	3,806	223
Slavonians.....	1,522	182
Servians.....	252	28
Jews.....	1,540	32

These figures show that the Jews are relatively less liable to be attacked by disease.

When we turn again to the causes of death among the Jews, we find that the most dangerous diseases, as tuberculosis, pneumonia, nephritis, typhoid, malaria, etc. (except diabetes), claim a proportionately smaller number of victims from among the Jews than from among non-Jews. The testimony of many European physicians proves, also, that most of the epidemic diseases kill, proportionately, a smaller number of Jews than of non-Jews. Thus the mortality of children from small-pox in Posen during twenty-six years was: Catholics, 3.13 per cent.; Protestants, 2.26 per cent.; Jews, only 0.9 per cent. (17).

This may be due to the fact that the Jews submit more readily to vaccination than non-Jews (as can be readily seen even in New York, where they flock to the health board for that purpose proportionately more frequently than Christians); but on consulting the reports of epidemics of other diseases we arrive to almost the same results. For instance, Tschudi, in speaking of the plague in 1346, says that this disease did not affect the Jews of any country. Fracastor mentions the fact that the Jews escaped completely the epidemic of typhus of 1505. Rau mentions the same immunity from typhus observed at Langeons in 1824. Ramazzini insisted on the immunity of Jews from the intermittent fevers observed in Rome in 1691. Degner says that the Jews escaped, in 1736, the epidemic of dysentery of Nimegue. Michael Levy remarks that this immunity was manifest at the same time in the French and in the Israelites (18).

During the epidemic of cholera in Budapest, in 1851, there was a mortality of 1.85 per cent. among the Christian population, while the Jews succumbed only to the extent of 0.257 per cent.—i. e., seven times less (19); a writer in the *Revue scientifique* (20) states that during the epidemic of cholera in London, in the 'seventies, the Jews remained almost not at all affected. Again, in Algiers, notwithstanding the fact that the Jews are crowded in small and dark dwellings, often in basements, they still are more resistant to the effects of contagious diseases than non-Jews, as can be seen from the follow-

ing figures (21). During the epidemic of cholera the mortality was found to be as in Table VIII:

TABLE VIII.
MORTALITY PER 1,000 POPULATION DURING THE
CHOLERA EPIDEMIC IN ALGIERS:

	1844.	1845.
Europeans.	42.9	45.5
Mussulmans.	32.4	40.8
Jews.	21.6	36.1

This peculiar resistance of the Jews to the noxious effects of contagious disease has been noted already in the middle ages, especially during the great epidemics in Europe of the plague known then as the "Black Death." At that time they suffered severely, because of the fact that they were affected by the pestilence to a less degree and had a proportionately smaller mortality than the Christians. The Jews were accused of being the special emissaries of Satan in causing the plague; it was said that their immunity was due to a special protection by Satan as a compensation for the services they rendered him by their wholesale poisoning of the wells; the use of poisoned water was thought the cause of the Christians being attacked by plague. By torturing and murdering the Jews, and especially by confiscating their property, it was thought that the Almighty might be propitiated, the terrible scourge driven from good Christian countries, and Satan thwarted. As a result of this, hundreds of thousands of Jews were burned or otherwise killed. The plague disappeared in due time—of course only after killing 25,000,000, a quarter of the population of Europe at that period.

Such immunity of the Jews to contagious diseases is not observed at the present time; during the late epidemic of cholera in 1892-1894, in Russia, it has been observed that the Jews were no more spared by the pestilence than their non-Jewish neighbors, and that in some cities the Jews were even more affected than the Christians. But the percentage of deaths from a given number of cases has, as a rule, been smaller among the Jews than among non-Jews. Thus, Dr. Barazhnikoff reported to the St. Petersburg Medical Society, in 1894, that, during the epidemic of cholera in the government Mogileff, the morbidity among the Jews was greater, and the disease, as a rule, ran a severer course, than among the Christians. But the percentage of mortality was smaller among the Jews. He adds that the fact must not be forgotten that the Jews in that locality are more intelligent than the Christians and take more care of their health, although they are generally poorer (22).

Turning now to the causes of death among the Jews in the United States, we find that the Jews show a smaller mortality than the Christians from the most formidable diseases, as tuberculosis, pneumonia, malaria, typhoid, etc. Thus, in the *Report on Vital Statistics of the Eleventh Census*, we find that in New York city the death rates from consumption during the six years ending May 31, 1890, were, for each 100,000 of population of each of the following nationalities:

Colored, 744.4; mothers born in Ireland, 645.73; in Bohemia, 499.13; Scotland, 384.12; Scandinavia, 357.00; Canada, 352.32; Germany, 328.80; France, 324.98; England and Wales, 322.50; Italy, 233.85; United States (white), 205.14; Hungary (mostly Jews), 155.05; Russia and Poland (almost all Jews), 98.21. These figures show us that the Jews in New York die from consumption about seven times less than the negroes, six times less than the Irish, five times less than the Bohemians, etc. In the analysis of the vital statistics of 10,000 Jewish families by Dr. J. S. Billings, referred to above, we find that the death rate from consumption in 1,000 total deaths among these Jews was, for males 36.57, for females 34.02, while that of the United States (1880) was 108.79 for males and 146.12 for females, and of Massachusetts (1888), for males 129.22, and 146.97 for females (23). These figures, again, show that the general population of the United States suffers more than three times as much from consumption as the Jews, and that the population of Massachusetts suffers nearly four times more than the Jews. The best proof as to the low death rate from tuberculosis among Jews, however, can be found, on taking the vital statistics for the six years ending May 31, 1890, in the most densely populated spot of New York—that is, the Seventh, Tenth, and Thirteenth wards, the tenement-houses of which are inhabited mostly by Jews, under the most unsanitary conditions, in poverty and want. We find that, in these districts, the percentage of consumption was lower among the Russian and Polish Jews than among most of the other nationalities except the native-born population.

During the six years ending May 31, 1890, the death rate among the following nationalities living in these wards was found to be as in Table IX:

TABLE IX.

Mothers born in	Deaths due to all causes.	Deaths due to consumption.
Ireland.	6,224	1,210
Germany.	5,691	804
England and Wales.	437	57
Russia and Poland.	4,687	270
United States.	4,826	267

From these figures we see that the mortality due to consumption reached among the Irish 19.44 per cent. of the death rate due to all causes; among the Germans, 14.12 per cent.; among the English, 13.04 per cent.; among the Russian and Polish Jews, 5.76 per cent.; among those whose mothers were born in the United States (a great number of these in those districts were Jews), 5.53 per cent.

We thus find that the Jews succumb comparatively less than Christians to the white plague—consumption. This fact has also been repeatedly observed in various European countries. In London, according to the testimony of Dr. Behrend (24), consumption is less frequent among the Jews in the most squalid dens of Whitechapel than among the Christians. The latest communication

on this subject can be found in the *Revue d'hygiène et de police sanitaire*, by Tostivint and Remlinger, that only 34 of the entire number of 2,744 deaths among the Jews of Tunis in the five years from 1895 to 1899 were due to tuberculosis—*i. e.*, 1.24 per cent. It is further estimated that the average annual mortality from tuberculosis among the Mussulman Arabs, between the years 1894 and 1900, was 11.30 per 1,000; among the Europeans, 5.13 per 1,000, and among Jews, only 0.75 per 1,000 (25).

The various other acute infectious diseases, diseases of the respiratory and urinary systems, of the liver, and nervous system, according to the *Report on Vital Statistics of the Eleventh Census of the United States*, claim a proportionately smaller number of deaths from among the Jews than from among the non-Jews. And, according to Dr. John S. Billings's *Report on Vital Statistics of the Jews in the United States*, we find that "the Jews have suffered a relatively greater loss than their neighbors, by deaths from diphtheria, diarrhoeal diseases, diseases of the nervous system (and especially diseases of the spinal cord), of the circulatory system, bones and joints, and of the skin, while their mortality has been relatively less from the tubercular diseases, including consumption, scrofula, tabes, and hydrocephalus, than the other people with whom they are compared."

Alcoholism and syphilis are diseases that are very rare among Jews. During the six years ending May 31, 1890, alcoholism caused in each 100,000 persons, of each race in New York, 31 deaths annually among the Irish, 10 among the Germans, 9 among the Americans, 6 among the negroes, 3 among the Italians, and only 1 among the Russian and Polish (Jews). This may give us a clue to the reason why the Jews suffered such a small loss through nephritis, as the following figures show: During the same six years nephritis caused in each 100,000 persons of each race in New York, 142 deaths among the Irish, 67 among the Germans, 54 among the Americans, 27 among the Italians, and 18 among the Russian and Polish (Jews).

That syphilis is relatively infrequent among the Jews has been observed almost all over Europe. Thus, according to Mr. Jonathan Hutchinson, syphilis is less common among Jews than among Christians; at the Metropolitan Free Hospital, in the Jews' quarter of London, in 1854, the proportion of Jews to Christians among the outpatients was nearly one to three, yet the ratio of cases of syphilis in the former to those in the latter was only one to fifteen, and that this difference was not due to their superior chastity was evident from the fact that the Jews furnished nearly one half of the cases of gonorrhœa that were treated during the same period (26).

Dr. A. Cohen, late senior house surgeon of the Metropolitan Free Hospital in London, has, at the request of Mr. Joseph Jacobs, collected the statistics of venereal diseases that came to this hospital during his service in 1882-1883, and has found that the proportion of Christ-

ian to Jewish patients affected with syphilis has been as three to one (27).

We have not exact statistics as to the frequency of syphilis among the Jews in the United States, but the testimony of physicians practising among this people goes to show that, while among the Jews syphilis is often met with, it is not so frequently encountered as among non-Jews.

The fact that the Jews are not very often attacked by alcoholism and syphilis has a very important bearing upon the comparative pathology of their people. Besides the fact that this is one of the reasons that nephritis and diseases of the liver (especially cirrhosis) are less commonly met with, the varieties of nervous diseases to which the Jews are most liable are also determined by these factors, as we shall see later in this paper.

A disease from which the Jews suffer more than any other nationality is diabetes. It is extremely frequent among the Jews in large cities, according to Bordier (28); out of 400 patients suffering from diabetes, Freichs found that 100 were Jews—*i. e.*, twenty-five per cent. Osler (29), Strumpell (30), Naunyn (31), Saundby (32), and most other observers, say that the Jews are especially prone to this disease.

Dr. Heinrich Stern (33), in an exhaustive analysis of the mortality from diabetes in the city of New York in 1899, states that "the Hebrews, no doubt, are more commonly affected with chronic glycosuria than natives among whom they dwell. Out of the total of 202 deaths (from diabetes in New York city in 1899), fifty-four—that is, twenty-five per cent.—occurred in Jews. Of these, twenty-one were males, and thirty-three females." Dr. Stern further intimates that while "mental exertion, the characteristic modes of living, gluttony, alcoholic intoxication, etc., might be considered predisposing factors in the production of the diabetic state," it is his opinion that "the cardinal predisposing cause is the breeding in and in to which, in a very pronounced measure, the Jewish, as well as the Irish, race still adheres."

Dr. R. Saundby, again, states that the frequency of diabetes among the Jews is to be ascribed to the following cause: "The Jew raises himself easily, by his superior mental ability, to a comfortable social position, and notoriously avoids all kinds of bodily exercises" (34). This cause cannot hold good for the mortality from diabetes of the Jews in New York. As Dr. H. Stern has shown, twenty-five per cent. of the deaths from diabetes in New York are found to be in Jews; and, examining the original death certificates in New York city for 1899, "almost seventy per cent. of deaths occurred in tenement-houses, fifteen per cent. occurred in hospital practice and coroner's cases, and only fifteen per cent. in private houses. This tends to show that the malady has virtually little to do with high living" (35). Furthermore, the New York Jews living in tenements are hard working people—working long hours in sweatshops, having a sufficient amount of bodily exercise, so that the cause

that Saundby assigns for the prevalence of diabetes is not operative among them.

C. Van Noorden, in a recent paper on diabetes (36), states that it is his belief that the cause of the frequency of diabetes among Jews is the close intermarriage among them. Consanguineous marriages are really more frequent among Jews than among Christians (37), and this fact has been very much exploited by medical writers, who have attributed to it all the ills the Jews are liable to. We shall return to this question later in this article.

As to the other diseases to which the Jews are more or less predisposed, the various nervous and mental diseases stand out preeminently; after these come the diseases of metabolism, called by French authors arthritism and herpetism—for instance, gout, gall-stones and nephrolithiasis, chronic rheumatism, some forms of neuralgia and migraine, asthma, pulmonary emphysema, varicose veins, and especially hæmorrhoids, arteriosclerosis, and some diseases of the skin. Finally, some authors state that blindness, color blindness, myopia, trachoma, glaucoma, and almost all the skin diseases, are more frequent among the Jews than among the non-Jews.

Concerning the frequency of nervous and mental diseases among the Jews, the evidence is overwhelmingly abundant. It appears that the ancient Hebrews were already great sufferers of hysteria and insanity, as can be seen by many statements in the Bible, particularly in the New Testament, where it is mentioned that numbers of people "possessed with devils," lunatics, "men with unclean spirits," etc., called upon Christ for relief and that He cured them (see particularly St. Matthew, viii, 16; ix, 32; xii, 22; xvii, 15; St. Mark, v, 2; St. Luke, viii, 27; xiii, 11, and in many other places).

In modern times Charcot, Lancereaux, Oppenheim, Erb, Strumpel, Jolly, Möbius, Krafft-Ebing, Löwenfeld, Müller, Binswanger, Putnam, Collins, and many others, have observed this fact and speak of it in their textbooks and monographs. Neurasthenia and hysteria are mostly found among the Jews. Some authors have even stated that the majority of the Jews are neurasthenics and that most of the women are hysterical. Thus Raymond (38) states that hysteria is frequent among both men and women in Warsaw (Poland). The Jewish population of that city alone is almost exclusively the inexhaustible source for the supply of hysterical males for the whole continent. "Among the European nations," says Dr. Binswanger (39), "the Jews supply, relatively, the largest contingent of neurasthenics"; according to Dr. Jolly (40), "the Jews have a hysterical and especially nervous disposition to an overwhelming degree." "Nervous diseases, especially neurasthenia," says Krafft-Ebing (41), "affect the Jews with exceptional severity."

Dr. James J. Putnam (42) states that "the psychoneuroses in general are particularly common in the Latin and Hebrew races." Dr. Joseph Collins and Dr. C. Philips (43), analyzing 333 cases of neurasthenia which

came under their observation, have found that more than forty per cent. of the patients were of the Jewish race, although "their *clientèle* was not conspicuously foreign."

(To be concluded.)

THE CAUSES AND THE SIGNIFICANCE OF THE OBSTETRIC HÆMORRHAGES.*

BY J. CLIFTON EDGAR, M. D.,

NEW YORK.

OBSTETRIC metrorrhagia can, I believe, be most conveniently discussed by dividing the subject into three divisions, namely:

I. *The metrorrhagia of pregnancy or ante-partum hæmorrhages.*

II. *The metrorrhagia of labor or intra-partum hæmorrhages; and,*

III. *Puerperal metrorrhagia proper or secondary post-partum hæmorrhages.*

I. THE METRORRHAGIA OF PREGNANCY; ANTE-PARTUM HÆMORRHAGES.—Uterine hæmorrhage, moderate or severe, occurring during the forty weeks of pregnancy naturally suggests to our minds the six queries:

1. Is it a simple abortion or miscarriage?
2. Is it a case of placenta prævia?
3. Is it a premature separation of a normally situated placenta (accidental hæmorrhage)?
4. Is it one of ectopic gestation?
5. Is it a traumatic or spontaneous rupture of the uterus?
6. Is it menstruation occurring during gestation?

These are the principal ætiological factors in ante-partum hæmorrhage; still, it should always be remembered that the diagnosis must be confirmed by a careful consideration of the symptoms and signs present, since we observe, although less frequently, ante-partum hæmorrhage due to (a) the fever and local hyperæmia of the (1) exanthemata—as variola, scarlatina, and measles; (b) conditions of the heart, liver, and abdominal viscera producing obstructed venous return; (c) hæmatosalpinx; (d) sarcoma, fibroma, and polypus of the uterine body; and (e) to polypus and epithelioma of the cervix.

Less frequently still, ante-partum hæmorrhage, local in character, but non-uterine in origin, has been mistaken for one of the six main causes just stated. These hæmorrhages, usually slight in amount, come from (a) the urethra, due to causes in the urinary tract; (b) rupture of vaginal or vulvar varicose veins; (c) cancer of the vagina or vulva; and (d) anomalies of the intestines or anus, a common one being hæmorrhoids.

Most frequent and most important of the ante-

*Read before the Medical Association of the Greater City of New York, February 12, 1901.

partum hæmorrhages is the bleeding indicative of a threatened or inevitable abortion, which is due to a partial separation of the fetal structures before the complete formation of the placenta. All the manifold and varied causes of abortion and miscarriage have to do with this variety of hæmorrhage.

The possibility of menstruation continuing into pregnancy must also be granted. While it is true that menstruation is nearly always suspended during the whole period of gestation, returning from six to eight weeks after the birth of the child, still, exceptions to the condition of suspended menstruation in pregnancy occur now and then during the early months, and are explained by the fact that the uterine cavity is not obliterated by the fusion of the decidua reflexa and decidua vera until the close of the fourth month.

If the menses continue throughout pregnancy—a very rare condition indeed—there is probably an abnormal and incomplete fusion of the deciduæ. Some cases have been reported of women who menstruated only during pregnancy. Such reports should be carefully criticised, as such cases probably depend, without exception, on pathological conditions of the cervical canal.

From an examination of a large number of membranes and placenta, the result of interruptions of pregnancy in the third, fourth, fifth, and sixth months, I am convinced that hæmorrhage due to a low situation of the placenta is much more common than is usually supposed.

I mean, by this, that a large portion of the supposedly simple abortions and miscarriages are really instances of the implantation of the placenta in the lower uterine segment, with resulting hæmorrhage and evacuation of the uterus as a consequence of partial separation of the abnormally situated placenta, due to changes in the shape of the lower uterine segment dependent upon the growth of the uterus.

It is generally thought, and usually taught, that hæmorrhage from a placenta prævia does not show itself until the twenty-eighth or thirty-second week of gestation. I have in my collection a uterus with the fœtus and membranes intact, and a central placenta prævia, from a woman who died within a few hours from the first hæmorrhage, which occurred at the sixteenth week of pregnancy. A careful autopsy showed that death was due to acute anæmia produced by the hæmorrhage from the partial separation of the central placenta prævia.

Further, I am convinced that a careful study of the site of rupture of the membranes in instances of supposedly accidental hæmorrhage, will prove that hæmorrhage during pregnancy, and also during parturition, from the premature separation of a normally situated placenta, is a very, very rare condition indeed.

I have found that several cases of presumedly accidental hæmorrhage were really those of lateral placenta prævia; a more complete examination after fuller dilatation, and the examination of the rupture in the mem-

branes *post partum*, indicating the condition that caused the hæmorrhage.

Severe hæmorrhage from the partial separation of a normally situated placenta I believe to be a very rare condition; severe hæmorrhage from a low implantation of the placenta I believe to be much more common than is generally thought.

II. THE METRORRHAGIA OF LABOR; PARTUM OR INTRA-PARTUM HÆMORRHAGE.—For convenience sake, I am accustomed to describe intra-partum hæmorrhages as those of—

1. The first and second stages; and,
2. Of the third stage.

1. *Intra-partum Hæmorrhage of the First and Second Stages.*—This is due principally to (a) *premature separation of a normally or abnormally situated placenta*; (b) *ruptures of the uterus or cervix*; and (c) *fibroid tumors, malignant disease of the genital tract, or rupture of varicose veins.*

2. *Intra-partum Hæmorrhage of the Third Stage.*—Here, first and foremost, stands, (a) *uterine inertia* as the most important ætiological factor; uterine inertia occurring with a partial or complete separation of the placenta. Next in importance comes (b) *lacerations of the genital tract*, namely, of the lower uterine segment, the cervix, vagina, and perinæum. Another important cause, not often taken into account, is (c) *insufficient contraction of the lower uterine segment in cases of low implantation of the placenta.* Here, while the fundus contracts firmly and completely, an imperfectly contracted lower segment permits of fatal hæmorrhage from the open blood-vessels of the low-situated placental site. (d) *Partial or complete inversion*, although a most infrequent cause, must be enumerated; and the likelihood of *fibroids* of the uterus or *cancer* of the genital tract must be borne in mind.

III. PUERPERAL METRORRHAGIA PROPER, OR THE POST-PARTUM HÆMORRHAGES.—Puerperal hæmorrhages are those occurring between six hours after the completion of the third stage of labor and the completion of the normal period of involution, namely, six weeks.

These hæmorrhages depend almost wholly upon the proper management of the second and third stages of labor and on the care the woman receives during the first few hours or days of the lying-in state.

The amount of the lochial discharge varies in different women. In some it always continues longer and is more abundant than in others, yet not long or abundant enough to justify us in calling the case one of secondary post-partum hæmorrhage.

As in intra-partum hæmorrhages, so in post-partum, the hæmorrhage may come on in so sudden, so unexpected a manner that there will be no premonitory symptoms of the accident, the external flow of blood being the first symptom.

The causes are *general* and *local*.

1. *Among the general causes are:*

(a) Mental emotions, as shock, anger, fright, fear; (b) disturbances of the general circulation, as from abuse of stimulants, the excessive use of chloroform, and certain conditions of the heart and liver which interfere with the return circulation; (c) certain blood conditions, as extreme malarial poisoning, albuminuria, and puerperal sepsis; (d) the acute infectious diseases.

2. Among the local causes are:

1. Anything which interferes with the proper contraction of the uterus during the puerperium, as (a) retained blood-clots, portions of placenta, or membranes; (b) a secondary placenta; (c) a distended bladder or rectum; (d) retroflexion; (e) inversion; (f) fibroid and polypoid tumors; (g) cervical lacerations; (h) malignant disease of the uterus; (i) simple subinvolution.

2. Causes inducing pelvic hyperæmia, as (a) assuming the upright position too soon after delivery; (b) too early sexual intercourse.

3. Thrombi which close the uterine sinuses may be dislodged by sudden exertion, or by septic processes in uterine phlebitis.

Uterine inertia or relaxation as a cause of hæmorrhage after the third day of the puerperium is of rare occurrence; retained blood-clots are more frequent in multiparæ, and may usually be prevented by careful attention to the uterus during the hour following the completion of the third stage, known as "the physician's hour." Hæmorrhage from retained placental fragments and membranes is due to an incomplete third stage, and may be prevented by careful examination of placenta and membranes at the time of expulsion and by removal of retained fragments.

The retention of small pieces of membrane, it must be remembered, does not necessarily induce puerperal hæmorrhage or other complication.

TROPICAL DYSENTERIES.*

BY STEPHEN M. LONG, M. D.,

ASSISTANT SURGEON, U. S. ARMY.

STRANGE as it may seem, you will find that many of our profession regard the ground of dysentery as pretty well covered, and the literature as quite exhaustive! To my mind it is just the reverse. Dysentery is a disease that ought to take the first place in our researches and be well studied, since it is unclassified and covers, under a vague name, four or five, or more, different types. Some may complain of the difficulties of its study, as it is mostly confined to tropical and semitropical countries; that, however, is no excuse for not going to the seat of the scourge and fighting it there, the more so in that, being a disease of war and famine, it has been for centuries the greatest and deadliest enemy that any nation or people can encounter. It is rumored that England is

going to have bullet-proof armor for her troops. If she only could enable the medical profession to devise a medicine that should make men dysentery-proof she would be seventy per cent. better off than with any bullet-proof armor she can devise.

Look at the war statistics and see the records of death from bullets or wounds, and those from dysentery. Yet, what has medical science found to check such a terrific disease? Very little. To-night I shall present to you the different forms of the disease as we actually see them in the Philippine Islands, with a brief description of their ætiology, symptoms, pathology, sequelæ, prophylaxis, and treatment.

The *first type* that I will consider is fulminating catarrhal dysentery. This is the most fatal of all dysenteries that I have seen. Nothing can be done to save the patients, and they generally die in from four to seven or eleven days. Its causation, up to the present time, has been ascribed to Shega's bacillus. The attack is very sudden, with a high temperature, rapid pulse, flushed face, tongue heavily coated, great prostration, and rapid emaciation; about fifty or more bowel movements a day, first watery, gradually becoming bloody and slimy. There is great tenderness all over the abdomen, with tenesmus in the rectal region. There is sometimes vomiting, which is very persistent. The symptoms of the disease are acute from start to finish. At the autopsy table we find the stomach generally inflamed, or predigested. The ileum and jejunum often do not present anything abnormal, except that the lower end of the ileum is sometimes inflamed. The mesenteric glands are always enlarged and hæmorrhagic. The disease is really confined to the large intestines, so that the whole tract from the ileocæcal valve to the anus seems to be one homogeneous necrotic mass. The lumen of the bowel is very much narrowed, but the calibre is enlarged three or four times, and measures from twelve to fifteen inches in circumference. The outer surface of the gut looks almost normal, but its inside is purple-red in color and inflamed through and through. The solitary glands are abolished, and no ulcers can be seen macroscopically. The whole thing represents a necrotic process in its acute stage.

As to its treatment, everything has been tried to save the patients, but without avail.

The *second type* that we often meet is simple acute dysentery. It is a disease that starts as a diarrhœa, and is often associated in the same subject with malarial fever. In the beginning, these cases are very easy to cure; yet they are the ones that hang over the patients for a long time and become chronic. There is no rise of temperature to speak of. The tenderness is very slight over the abdomen. There is some tenesmus, and the stools become bloody two or three days after the attack.

The *third type*, generally called the amœbic type, can be divided into four different classes: (a) the amœbic, (b) the trichomonadic, (c) the cercomonadic, and (d)

*Read before the medical officers, U. S. A. General Hospital, Presidio, Cal., May 4, 1900.

the mixed. As all of you know, the amœbic dysentery is the one most prevalent in tropical and semitropical countries. It gives no warning, and, when once established, it is a very hard task to dislodge it. While not very fatal in the start, in the long run, my impression is that it is the worst type, "the fulminating type excepted," of all the dysenteries, becoming the mixed type in its chronic stage. It is specially prone to cause liver abscesses. It has a tendency to become chronic and to kill the patients, either by its numerous ulcers perforating or producing excess of toxine in the system, by metastatic abscesses in other organs, especially the lungs, by paralysis of the intestines, or from inanition.

In the trichomonadic class, we find the infusorium *trichomonas intestinalis*, generally predominating in the stools. It is very obstinate to treatment and often becomes chronic.

In the cercomonadic class we find the *Cercomonas intestinalis* in the stools. When associated with the streptococcus, it is found to be very deadly.

The mixed class, so called, is the one that presents in the stools, besides the amœba, the *Bacillus pyocyaneus*, the staphylococcus, both aureus and albus, and the streptococcus. This type, as I have said, is very fatal on account of its complications.

All these classes are generally chronic and fatal in the long run, and the medical literature on these different types is practically *nil*. From the foregoing classes we get the following types:

The *Fourth Type*.—The chronic dysentery, so called, though mostly a sequela of the acute and amœbic forms, should nevertheless be regarded as a class by itself and treated accordingly.

The *Fifth Type*.—The gangrenous and diphtheritic are met with occasionally. They are generally fatal, either from perforation, from general peritonitis following, or from toxæmia. In these cases we find the patients passing big shreds of membranes. I had one patient that passed a tube cast of the internal lining membrane of the colon about fourteen inches long, and the specimen is preserved in the pathological laboratory of the First Reserve Hospital, Manila. The patient lived three or four days after its passage, and finally died from general peritonitis due to perforation of some ulcers at the ilcocæcal valve. In such cases there is a very weak and rapid pulse, the expression is very anxious, and the temperature rises in the evening up to 104° F.; there is also persistent vomiting, with an agonizing pain and tenderness over the abdominal region. The bowels move very frequently, passing blood and mucus in small amounts.

The sequela of dysentery met with in the Philippine Islands are many.

1. Its chronicity; 2, chronic gastritis and indigestion; 3, obstinate constipation; 4, paralysis (partial) of the large intestines, due either to obliteration of the glands and lack of secretion or to lack of innervation

and blood supply; 5, anæmia, from lack of assimilation of food; 6, the association with it of malarial fever; 7, typhoid fever; 8, neuritis; 9, atrophic cirrhosis of the liver; 10, chronic parenchymatous nephritis; 11, abscess of the liver; 12, metastatic abscesses of other organs, as of the lungs and kidneys; 13, inanition; 14, toxæmia; 15, dilatation of the stomach and intestines.

Somehow most of our liver abscess patients in Manila died, whether operated upon or not. The majority of cases represented multiple abscesses.

From the foregoing we must not infer, however, that in every case of abscess of the liver the patient dies. While I was at Cairo, Egypt, I saw many cases recovering after operation.

Prophylaxis.—I have very little doubt that dysentery is an infectious disease, being carried by the food or drink through the mouth. There is no word to express how much cleanliness is necessary to keep away from this scourge. If you ask me what is the best thing to do to avoid this disease, I should say, Don't touch anything which has not seen the baptism of fire.

Before I forget, let me mention that alcoholic drinks should not be regarded as prophylactic against the disease, but the reverse. In the Philippine Islands our hospitals have been using a great deal of brandy and whiskey, but I think the patients would be better off with blackberry brandy, sherry, or claret, in the chronic stages of the disease, if used cautiously. In warm climates, one thing we ought to remember is to take a purgative once every fortnight, if the bowels are sluggish and constipated. Exposure to the sun ought to be avoided between 10 A. M. and 5 P. M., if possible; also exposure to the night air. Shower baths or any other baths are always beneficial.

Treatment.—The treatment of dysentery is one of the most difficult problems to deal with, as it requires not only great knowledge of the therapeutical and physiological action of many drugs, but also a practical acquaintance with them and with the technique of administering them *per os* or *per rectum*. It requires, also, the knowledge of the different types of the disease. Here comes in the necessity of knowing how to use the microscope and of an acquaintance with the different methods of discovering the bacteria causing the disease. In time of war, and away from civilized countries, our task is often augmented by the physician being thrown on his own resources to deal with all these cases. The question, then, is how to simplify the matter and make our treatment the most valuable possible, using few drugs in a short space of time and under adverse circumstances. It is all right to experiment with new drugs in large city hospitals, but in time of war, or in epidemics, we must cure our patients with routine treatment and as quickly as possible. So I am going to mention to you only four drugs that can be obtained in any part of the world, and can be carried with the least possible inconvenience, besides having the sanction of the profession in general.

Eighty per cent., if not more, of the dysentery patients will be cured with one or more of these drugs, while the disease is yet in its infancy. So, when we get a case of dysentery or diarrhoea a day or two old, the first and right thing is to put the patient at once into bed, giving him an ounce of sulphate of magnesium in half a glass of warm water before breakfast, repeating it the same day if necessary. You will be surprised to see how many men will get well soon and report for duty. Calomel, one sixth, one quarter, or one half of a grain, given every hour, until four or six doses have been taken, and followed four hours later with half an ounce of salts, may answer the same purpose, but if there is any doubt as to the cure of the case, we can put the patient on another treatment. You have heard of the miracles as well as the failures of this great drug—*ipecacuanha*. This drug will often succeed if administered in the following manner: Put the patient to bed, and, while his stomach is empty, administer from fifteen to twenty drops of tincture of opium; then, fifteen minutes later, put an ice-bag on his head, apply a mustard plaster on his stomach, and give a hypodermic injection of morphine, one quarter of a grain (to give him a chance to sleep), and administer not less than forty grains of *ipecacuanha* by the mouth; at the same time give instructions to the patient or to the nurse that he is to remain quiet on his back for four hours without moving or taking anything by the mouth, and that, should the saliva increase in the mouth, it is not to be swallowed, but to be spit out. Out of ten patients, you will find that eight will retain it, and out of the eight who have retained the medicine, only one or two will need a second dose. So, from sixty to seventy per cent. will be cured by one administration, from ten to twenty per cent. will be cured by a second dose, and twenty per cent. will require some other kind of treatment.

This brings us to another class of medicine—I mean bismuth subnitrate. When I say bismuth subnitrate, I mean that preparation of bismuth only. The other preparations of bismuth have their own place in medicine, but it is not here. The bismuth subnitrate should be given in very large doses, if we expect good results. Forty or sixty grains every three or four hours is a very moderate dose, and if bismuth alone is not enough to check the trouble, then comes the mixed treatment, when the fourth drug steps in—that is, the great pain-killer, the comfort as well as the pacifier of so many sufferers—opium. This medicine should never be omitted from the list in treating diarrhoeas or dysenteries, whether acute or chronic. There are several ways of administering it, as with camphor, *ipecacuanha*, as in Dover's powder, or with Squibb's mixture, etc. My way has been to give forty grains of bismuth subnitrate and five grains of Dover's powder, well mixed, every three or four hours, as the case may indicate. I have forgotten to mention another and easy way of administering *ipecacuanha*—that is, in one-grain or half-grain doses every hour, for

two or three days; this often gives good results. I prefer, though, the first method. It is of no use going astray and trying other medicines, such as benzonaphthol, betanaphthol, salicylate of bismuth, bismuth subgallate, etc. All these medicines are good antiseptics, but most of them break up in the animal economy into different compounds and lose their antiseptic value. They have received a good trial, and have been proved inferior to our everyday medicines, bismuth, Dover's powder, and *ipecacuanha*. Sometimes, if the stomach gets out of order, bicarbonate of sodium in ten-grain doses, combined with bismuth and Dover's powder, acts like magic.

Allow me now to open another chapter of treatment which has not yet gained either the confidence or the sanction of the profession at large. There is a great struggle between the two schools, one advocating the internal administration, the other the topical application, of the drugs, either by injections, suppositories, or enemata. I have given the use of enemata a fair trial, and in some cases it is a life-saving treatment which should not be neglected. You will now and then come across cases in which all internal medicines will prove a failure, but which enemata will cure. Here, again, there is some diversity of opinion as to cold or hot water enemata. Well, in a few cases the cold water may be the best; but, in my estimation, the hot should be preferred for the following reasons: First, it is a better solvent than cold water; secondly, it is cleansing, clearing the bowels from slime and mucus; thirdly, it is aseptic; fourthly, it is absorbed by the tissues quickly; and, fifthly, it is well borne by many. Now, as to what medicines can be used with the enemata: I prefer, of all the antiseptics and germicides, silver nitrate, twenty grains to the pint, or quinine for amœbic cases. But let me mention one point in this connection: Do not forget to clean the bowels of the patient with a soapsuds enema before administering the medicated enema. The knee-chest or dorsal position can be tried. As to instruments for giving the enema, never use a hard-rubber catheter or the bulb syringe, as, when the ulcers are in the rectal region, alarming results may follow. A rubber bag or fountain syringe with a soft rectal rubber tube attached to it is all that is necessary for the operation. In this connection, let me mention two more drugs that have of late come into extensive use. One is the tincture of the chloride of iron, one drachm to the pint of hot water, mostly used by the English profession in India; and the second, peroxide of hydrogen. In this country, the tincture of iron, if tried, will be found to give as good results as nitrate of silver, but peroxide has few advocates yet. Normal salt solution enemata, laudanum, and starch-water enemata are also good and beneficial.

As to the question of treating chronic dysenteries of long standing in patients coming to us from the Philippine Islands, half starved and half dead, it is a very hard matter to deal with. But I should judge that a very highly nutritious and easily digestible food, administered

in small amounts at short intervals, or by rectal alimentation, thus giving rest to the stomach and intestines, might be tried, with as little drugging as possible. Milk should never be given as such, but always diluted with rice water, barley water, mineral, or lime water. Kumyss and allied preparations ought to be tried as articles of diet in such cases; fresh meat juice, also, in the shape of beef-tea, is invaluable. Now and then, saline enemata should not be forgotten, as they give tone to the bowels and afford the patient a chance to have them cleaned from the *débris*. Massaging of the abdominal region and the application of turpentine stupes or hot fomentations should not be forgotten.

ALCATRAZ ISLAND, CAL.

A DRESSING FOR COLLES'S FRACTURE.

By CHARLES L. DE MERITT, M. D.,

WEST HOBOKEN, N. J.,

ATTENDING PHYSICIAN TO CHRIST HOSPITAL (JERSEY CITY) DISPENSARY.

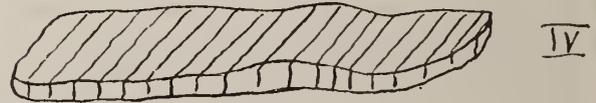

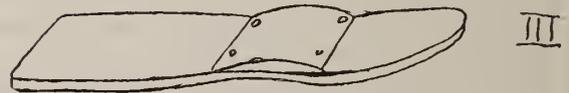

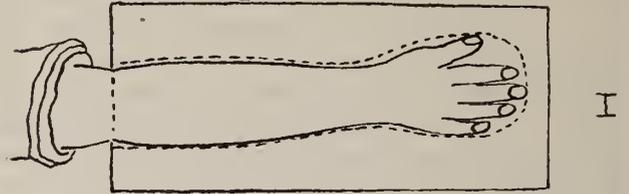

THIS splint is made from a thin piece of board, of one quarter or three eighths inch stuff, such as can be got by breaking up a soap box. Lay the pronated extremity on the board and outline it with a pencil, as shown in Fig. 1, from the finger tips to the elbow. Whittle out this pattern, which gives a board shaped as in Fig. 2. This should be done carefully to get the exact outline of the part. If measurement from the injured arm is too painful, use the sound one, and reverse the board, which amounts to the same thing. Mark the ulnar and radial borders of the splint so that they can be distinguished.

Round off the ulnar side of the distal end of the splint by cutting away the area A B C (Fig. 2). This gives the ulnar deviation of the hand, as hereafter described.

When the prone forearm and hand lie on a flat surface there is a marked subcarpal hollow. To fill this up, take a piece of three eighths or one half inch board, four inches long for an adult, from two to three inches for children, and round the upper surface longitudinally (Fig. 3). Tack this to the splint so as to fit the hollow of the wrist and trim its sides to fit the contour of the splint. Pad the upper surface of the splint with a double layer of absorbent cotton and cover the whole with a muslin roller (Fig. 4).

Wrap the fractured wrist with a few turns of gauze bandage, and over this take two or three turns of adhesive plaster. Palmar and dorsal pads are not needed. When the splint is applied the thumb lies extended on its upper flat surface and the fingers naturally fall around and clasp the rounded ulnar edge before mentioned, giving moderate, but sufficient, ulnar deviation. Bind on the splint with a gauze roller and a muslin

roller over it. The bandaging is carried down to a line extending between the distal ends of the first and fifth metacarpal bones; with the hand in ulnar deviation, this line will be at right angles to the long axis of the forearm. An ordinary sling is used. Tension of the

bandages must be carefully regulated till swelling subsides, then they are to be tightened and passive motion of the fingers begun. After two weeks, remove the splint to wash the arm, then reapply it for two weeks more. During this latter period slight active motion of the fingers is to be encouraged.

In my practice, this simple device has proved entirely efficient. It can be made in a few minutes, with a saw and pocket-knife, of materials procurable anywhere. And not the least of its advantages is the fact that, being "made to order" for each case, it is always an exact fit, a point not always sufficiently appreciated in the treatment of fractures.

302 SHIPPEN STREET.

American Laryngological Association.—The twenty-third annual congress of the association will be held at New Haven, Conn., Monday, Tuesday, and Wednesday, May 27th to 29th. The president of the congress is Dr. Henry L. Swain, of New Haven.

A REQUISITE TO INCREASE THE USEFULNESS OF AMBULANCES.

By FREDERIC GRIFFITH, M. D.,

NEW YORK,

SURGEON, BELLEVUE DISPENSARY.

THE treatment of shock is one which confronts the ambulance surgeon more often than any other condition in emergency work. True, it is associated with causative factors, but its importance cannot be overestimated so long as early death following accidents is so common from this source. Passing by the internal treatment of shock, of all the external measures employed to combat its action the application of heat is the most valuable.

The following suggestions are made with the object of having this therapeutic agent applied to patients while in ambulances *en route* to hospital.

The construction of ambulances is faulty in that they are too open for use in the freezing weather common to our New York winters. They should be fitted, front and back, with doors made with due attention to light and ventilation-slides, and removable for summer work. By the use of asbestos or some other non-conductor of heat, placed in the frame of the top, bottom, side-walls, and doors the loss of heat would be minimized.

Apparatus suitable for equipping the new models of automobile ambulances will vary according to the motive power. Where steam is used, the exhaust pipe may readily be turned into a coil running along the sides of the interior, and fitted with valves to turn the steam out when not needed. Where electric storage motive power is employed, heat coils similarly fixed—some portable with protected wire connections and kept in racks to be used as are hot-water bags—will be adequate. In the horse ambulances a source of heat must be supplied, and this is readily obtainable by the many forms of car stoves in vogue, and placed under the seat or body of the vehicle, coal being preferable to oil or gas as a fuel on account of its greater safety.

In addition, sand-bags made of canvas, long and narrow, and filled with bar-sand, should be kept constantly hot at the stable by means of a heating-plate attached to the steam pipes or stove in the building. Just before leaving on a "call," three or four may be placed in the ambulance, to be laid beside the patient.

The accompanying physician might well have his place in front, where he could direct the movements of his ambulance, as well as give any needed attention to the patient.

Ambulance calls do not reduce the mortality reports of hospitals; and a measure which, in any degree, will affect the vital statistics of such institutions on the credit side is worthy of serious consideration.

By these means, namely, a thermometer and a heat appliance, fitted to all ambulances, with little cost or

trouble for maintenance, incalculable good would ensue to shocked patients, and especially in those cases which demand immediate operation. Patients would stand a better chance of recovery, and surgeons would often be saved the chagrin of table deaths.

805 MADISON AVENUE.

Therapeutical Notes.

For Superficial Cancerous Growths.—According to *Ἱατρικὴ Πρόοδος* for January, Dr. Hue had employed the following for some time prior to the publication of Czerny's method:

℞ Arsenious acid. 3 grains;
Cocaine. 15 "
Boiled water. 1,500 minims.

M.

From two to three cubic centimetres to be injected daily.

The author has seen many cures with this treatment.

The Aperient Action of the Persulphate and the Metavanadate of Sodium.—*Journal des praticiens* for February 16th says that these drugs seem to have given good results in tuberculosis, probably because of the increase of appetite caused by them. This aperitive action may be utilized in many morbid conditions: simple or tuberculous dyspepsia, cancer of the stomach, etc. M. Robin employs the following formula:

℞ Sodium persulphate. 30 grains;
Water. 9½ ounces.

M.

A soup-spoonful before each of the two principal meals. To be continued for six days and then suspended.

Metavanadate of sodium has the same properties, but is employed in smaller doses:

℞ Metavanadate of sodium. . . $\frac{45}{100}$ ths of a grain;
Distilled water. 4½ ounces.

M.

A coffee-spoonful half an hour before the two principal meals, or $\frac{1}{32}$ d of a grain. The treatment should be suspended at the end of four days.

For Chronic Otorrhœa.—The following is taken from No. 10 of *Medicinische Woche*:

℞ Iodide of potassium. 30 grains;
Tincture of iodine. 6 drachms;
Alcohol. 1 ounce;
Glycerin. 6 drachms;
Iodoform. 30 grains.

M. Sig. Inject into the outer ear.

Salicylate of Methyl for Chordee.—Dr. Baratier (*Journal des maladies cutanées et de syphiligraphie; Gazette hebdomadaire de médecine et de chirurgie*, December 9, 1900) has used the following method with great success in cases of gonorrhœa with painful nocturnal erections. He prescribes hot baths and large doses of Vichy water, followed by injections to the penis for some minutes with the following:

℞ Salicylate of methyl. 15 grains;
Petrolatum. 150 "

The penis is then surrounded with a layer of cotton. Pain is said to disappear very quickly under this treatment.

NEW YORK, SATURDAY, MARCH 30, 1901.

VARICOCELE AS A CAUSE OF DISABILITY.

EXPERIENCED surgeons, we think, must generally have come to the conclusion that varicocele is, in the great majority of instances, more of a blemish than a serious departure from the normal state. But that is not the opinion of the laity, and probably it is not the conviction of the younger members of the profession. The surgeon-general of the army, as we learn from *Circular No. 3*, dated February 27, 1901, adheres to the rule laid down in Tripler's *Manual* for the guidance of medical officers in the examination of recruits. According to this rule, a candidate for enlistment should be rejected if he has a varicocele which is larger than the sound testicle; if, however, after his enlistment has been accepted, he is found to have a varicocele as large as the sound testicle or larger, and complains of disability arising from it, the facts call, not for his discharge, but for surgical treatment of the varicocele. And to this the soldier is compelled to submit under a decision published in *Circular No. 11*, adjutant-general's office, dated December 10, 1884, as follows: "Except in case of a capital operation involving the risk of life, a soldier cannot refuse to submit to medical treatment or surgical operation without subjecting himself to trial by court-martial for wilfully avoiding treatment the purpose of which is to enable him to perform the duties for which he enlisted."

The examination of recruits on a large scale has confirmed even so experienced a surgeon as Dr. Nicholas Senn in his opinion as to the general innocuousness of varicocele. *Circular No. 3* gives extracts from a paper by Dr. Senn in which he states that for years he has been convinced that too many operations were being performed for varicocele, and adds that he has always advised his pupils to restrict operative intervention to the

exceptional cases in which well-marked symptoms independent of sexual neurasthenia fostered by quack literature were present. In the course of a single month, on the outbreak of the Spanish-American war, Dr. Senn had occasion to examine 9,815 recruits for the volunteer service, and he took special pains to investigate varicocele as a cause of disability. He was surprised at the prevalence of the affection—almost one out of every four men between eighteen and thirty years of age had it—and to find that in more than half the cases the men themselves were ignorant of the fact. He found it more frequent in men who were robust than in those of slight build. In most instances the men were otherwise in excellent condition, and atrophy of the testicle was seldom noted. When the varicocele was large, the men were invariably questioned as to the existence of resulting pain or discomfort, and in not more than three or four cases was the reply in the affirmative. Nearly forty years ago the late Dr. Willard Parker declared in a clinical lecture that varicocele generally disappeared at about the age of thirty-five years. We have not been able to substantiate this statement, but we are convinced that at about that age the varicosity, as a rule, ceases to grow more pronounced.

On the other hand, it must be admitted that there are occasional cases of varicocele that call for surgical intervention—not, however, by the crude methods in vogue before the days of antiseptic surgery, such as curtailment of the redundant scrotum and the uncertain subcutaneous ligation of the varicose veins, a procedure in which the spermatic artery and the vas deferens were by no means sure to be spared. All this is convincingly set forth in *Circular No. 3*, in which several medical officers of the army record their experience with the high operation, that, namely, of opening the inguinal canal by an incision an inch and a half long, bringing out the varicose veins, ligating all but one of them *en masse* at the two ends of the incision, and excising the intervening portion. This is an open operation, one easy of performance and sure in its results, without danger of consecutive atrophy of the testicle. Moreover, it involves only the pubic region, one readily rendered aseptic, and not the corrugated scrotum, with its quasi-vermicular contractions, which is uncommonly difficult of sterilization.

A HYBRID OF TYPHOID FEVER AND DYSENTERY.

OF the quick supervention of dysentery upon typhoid fever, or of typhoid fever upon dysentery, there is no

lack of examples, and the expression "typhoid dysentery" figures in medical literature, Aitken, for example, in his *Science and Practice of Medicine*, describing under that appellation a form of dysentery accompanied by some of the phenomena of typhoid fever. But a closer association of the two diseases, one quite as close indeed as that maintained with regard to malarial poisoning and typhoid infection by those who uphold the existence of "typhomalarial fever," has recently been insisted upon by a European military physician, Dr. Paul Remlinger, subdirector of the Imperial Institute of Bacteriology of Constantinople (*Revue de médecine*, March), who gives observations to substantiate those of Torti and those of Kelsch and Kiener. The "fusion" of dothienenteritis and dysentery, he remarks, may be very intimate. The two affections make their appearance simultaneously, and there results a clinical type in which for some time the diagnosis halts between the two.

This hybrid, according to Remlinger, is a very fatal affection, the mortality amounting to fifty per cent. The dysenteric symptoms are the greenish color of the dejecta, straining, tenesmus, and pain and tenderness in the course of the large intestine, while the typhoid symptoms are the course of the temperature, the saburral state, headache, insomnia, and feebleness of the circulation. Post mortem, he says, it has always been easy to distinguish the lesions of dysentery and those of typhoid fever, the first being strictly limited to the large intestine and the second to the small intestine—the lesions do not blend as the symptoms do, although it is conceivable that those of either disease may pass the limit of the ileocæcal valve, giving rise to dysentery of the distal portion of the ileum or typhoid lesions of the large intestine. If this should occur, he adds, it would be very difficult to assign to each infection its true part in the evolution of the disease; but we see no advantage in forecasting the perplexity that might result from an occurrence that has never been observed and, it seems to us, is hardly imaginable.

THE CINEMATOGRAF IN MEDICINE.

In our issue for September 3, 1898, we commented on a suggestion by M. Marcel Baudouin that the cinematograph might with great advantage be employed in the teaching of medicine. M. Baudouin then lamented that the "sinews of war" were not forthcoming to enable him to put into execution his purpose of employing the apparatus in Professor Terrier's laboratory at the Paris

School of Medicine, first, for registering the successive steps in operative procedures, especially with a view to demonstrating how far current practice was at variance with theoretical teaching; and, secondly, "in the study of operations called rapid." Dr. Mount Bleyer, of New York, subsequently informed us that he had presented to the French Academy of Medicine a communication on the subject so far back as February 28, 1895.

The *Indian Lancet* for February 11th of the current year, publishes, however, a translation of a Lecture on the Cinematograph and the Teaching of Surgery (from what source is not mentioned), by Professor E. Doyen, of Paris. At the meeting of the British Medical Association at Edinburgh, so far back as July, 1898, Professor Doyen actually showed three films on the screen, representing, respectively, the manipulation of his operating table, an abdominal hysterectomy, and a craniectomy. The exhibition was regarded as very satisfactory and was repeated by request.

The advantages of the cinematograph include not only demonstrations of actual operations to students in such a way that the whole class can see what, at the operation itself, only a few of those nearest can see, but also a means of bringing before the profession in every part of the world the actual work of its great masters in all countries; the preservation to the future of records such as we would gladly have, were they available, of the prowess of the great surgeons of the past; a permanent visible record of the progress of surgery; and, last, but by no means least, the holding up of a mirror to the operator himself, whereby he can be a looker on at his own work—and "lookers on," as the proverb tells us, "see most of the game." From this he can learn wherein details of technique that have seemed satisfactory are defective, how deficiencies in his method may be supplied, and how redundancies may be lopped off. Professor Doyen states that the hours he has spent with M. Clement Maurice and with his own assistants, studying his technique with the help of the cinematograph, have been of the greatest interest and value to him.

The nurse, too, and the anæsthetist can learn much by seeing themselves as the cinematograph makes them appear. Even the general public, Professor Doyen thinks, might materially benefit, in these days when all classes of society follow with such keen interest the progress of surgery, by the use of other means of getting information than the absurdly inaccurate and misleading statements that the daily press will continue to

spread abroad. "Those who have seen operations as shown by the cinematograph," says M. Doyen, "admit that the calmness of the surgeon, the precision of his movements, and the perfection of the operative technique tend to diminish, rather than increase, the unknown horrors of an operation."

Professor Doyen states that since the meeting at Edinburgh he has added to his collection of films, which will be issued in a few months for use in the teaching faculties, each film being accompanied with a full description, clinical and pathological; and he adds that surgeons who may wish to use the cinematograph themselves, whether in operating or in teaching, are welcome to ask him for any details that may spare them errors or expense.

THE UNIVERSITY OF PENNSYLVANIA MEDICAL BULLETIN.

THIS is the new title of the *University Medical Magazine*, beginning with the first number of Volume xiv, and a far more appropriate title than the old, since it is distinctive. The periodical has been changed in form as well as in name, having large, double-columned pages, fewer in number. It is edited by Dr. Charles H. Frazier.

THE REDUCTIO AD ABSURDUM OF SPECIAL LEGISLATION.

ASSEMBLYMAN SCHNEIDER, of the county of Erie, is reported as having said recently that two of his friends had told him that a certain citizen of Buffalo, a Mr. Vogelgesang, "had discovered a peculiar remedy by which he said he had effected many cures of rheumatism," and that in their opinion he ought therefore to be licensed to practise medicine. Accordingly, Mr. Schneider introduced into the Assembly of the State of New York a bill given to him by his two friends authorizing the said Vogelgesang to practise medicine, "except of [*sic*] surgical operations and narcotic remedies." Even legislators, let us hope, are likely soon to see the absurd and dangerous character of some of the bills they good-naturedly undertake to father.

THE SANITARY CONDITION OF HAVANA.

THE report of Major W. C. Gorgas, surgeon United States army, chief sanitary officer of Havana, is calculated to arouse feelings of considerable satisfaction, as evidencing the benefits conferred, not only upon Cuba itself, but also upon the world in general and this continent in particular, by the American administration of the city, for the world at large is a gainer by any ad-

ministration of any country which reduces the foci of infectious disease. Yellow fever has now been reduced to the eighth place on the mortality list as a consequence of the vigorous and effective sanitation in force, and its further reduction may be confidently looked for. That the disease has occurred principally among "white males" is explained by the fact that a large proportion of the inhabitants are foreign immigrants, who are almost entirely of the male sex, causing the male population of the city to be greatly in excess of the female.

SAUSAGE POISONING ON A LARGE SCALE.

A NOTEWORTHY instance of sausage poisoning affecting a large body of men is recorded by Pfuhl (*Zeitschrift für Hygiene und Infektionskrankheiten*, xxxv, 2; *Wiener klinische Wochenschrift*, February 21st). Eighty-one soldiers fell ill with symptoms of acute gastric catarrh after having eaten "Rinderwurst" the day before. Chemical examination revealed nothing positive, but there was found a species of *Proteus* which, administered to mice and rats, produced death.

THE MORTALITY OF MEDICAL TUTORS.

STATISTICIANS, as is well known, do not accord great length of years to the members of our craft. Few if any of us are greatly perturbed over this fact; indeed, we take but a mild interest in the figures that are now and then published. Among the most recent are those promulgated by Moeglich, of Berlin (*Deutsche Aerzte-Zeitung*, 1900, No. 22; *Wiener klinische Wochenschrift*, February 14th), who finds, not only that the mortality of physicians is high, but that it is highest among *Docenten*. What young man, however, will hesitate to become a *Docent*?

THE LOW TEMPERATURE OF THE GOORKHA.

THE bodily temperature in a state of health is generally accepted as among the most constant of physiological phenomena. It seems, however, that the normal temperature of the Goorkha Sepoy is below that of the generality of mankind. In the February number of the *Indian Medical Gazette* this fact is set forth by N. P. O'G. Lalor, M. B., B. Ch., a captain in the British Indian Medical Service. Captain Lalor, reasoning that this must be due to defective metabolism, tested his theory by administering sugar, about six ounces daily, for a period of eleven days, to six healthy men of a Goorkha regiment. Their average temperature for eleven days preceding the administration of the sugar was 97.1° F., for the period of its administration 97.4°, and for the eleven days following the cessation of the saccharine treatment 97.2°. The temperature rose in every case during the period of feeding with sugar.

News Items.

Society Meetings for the Coming Week:

MONDAY, April 1st: New York Academy of Medicine (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association (annual); Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society (annual).

TUESDAY, April 2d: New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Broome (quarterly) and Niagara (quarterly), N. Y.; Essex (annual), Hudson, and Union (annual), N. J., County Medical Societies; Androscoggin, Maine, County Medical Association (Lewiston); Chittenden, Vermont, County Medical Society; Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, April 3d: New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y. (New Brighton); Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, April 4th: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Washington, Vermont, County Medical Society; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, April 5th: Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, April 6th: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending March 23, 1901:

- BOGERT, E. S., Medical Director, retired. Detached from the marine recruiting rendezvous, New York, and ordered home.
- BRANSFORD, J. F., Surgeon. Retired in accordance with the Act of Congress, approved February 5, 1901.
- CRAWFORD, M. H., Surgeon. Detached from the marine recruiting rendezvous, Buffalo, and ordered to the marine recruiting rendezvous, New York.
- GROVE, W. B., Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to the Naval Hospital, Norfolk, Virginia.
- HAAS, H. H., Assistant Surgeon. Ordered to the Naval Hospital, New York.
- HIGH, W. E. G., Assistant Surgeon. Detached from the Oregon and ordered to the Kentucky.
- LEACH, P., Surgeon. Detached from the Oregon and ordered to the Monocacy.
- MARMION, R. A., Medical Director. Detached from the Naval Home, Philadelphia, and ordered to the Washington Navy Yard, as president of the examining boards.
- MOORE, J. M., Passed Assistant Surgeon. Detached from Port Royal Naval Station and ordered to the Franklin.
- ORVIS, R. T., Assistant Surgeon. Detached from the Adams and ordered to the Naval Hospital, Mare Island, California.
- PARKER, J. B., Medical Director. Detached from duty as president of medical examining boards, Washington, and ordered to the Naval Home, Philadelphia.
- RODMAN, S. S., Assistant Surgeon. Detached from the Naval Hospital, Mare Island, California, and ordered to the Adams.

SHIFFERT, H. O., Assistant Surgeon. Detached from the Franklin and ordered to the Solace for duty at the Asiatic Station.

THOMPSON, E., Assistant Surgeon. Detached from the Nashville and ordered to the Solace upon arrival in Asiatic waters.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera and plague were reported to the surgeon-general during the week ending March 23, 1901:

Small-pox—United States and Insular.

Washington, District of Columbia.....	Mar. 2-16.....	10 cases.	
Jacksonville, Florida.....	Mar. 9-16.....	4 cases.	
Chicago, Illinois.....	Mar. 9-16.....	8 cases.	
Terre Haute, Indiana.....	Feb. 4-11.....	2 cases.	
Wichita, Kansas.....	Mar. 8-16.....	15 cases.	
Lexington, Kentucky.....	Mar. 8-16.....	1 case.	
New Orleans, Louisiana.....	Mar. 8-16.....	14 cases.	4 deaths.
Baltimore, Maryland.....	Mar. 8-16.....	1 case.	
Bay City, Michigan.....	Mar. 8-16.....	2 cases.	
Detroit, Michigan.....	Mar. 8-16.....	4 cases.	
West Bay City, Michigan.....	Mar. 1-16.....	1 case.	
Minneapolis, Minnesota.....	Mar. 2-16.....	11 cases.	
Winona, Minnesota.....	Mar. 8-16.....	26 cases.	
Omaha, Nebraska.....	Mar. 2-9.....	5 cases.	
Manchester, New Hampshire.....	Mar. 8-16.....	3 cases.	
Elmira, New York.....	Mar. 2-9.....	1 case.	
New York, New York.....	Mar. 8-16.....	37 cases.	6 deaths.
Cleveland, Ohio.....	Mar. 8-16.....	46 cases.	
Toledo, Ohio.....	Mar. 2-16.....	3 cases.	
Erie, Pennsylvania.....	Mar. 8-16.....	1 case.	
McKeesport, Pennsylvania.....	Mar. 8-16.....	3 cases.	
Pittsburgh, Pennsylvania.....	Mar. 8-16.....	2 cases.	
Steeltown, Pennsylvania.....	Mar. 8-16.....	5 cases.	
Memphis, Tennessee.....	Mar. 8-16.....	20 cases.	
Nashville, Tennessee.....	Mar. 8-16.....	14 cases.	
Salt Lake City, Utah.....	Mar. 2-16.....	97 cases.	
Aguas Buenas, Porto Rico.....	Feb. 8—Mar. 5.....	2 cases.	
Bayamon, Porto Rico.....	Feb. 8—Mar. 5.....	2 cases.	
Caguas, Porto Rico.....	Feb. 8—Mar. 5.....	2 cases.	
Ciales, Porto Rico.....	Feb. 8—Mar. 5.....	2 cases.	
Morovis, Porto Rico.....	Feb. 8—Mar. 5.....	2 cases.	
Ponce, Porto Rico.....	Feb. 8—Mar. 5.....	98 cases.	1 death.
Quebradillas, Porto Rico.....	Feb. 8—Mar. 5.....	4 cases.	
Rio Piedars, Porto Rico.....	Feb. 8—Mar. 5.....	1 case.	
San Juan, Porto Rico.....	Feb. 8—Mar. 5.....	7 cases.	
Manila, Philippines.....	Jan. 29—Feb. 9.....	11 cases.	

Small-pox—Foreign.

Pernambuco, Brazil.....	Jan. 17-31.....		25 deaths.
Rio de Janeiro, Brazil.....	Feb. 16-28.....		36 deaths.
Bracebridge, Canada.....	Mar. 2.....	2 cases.	
Georgian Bay, Canada.....	Mar. 2.....	Prevalent.	
Orillia, Canada.....	Mar. 2.....	1 case.	
Penetanguishine, Canada.....	Mar. 2.....	1 case.	
Toronto, Canada.....	Mar. 2.....	4 cases.	
Cairo, Egypt.....	Feb. 11-25.....		3 deaths.
Paris, France.....	Feb. 8—Mar. 2.....		21 deaths.
London, England.....	Feb. 23—Mar. 2.....	1 case.	
Glasgow, Scotland.....	Mar. 1-8.....	46 cases.	12 deaths.
Bombay, India.....	Feb. 12-19.....		7 deaths.
Madras, India.....	Feb. 9-15.....		5 deaths.
Tuxpan, Mexico.....	Feb. 25—Mar. 4.....		1 death.
Moscow, Russia.....	Feb. 12-23.....	4 cases.	
St. Petersburg, Russia.....	Feb. 16-23.....	3 cases.	
Moscow, Russia.....	Feb. 16-23.....	12 cases.	
Barcelona, Spain.....	Jan. 1—Mar. 2.....		253 deaths.
Corunna, Spain.....	Feb. 23—Mar. 2.....		1 death.
Valencia, Spain.....	Feb. 8-24.....	1 case.	

Yellow Fever.

Havana, Cuba.....	Mar. 4-11.....	1 case.	
-------------------	----------------	---------	--

Cholera.

Bombay, India.....	Feb. 12-19.....		3 deaths.
Madras, India.....	Feb. 9-16.....		12 deaths.
Singapore, Straits Settlement.....	Jan. 26—Feb. 2.....		10 deaths.

Plague.

Cape Town, Africa.....	Feb. 16-26.....	44 cases.	6 deaths.
Bombay, India.....	Feb. 12-19.....		897 deaths.
Manila, Philippines.....	Jan. 19—Feb. 9.....	7 cases.	4 deaths.
Singapore, Straits Settlement.....	Jan. 26—Feb. 2.....		1 death.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from March 16 to March 23, 1901:

- BAILEY, GUY G., Captain and Assistant Surgeon, will proceed to the Presidio of San Francisco for temporary duty.
- BRATTON, THOMAS S., Captain and Assistant Surgeon, will

report to the commanding officer of the transport *Indiana* for duty in charge of convalescents and sick while *en route* to San Francisco, and return to this division.

CARR, LAWRENCE C., Major and Surgeon, is appointed chief surgeon of the District of Santiago, relieving IRA A. SHIMER, First Lieutenant and Assistant Surgeon.

GRISWOLD, RICHARD S., First Lieutenant and Assistant Surgeon, will proceed to Manila and report to the president of the Army Medical Board for examination for appointment as assistant surgeon.

PLUMMER, GEORGE R., Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.

WILLIAMS, ADRIAN D., Acting Assistant Surgeon, will report to the commanding officer, First Battalion, Eleventh Infantry, at Fort Columbus, N. Y., to accompany that battalion to the Philippine Islands.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending March 23, 1901:

DISEASES.	Week end'g Mar. 16.		Week end'g Mar. 23.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	19	10	23	5
Scarlet Fever.....	608	29	607	40
Cerebro-spinal meningitis.	0	5	0	4
Measles.....	234	6	316	4
Diphtheria and croup.....	324	58	300	59
Small-pox.....	37	6	41	6
Tuberculosis.....	327	189	278	165

A Reception to Dr. Charles L. Dana was tendered by the Medical Club of Philadelphia, at the Hotel Bellevue, on the evening of March 29th.

New York School of Clinical Medicine.—Dr. Heinrich Stern has been elected professor of internal medicine at this institution.

Change of Address.—Dr. John Milton Holt, from the United States Marine-Hospital Service, Cairo, Illinois, to the United States Marine-Hospital Service, Chicago.

The First Woman Medical Graduate of Peru is said by the *Woman's Medical Journal* for February, on the authority of the *Cronica medica*, of Lima, to be Señorita Laura Rodriguez, who graduated in 1900.

The American Congress of Tuberculosis.—The second annual meeting of the American Congress of Tuberculosis will be held at the Grand Central Palace on May 15th and 16th, in joint session with the Medical Society of New York. A dinner will be given for the members and guests.

The Date of Trial Set for the Bellevue Hospital Nurses.—Clinton L. Marshall and Edward O. Dean, the Bellevue nurses under indictment for manslaughter in connection with the death of Louis J. Hilliard in the insane pavilion of Bellevue Hospital, will be placed on trial on the first Monday in May.

Another Attempt Made to Burn a Pest House.—The new isolation hospital at Mason City, Iowa, which would have been ready for occupancy in a few days, was set on fire recently. Owing to the damp condition of the material the loss was not heavy. The city council has offered a reward of \$2,000 for the arrest or apprehension of the criminal.

The Russian Student Riots Affect the Women Medical Students.—As a result of the recent student riots at St. Petersburg, Russia, all the higher courses for women in the Medical Institute of the University of St. Petersburg have been closed indefinitely by official orders.

The State Commission Lunacy Bill a Law.—Governor Odell, of New York, has signed Senator Brackett's bill providing that the president of the State commission in lunacy shall be a physician of ten years' experience, who has had five years' experience in the treatment of mental and nervous diseases or two years' experience in the treatment of committed insane.

The Milwaukee Medical Colleges Seek Tax Exemption.—In the Wisconsin legislature the Assembly committee on assessment and collection of taxes is considering the matter of exempting from taxation the real estate of medical colleges in first-class cities. Under the present law the Milwaukee Medical College's property is exempt. There is another college in Milwaukee—the Physicians and Surgeons'—which does not come under the law.

An Addition to the Medical Building of McGill University.—Another large addition is to be made to the medical building of McGill University at Montreal, Ont., which, when completed, will greatly increase the lecture room and laboratory accommodation of the building. The addition will take the form of a wing. It will be four stories in height, with suitable basement, and will contain a large number of lecture theatres, museums, and chemical laboratories.

A Syrian Doctor Gets an Army Appointment.—Dr. Najib Said Taqy-ud-Din, who took his degree at the Maryland University last year, has been appointed acting assistant surgeon in the United States army and stationed at Columbus Barracks, Ohio. The Protestant Syrian College annually sends to the Maryland University two or three students. Dr. George D. Anawati, who is also a Syrian and who graduated with Dr. Taqy-ud-Din, returned to the Orient and is now practising his profession in Egypt.

Minnesota Prohibits the Marriage of the Insane, the Epileptic, and the Idiotic.—The State Senate of Minnesota has passed Senator Chilton's bill prohibiting the marriage of insane, epileptic, and idiotic persons and requiring a medical certificate for all applicants for marriage licenses. Amendments were adopted making the physician's certificate not quite so sweeping as they had been originally and to permit the marriage of any feeble-minded person over forty-five, the bill originally having extended such permission only to women.

The Bell Bill Dead.—On the motion of the author, the Bell bill, which was drawn up by a committee of the New York Academy of Medicine, with a view to preventing the illegal practice of medicine by Christian Scientists and similar charlatans, was laid aside in the Senate of the New York legislature. This is looked upon as a virtual admission that if pressed to a vote the measure would be defeated. It is possible, however, for the bill to be called up and passed later. The adherents of Christian Science regard the action taken by Senator Bell as an admission of defeat.

Commencement Exercises.—One of the first of the medical colleges to close the student year is the Medico-chirurgical College of Kansas City, Mo., the commencement exercises of which took place on March 20th. The graduating class numbered fourteen. The faculty address was delivered by Dr. J. M. Lansdale.—Forty-three students graduated from the Kansas City Medical College on March 22d, attending the annual college dinner in the evening.—The graduating exercises of the Woman's Medical College at Kansas City were held on March 21st, the class numbering nine.

New York City's Ice Crop Contaminated.—A menace to the health of New York was proclaimed at the meeting of the Manufacturers' Association, Brooklyn, on March 18th, in the report of Professor William P. Mason, who declared that the ice supply coming from the Hudson River above Albany was contaminated with sewage. Professor Mason was engaged some time ago by the association to investigate the purity of the ice. He presented a map of the Hudson River between Cohoes and Albany. This district, he said, contained from sixty-five to seventy icehouses, and ice taken from below the juncture of the Hudson and the Mohawk contained the *Bacillus coli*, showing the presence of sewage. Professor Mason said that the sewage of many towns and cities entered the river along this stretch, and it was inevitable that contamination of the water and ice should follow. After some discussion a resolution was adopted asking the State board of health to investigate the report.

Leprosy in the Philippines.—Marine-Hospital Surgeon Perry, chief quarantine officer for the Philippines, has forwarded to Washington an official report on leprosy in the Philippines. He says: "Leprosy is widely prevalent over the entire archipelago, but the greatest number of cases exists in southern Luzon and the southern islands. It is quite prevalent in Cebu, the number of lepers being estimated at 2,000. The total number of cases in the islands is estimated at 20,000. The cases in Manila and surrounding country are isolated in a substantial hospital, under the auspices of the Manila board of health. There is also a leper hospital at Cebu. An attempt at segregation and isolation of the lepers in the islands has been made by the army officials, and several months ago orders were issued directing that a hospital in each district be set aside for the isolation of the lepers, and a board of army officers was detailed recently to investigate several islands for the purpose of selecting a suitable one for a leper colony."

Foreign University News.—Professor Anton Freiherr von Eiselsberg, of Königsberg, has been selected to succeed the late Dr. Édouard Albert as professor of surgery at Vienna. Professor Eiselsberg studied under Billroth and has held professorships at Utrecht and Königsberg, and has been a frequent contributor to surgical literature.—Professor Albrecht Kössel, of Marburg, has been nominated professor of physiology in the Heidelberg University.—Dr. Yewetzky, of Moscow, has been nominated professor of ophthalmology at the University of Dorpat.—On the 14th of January the new dermatological clinic was opened at Leipzig. The lecture hall has seats for eighty-two students, and contains all the latest forms of projection apparatus for demonstration.—Dr. Andreas Michel has been chosen to act as director of the dental institute, which was formerly a private institution, but which has been in-

corporated into the University of Würzburg.—Dr. J. Fibinger has been nominated professor of pathological anatomy at Copenhagen, caused by the death of Professor Lange.—Dr. P. A. Minakow has been made extraordinary professor of legal medicine at the University of Moscow.

Foreign News Notes.—Dr. Franziska Tiburtius, the oldest female practitioner of medicine in Berlin, recently celebrated the twenty-fifth anniversary of her graduation as doctor of medicine. She studied at Zurich from 1871 to 1876, and for half a year was with Professor Winckel at Dresden. She has practised in Berlin ever since 1877.—Professor Grassi has received the decoration of the Order of the Golden Crown from the Society of Italian Agriculturists in recognition of his valuable work on malaria.—The thirtieth congress of the German Surgical Society will be held in Berlin from the 10th to the 13th of April, the preliminary exercises occurring on Tuesday evening, April 9th, at the "Spartenbrau, 172 Friederich Strasse." The congress will be presided over by Dr. Czerny, of Heidelberg.—Dr. Dubrueil, formerly professor of surgery at Montpellier, is dead.—Dr. Duclos, formerly professor of internal medicine at the University of Tours, died recently.—Dr. Patrick Manson gave a dinner on March 6th to the teachers of the London School of Tropical Medicine, when a testimonial and address were presented by the teachers to Dr. D. C. Rees, who has recently resigned the office of medical tutor of the school.—Professor Nothnagel has been elected an honorary member of the Society for Internal Medicine of Berlin.—Dr. von Heusinger, professor of forensic medicine at Marburg, died recently.—Dr. H. A. Schapiro, one of the most popular physicians of St. Petersburg and a professor in the clinical institute of Princess Helene Palowna, is dead at the age of forty-eight.—During the examination year of 1899-1900 1,384 physicians were licensed, as against 1,364 for the preceding year. The number of licenses to practice issued in 1880-81 was 556, the number rising in 1890-91 to 1,570, and then gradually declining to 1,294 in 1896-97.—The death of Dr. Emil Kammerer, chief physician to the city of Vienna, occurred on March 6th, in the fifty-fifth year of his age. At one time he was private assistant to Dr. Billroth, and contributed many valuable papers to the medical press on hygiene and related topics.

The Nineteenth Congress for Internal Medicine will be held in Berlin from the 16th to the 19th of April under the presidency of Dr. Senator, of Berlin. A large number of leading authorities in medicine have agreed to take part in the proceedings of the association.

The New York Academy of Medicine will meet on April 4th, when papers will be presented on The Duty of the Public to the Medical Profession, by Dr. D. B. St. John Roosa and Dr. W. H. Thomson. Dr. A. H. Smith, Dr. F. R. Sturgis, Dr. A. Jacobi, Dr. F. P. Kinnicut, and others will take part in the discussion of the papers.

Officers Elected by the New York Medico-surgical Society.—At the recent annual meeting of the New York Medical-surgical Society the following officers were elected: President, Dr. Robert A. Murray; vice-president, Dr. A. R. Robinson; member of the executive committee, Dr. W. Duff-Bullard; secretary, Dr. J. Arthur Booth.

The St. Louis Medical Society of Missouri.—At the last regular meeting, on Saturday evening, the 23d inst., the following papers were read: A Preliminary Report of a Case of Total Extirpation of the Stomach, with presentation of specimen, by Dr. N. B. Carson, and The Physiological and Clinical Aspects of Dr. Carson's Case of Gastrectomy, by Dr. Jesse S. Myer.

The Fifth Triennial International Congress of Physiologists will be held at Turin from the 17th to the 23d of next September. The University Institute of Physiology will be used as the headquarters. Professor Sherrington, of the Thompson-Yates laboratories, University College, Liverpool, is the general secretary for the English-speaking countries, and will furnish any information desired as to the programme of the congress.

Medical Experts Discussed at Medico-legal Society Meeting.—Members of the Medico-legal Society declared themselves against the medical expert at the meeting on March 20th, held at the Hotel St. Andrews. R. L. Prichard read a paper registering an emphatic protest against the admission of testimony of experts. Stiles Judson, Jr., of the Bridgeport bar, read a paper on Law and Medicine, and Amnesia was the subject of an essay by L. J. Rosenberg and N. E. Aronstam, of Detroit.

The American Laryngological, Rhinological, and Otolological Society, which, as announced in our last issue, was to meet at the New York Academy of Medicine from May 30th to June 1st, has decided to change the dates of its meeting to May 23d, 24th, and 25th, so as to avoid having the meeting occur on the same dates as have been selected by the American Climatological Society. Those desirous of presenting papers should lose no time in forwarding the titles to the secretary, Dr. Wendell C. Phillips, 350 Madison Avenue, so that he may be able to include them in the printed programme.

The Kings County Medical Society.—The Medical Society of the County of Kings, at a recent meeting, listened with interest to several addresses under the head of The Scope and Support of Hospitals. Dr. John Harrigan spoke on The Advantages to the Public and to the City of the Non-municipal Hospital. Dr. J. T. Duryea spoke on the subject *City versus Independent Hospitals*, and other speakers were Dr. A. C. Bunn, who spoke on Church Hospitals, and Dr. W. M. Hutchinson, who spoke on Municipal as Compared with the Private Care of Infants and Children. After the several addresses had been made there was a discussion of the subject in general by Dr. A. S. Ambler, Dr. F. Weisbrod, Dr. W. C. Wood, Dr. J. M. Van Cott, and others.

The Medical Society and its Work of Reforming New York's Milk Dealers.—The milk commission of the Medical Society of the County of New York held a meeting on March 20th at the New York Academy of Medicine. Notices had been sent to all milk dealers in the city, inviting them to be present, and about forty were there. Dr. Henry Dwight Chapin, the chairman, explained the proposition which the commission had to lay before the trade, as the result of investigations extending over a considerable period. The other members of the commission are Dr. Walter Lester Carr, Dr. Abraham Jacobi, and Dr. Joseph E. Winters. The commission has decided to give labels to such dealers as sub-

mit their premises to inspection by experts employed by the commission and maintain the required standards.

An International Congress to Discuss Yellow Fever.—Quite an extensive project is likely to take form in a few days for an international congress of representative scientists, sanitarians, and doctors of the United States, Central and South America for the purpose of considering plans for the eradication of yellow fever, not so much by cure as by prevention. The plan took shape recently at the medical congress at Havana, when the Argentine minister at Washington, Dr. Wilde, suggested an international congress of that character. As part of the project, he suggested the raising of a common fund, to be assigned to various localities, to carry on the work of sanitation. He urged that by joint effort of all western countries the disease could be removed entirely. As an instance of this, he cited Buenos Ayres, where a system of sanitation has been adopted which does away with all fear of yellow fever. The medical congress by unanimous vote approved Dr. Wilde's plan, and steps are now being taken for a practical realization of the proposed congress.

The Medical Society of the Missouri Valley.—The thirteenth semi-annual meeting of the Medical Society of the Missouri Valley was held in Omaha, March 21st. In the evening a banquet was given. Dr. V. L. Treyner, of Council Bluffs, is president of the society, and the other officers are as follows: Dr. B. B. Davis, Omaha, first vice-president; Dr. F. E. Sampson, Creston, second vice-president; Dr. T. B. Lacey, Council Bluffs, treasurer; Charles Wood Fassett, St. Joseph, secretary. Papers on medical subjects were read by the following: Dr. A. B. Somers, Dr. J. Cameron Anderson, Dr. J. M. Aikin, Dr. Millard Langfeld, Dr. D. C. Bryant, Dr. J. E. Summers, Jr., Dr. Charles C. Allison, Dr. H. Gifford, Dr. H. P. Hamilton, Omaha; Dr. E. A. King, Blockton, Ia.; Dr. H. D. Jerowitz, Kansas City, Mo.; Dr. C. H. Wallace, Dr. Daniel Morton, Dr. O. B. Campbell, Dr. M. F. Weymann, St. Joseph; Dr. J. W. Kime, Fort Dodge, Ia.; Dr. J. W. Cokenower, Des Moines; Dr. A. L. Wright, Carroll, Ia.; Dr. Inez C. Philbrick, Lincoln; Dr. Emma Warner Demaree, Roca, Neb.

The New York County Medical Society.—Dr. George B. Fowler, president of the New York County Medical Society, announced at the meeting of that organization held at the Academy of Medicine on March 25th, that each member was expected to write a letter to the Assemblyman of his district requesting him to support the Bell bill. Resolutions were adopted protesting against the sanctioning by the legislature of "any measure giving the right to treat disease unless a compliance with the medical laws of the State is a prerequisite." The reason for these resolutions, as stated in the preamble thereto, is the recent introduction of bills legalizing the practice of osteopathy and the giving of the right to treat disease to "a class of masseurs." Dr. William K. Kubin read a paper on The Importance of Aseptic Vaccination. This was followed by a discussion on the same subject by Dr. John H. Huddleston, of the board of health; Dr. George H. Fox, and Dr. Charles W. Allen, all of whom agreed that shields for protecting vaccination sores had done more harm than good, no device having yet been invented which would not irritate the inflamed spot. Dr. Fox suggested the theory that it would be well for physicians to remove vaccination scabs artificially.

The German Medical Society of the City of New York will meet at the Academy of Medicine on Monday, April 1st, when a paper will be presented on *Atonia Gastrica* and a *New Method of Treatment* by Dr. A. Rose. The paper will be discussed by Dr. L. Weber, Dr. K. Dauber, Dr. William M. Leszynsky, and others. A paper will also be presented by Dr. Freudenthal on *Primary Syphilitic Affections of the Nose*.

Measles.—An epidemic of measles in a light form has visited Upper Alton, Ill., where 150 children are reported ill with the disease.

Scarlet Fever.—Stringent measures are being taken by the board of health of White Plains, N. Y., to prevent the spread of scarlet fever, which has broken out there.—Conditions are also reported quite serious at Montreal, Can.

Diphtheria has made its appearance at Philadelphia and at Montclair, N. J. At the latter place the patient was an employe of a dairy, but, after the place had been quarantined, permission was given for the resumption of the sale of milk.

An Epidemic of Mumps Closes a Chicago School.—Mumps were responsible for the closing of two departments in Lake Forest University at Chicago. An epidemic struck these divisions, and when the number of hospital patients reached twenty the trustees decided to close the classes most affected until April 3d, the end of the regular spring vacation. As this announcement was made all the students in these departments packed their trunks hurriedly and left for their homes.

Small-pox.—Several cases of small-pox were reported during the week from St. Francis Hospital in New York city, as well as one or two from Brooklyn. Reports of the epidemic also continue to arrive from various points in Michigan. At Harrisburg, Pa., 750 pupils in the public schools refused to obey the law and be vaccinated, and they were given several days' grace in which to change their minds or else be refused admission to the schools.—Robert Martin, a lace importer of New York, who has recently been discharged from the small-pox hospital on North Brothers Island, has publicly charged the hospital authorities with neglecting and abusing the patients. In order to completely refute the charges the New York city health commission invited representatives from the several daily newspapers to accompany them on a tour of inspection of the island, to be made without any previous intimation to the hospital authorities of the proposed inspection. The tour resulted in a full and complete refutation of the charges, all the reporters testifying to the cleanliness and care exercised in the treatment of patients.—New cases continue to occur in New York city, four having been reported on March 26th, while one, the first, was reported from Staten Island.

The Health of Havana.—The statistics just published by Major W. C. Gorgas, chief sanitary officer of the Department of Cuba, show that the death rate for February in Havana is lower than it has been for any February for which authentic records have been kept. The last February under the Spanish rule, 1898, showed a death rate of 82.32 per 1,000, while statistics for last February, the third February under American rule, show a rate of 19.32 per 1,000, a figure which is lower

than that for January in several American cities, including Baltimore, Cincinnati, Jacksonville, Newark, New Orleans, New York, and Washington. In many of these the death rate ranges up to from 25 to 29 per 1,000. Major Gorgas is very sanguine as regards the future of Havana so far as yellow fever is concerned, and says that Havana now has a lower death rate than the Gulf cities generally and that he thinks it probable that within a year or two Havana will have to take steps to protect itself from infection from American cities. In February, 1900, seventeen new cases of yellow fever occurred in Havana, and in February, 1901, only eight new cases occurred, notwithstanding the fact that the number of non-immunes present in the city was very much larger this year than last. Besides disinfecting the houses with formalin and other disinfectants, the authorities now screen the rooms occupied by yellow fever patients, kill all the mosquitoes in the building with the fumes of pyrethrum powder, and cover with kerosene oil all places about the building where mosquitoes can breed, and also kill all the mosquitoes in all adjoining buildings. It is hoped by vigorous prosecution of these measures to markedly decrease the yellow fever during the coming summer.

Munificent Gift to an English Hospital.—The heir to the late Lord Armstrong, inventor of the Armstrong guns, has given five hundred thousand dollars to the Victoria Jubilee Infirmary at Newcastle-on-Tyne.

Hospital Appointment.—Dr. George R. White, formerly of Southampton, L. I., has been appointed to a position in the clinic of the Woman's Hospital in New York. Dr. White returned a short time ago from the Philippines, where he was with the army as surgeon.

The Last of St. Luke's Hospital Site Sold.—Judge McAdam, of the Supreme Court of New York, has granted authority to the officials of St. Luke's Hospital to sell the remaining five lots of land on the southwest corner of Fifth Avenue and Fifty-fifth Street, the last of the original plot of thirty-two lots on the old site of the hospital, for \$575,000. According to the petition upon which authority was given to make the sale, the market value of the remaining real estate of the hospital is \$2,326,000, while the cash value of its personal assets is placed at \$1,180,260. The debts and liabilities are about \$5,000.

Proposed Change in Administration of New York Hospitals Abandoned.—The Senate committee on cities in the New York legislature has agreed to strike out of the proposed amendments to the charter of the city of New York that section which recommended that Bellevue and the allied hospitals, viz., Fordham, Harlem, Gouverneur, and the Emergency Hospital, be placed under the administration of a board of seven trustees, the board to be so appointed that the term of office of one member of the board would expire each year. These trustees were to be appointed by the Mayor, but provision was made that certain societies should have an opportunity to make nominations for these appointments. The power of the Mayor to make the appointments was, however, in no degree abridged. The action of the committee in striking out this amendment is practically final, so far as this session of the legislature is concerned, as it will prevent its consideration by the legislature.

An Emergency Hospital for the Pan-American Exposition has been erected near the west end of the mall at the exposition at Buffalo. The hospital, which is for the most part but one story in height, has a frontage of 90 feet on the mall, and the main wing has a depth of 38 feet. The exterior walls are finished in bright colors and the general architectural effect is that of a low, adobe mission house. The interior fittings of the hospital are thoroughly up to date, comprising an office with telephone and electrical annunciators, etc., two male wards with seven cots each, a woman's ward with twelve cots, bath-rooms, linen closets, offices and quarters for the nurses, physicians, etc.; waiting-rooms, kitchen, pantry, and dining-rooms, stables for the electric ambulances and for a gasoline motor ambulance. Dr. Roswell Dark is the director, Dr. Vertner Kenerson is deputy director, and Dr. Alexander Allen is the resident physician of the hospital. Up to March 1st, 504 cases had been treated on the grounds, of which only one was fatal. During the Omaha Exposition about 3,000 cases were treated, and during the World's Fair in Chicago 11,602 cases were cared for in the hospital, in 69 of which death occurred.

Hospital Buildings and Endowments.—A bill has been introduced in the House by Dr. Hemsted, of St. Paul, Minn., for the building of a sanitarium for consumptives. An appropriation of \$150,000 is asked, and also a site somewhere in the pine regions of the State. —The new German Hospital at Buffalo, N. Y., was to be opened for the reception of patients in March. The hospital has ward accommodations for seventy patients and private rooms for twenty-five more. —Residents of that neighborhood in Albany where the proposed new Hospital for Imbeciles is to go up are agitating the question of the selection of a new site. —At a recent meeting of the board of directors of the Montefiore Home for Chronic Invalids in New York, the title and charter of the institution were changed to the Montefiore Hospital for Chronic Diseases. The only reason given for the change of title is that many people misconstrued it and believed the institution to be a home. —Rose Hawthorne Lathrop has conveyed the property at 426 Cherry Street, New York, to the Society for the Relief of Incurable Cancer, a corporation recently formed under the laws of New York. The deed specifically recites that the corporation shall use the premises only as a free home for poor persons suffering from cancer. If it becomes impracticable to use it for this purpose, the directors can sell the property and devote the proceeds to the purchase of other property for similar use. —The Platt Pavilion, the latest addition to the New York Eye and Ear Infirmary, just erected to the memory of James N. Platt, through the munificence of the family of the late Justin A. Bliss, has been practically completed, and was opened for public inspection on February 20th. A feature of the building is isolated wards for the treatment of cases of contagious ophthalmia. —The Post-Graduate Medical School and Hospital, New York City, has received an anonymous gift of \$15,000. —Plans have been drawn for a \$50,000 hospital to be built at Oshkosh, Wis., by a stock company, of which Dr. C. W. Oviatt is at the head. —The New York State senate finance committee has reported favorably the bill appropriating \$120,000 for a tuberculosis hospital in the Adirondacks. —The new fireproof addition to the Lutheran Hospital at St. Louis has been opened. Its cost was \$25,000. —Ground has been broken for the addition to the National Jewish Hospital for Consumptives at Den-

ver, Col. —In the annual report of the superintendent of the City and County Hospital of St. Paul, Minn., he recommends the erection of a new building for a hospital for contagious diseases at a cost of \$20,000 to \$30,000. —The movement to convert the Marcella Street home property in Boston into a home for consumptives has aroused some opposition on the part of citizens residing in the neighborhood. A motion to appropriate \$40,000 for the repairs required should the home be used for consumptives has been introduced in the Boston common council. —Among the last of the measures enacted by the expiring congress were the Sundry Civil bill, which embraces the following appropriations: For support of the Government Hospital for the Insane, \$338,000; for Providence Hospital, \$50,000; for Garfield Hospital, \$19,000; for laboratories for the Department of Agriculture, \$200,000. —In the report of the Brooklyn and Queens (N. Y.) Charities Department for the last quarter of 1900 General Medical Superintendent J. T. Dur-yea comments upon the pressing need of a separate institution in Brooklyn for the cure of alcoholic patients. —A seven-story hospital building will be built by the French Benevolent Society at Nos. 450, 452, 454, and 456 West Thirty-fourth Street. It will cost \$400,000, the greater part of which sum, it is said, has already been raised. The present home of the institution is at Nos. 320 and 322 West Thirty-fourth Street. It is expected that the new home will be ready for occupancy in about a year. —The contract for the foundation work of the new City Hospital at St. Louis, Mo., has been awarded, and work will soon be begun. —It has been decided to erect two additions to St. Francis's Hospital, Cincinnati, O., to cost \$10,000, and to be devoted to patients suffering from cancer.

Births, Marriages, and Deaths.

Married.

BROWN—POOLE.—In St. Louis, on Wednesday, March 13th, Dr. Arthur C. Brown, of New York, and Miss Annie L. Poole.

CAPLES—STELLE.—In Milwaukee, on Saturday, March 23d, Dr. Byron Caples, of Waukesha, Wisconsin, and Miss Grace Harriet Stelle.

HOLMAN—TIMMERMAN.—In St. Clair, Minnesota, on Thursday, March 14th, Dr. Carl Holman and Dr. Endora Madge Timmerman.

LEWIS—LANDFEAR.—In Brooklyn, on Thursday, March 21st, Dr. Stuart Lewis and Miss Jennie Campbell Landfear.

Died.

BOWEN.—In Fort Monroe, Virginia, on Tuesday, March 12th, Dr. Charles H. Bowen, aged sixty-five years.

BURGE.—In Brooklyn, on Sunday, March 24th, Dr. John Henry Hobart Burge, in the seventy-eighth year of his age.

CHAPMAN.—In Birmingham, Alabama, on Saturday, March 23d, Dr. George C. Chapman.

EWING.—In St. Louis, on Saturday, March 16th, Dr. James A. Ewing, in the thirty-third year of his age.

FRASER.—In Philadelphia, on Thursday, March 21st, Dr. Edward Clarence Fraser, in the sixty-first year of his age.

HESS.—In New York, on Sunday, March 24th, Dr. Ralph J. Hess, in the twenty-seventh year of his age.

LOVEJOY.—In Washington, on Monday, March 18th, Dr. James W. H. Lovejoy, aged seventy-six years.

MEDILL.—In Denver, on Thursday, March 14th, Dr. W. W. Medill, in the thirty-third year of his age.

VALENTINE.—In Brooklyn, on Friday, March 22d, Dr. Richard K. Valentine, in the forty-sixth year of his age.

WREN.—In New York, on Saturday, March 23d, Dr. George W. Wren, of Bridgeport, Connecticut, in the twenty-seventh year of his age.

Pith of Current Literature.

Journal of the American Medical Association, March 23, 1901.

Elbow Fractures and the X-ray. By Dr. W. W. Grant.—The author believes that the only tenable conclusion is that the skiagraph should never be used as the determining factor in regard to the existence and pathology of fractures, but may be, in honest and capable hands only, used to supplement or confirm opinions reached without it.

General Bodily Resistance as a Factor in Nose and Throat Disease. By Dr. Frank Louis Stillman.—The author lays stress upon the harmfulness of treating the local remedy alone, and he makes a plea for a more intelligent general treatment. The specialist should always remember that he is physician first and specialist afterward.

Systemic Factors in Catarrhal Deafness. By Dr. Sargent E. Snow.—Among these systemic factors, upon which the author lays particular stress, are, (1) a sluggish skin reaction; (2) low vital forces; (3) torpid liver; and (4) a lack of proper exercise. The author's experience has taught that failure to improve the hearing power means a fault either in the patient or in the physician, and not in the local ear condition. A knowledge of hygienic care and how to increase bodily resistance is a distinct obligation upon the otological specialist.

Diagnosis and Prognosis of Ear Disease. By Dr. B. Alexander Randall.—The author, while advising the possession of a more complete armamentarium for the aurist, is careful to add that it is the eye and the hand behind the instrumental aids that constitute the real means of diagnosis, and that "special" training is by no means essential if a true physician, with gentle hand and observing eye, undertakes these studies.

Effect of Alcohol on the Nervous System, the Mind, and Heredity. By Dr. Albert E. Sterne.—If the true import of the alcohol question were understood, and a proper conception of the effect of alcohol on the physical and mental qualities were gained, the author believes that few generations would pass before we should find, in place of our institutions for restraint and punishment, hospitals for the cure and care of a class of patients more ill, often, than those whom we generally regard as sick or diseased.

A Case of Combined Gastric and Aural Vertigo, with a Discussion of the Pathology of such Cases. By Dr. G. W. McCaskey.

Heart Tonics. By Dr. John N. Upshur.—The author discusses in particular those agents which, under a strict classification, are to be considered as cardiac depressants, but yet are, in the broadest sense, indirect heart tonics, because they regulate heart action. It is not a new thing to see digitalis given to relieve a patient suffering from disturbed heart action, excessive in tension because of hypertrophy, when really it is emphatically contra-indicated, and the truest tonic is an agent like aconite, nitroglycerin, or veratrum viride, belonging to the class of pronounced motor depressants.

The Therapeutic Application of the Organic Extracts. By Dr. O. T. Osborne.

Treatment of Addison's Disease. With Case. By Dr. John V. Shoemaker.—The use of suprarenal extract is advised, though the author doubts its efficacy in cases

in which the tuberculous process is advanced or active. The cases in which organotherapy is useful are probably those in which there is a certain amount of atrophy, sclerosis, or inflammatory alteration, but in which a portion of the gland or glands is still functionally potent.

Quantitative Tests for Proteolysis. By Dr. A. I. Benedict.

Anastomosis of the Ureters with the Intestine. A Historical and Experimental Research. By Dr. Reuben Peterson (*concluded*).—The primary mortality of uretero-intestinal anastomosis, both in experimental work on animals and in man, is exceedingly high. All efforts to prevent ascending renal infection in animals or in man, where the ureter has been implanted without its vesical orifice, have proved futile, and the author concludes that this operation is unjustifiable. The results of uretero-intestinal anastomosis through the formation of a vesicorectal fistula have not been favorable thus far. The primary mortality of uretero-trigono-intestinal anastomosis is low for an operation of this magnitude; and, while it cannot be denied that ascending renal infection may occur after this operation, the infection, as a rule, is of such a type that the chances of the individual's overcoming it are good. Hence the operation of implanting the vesical flap with its ureteral orifice into the intestine is a justifiable surgical procedure.

Medical Record, March 23, 1901.

1. A Case of Ambulatory Typhoid Fever with Intestinal Perforation. 2. A Case of Traumatic Rupture of the Intestine; Operation; Recoveries. Remarks concerning Operation in Cases of Typhoid Fever with Intestinal Perforation. By Dr. A. A. Berg.—The existence of typhoid fever does not contra-indicate an operation; for typhoid patients bear operation almost as well as otherwise healthy individuals. The repair of a ruptured typhoidal ulcer attended with extravasation should be undertaken so soon after the perforation as the patient can stand the necessary laparotomy and possible eventration. Operation in the preperforative stage is not to be considered, for a local peritonitis does not always signify an impending perforation, nor does perforation always imply extravasation. As we have no means of telling which ulcers will perforate, an operation undertaken to forestall such a perforation is often unnecessary. Extravasation can usually be diagnosed early if strict attention is paid to the recognition of the symptomatology.

Chronic Gonorrhœa and Marriage. By Dr. Ludwig Weiss.—The author's position is that we should give permission to marry to those having had gonorrhœa when, after repeated and careful microscopical examination of slide specimens, and an exhaustive bacteriological and microscopical examination of the threads and of the secretions of the prostate and seminal vesicles, done under the strictest rules and with the aid of Gram's method, the presence of gonococci cannot be demonstrated.

Excision of Aneurysm, with a Report of Two Cases of Femoral Aneurysm so Treated. By Dr. George Ryerson Fowler.—The author believes that excision or ablation of aneurysm will be the operation of choice in all cases in which the diseased condition of the vessel is fairly circumscribed, and advanced inflammatory or other complications rendering the operation extraordinarily difficult, are absent.

Conservatism in the Diagnosis and Treatment of Prostatic Hypertrophy. By Dr. James R. Hayden.—Judging from the recorded histories of the large number of patients now being operated upon, the author believes that their symptoms hardly warrant such heroic methods. He asserts, moreover, that, as a general rule, these patients seem to be advised to undergo immediate operation before having had the benefit of an intelligent and sufficiently long palliative or preparatory treatment. This treatment consists in keeping the urine of as normally acid reaction as possible, both by internal medication and by a properly selected diet. Boric acid or urotropine is efficient when the urine is neutral or alkaline. In the opposite condition, the alkalies, either alone or combined with hyoscyamus, kava kava, triticum repens, or uva ursi, are of use. Hot saline rectal irrigation will relieve painful inflammatory symptoms. Hemorrhoids should always receive prompt and efficient treatment.

Subphrenic Abscess as a Complication in Appendicitis. By Dr. J. McF. Gaston, Jr.

Surgical Treatment of Abdominal Dropsy Following Cirrhosis of the Liver. By Dr. James T. Jelks.—The operation suggested by the author consists of abdominal section, preferably between the umbilicus and the ensiform cartilage, evacuation of the accumulation of fluid, and scraping of the parietal peritonæum with a curette or rubbing off of its epithelium by means of a gauze sponge. The superior portion of the liver and the peritonæum covering the diaphragm are also to be rubbed. The omentum for three or four inches around the incision is then to be stitched to the parietal wall.

Hernia of the Adductor Longus Muscle with Operation. By Dr. Clarence A. McWilliams.

Ichthyol in the Treatment of Deep-seated Inflammations. By Dr. Walter T. Slevin.

A Case of Fatal Stenosis of the Larynx Following Intubation for Papillomata. By Dr. F. L. Wachenheim.

Some Facts Bearing upon the Malarial Problem. By Dr. Richard Waggener.

Tetanus. By Dr. John W. S. McCullough.

Boston Medical and Surgical Journal, March 21, 1901.

Puerperal Insanity. By Dr. Arthur C. Jelly.—The author writes an excellent text-book article upon this subject. He lays especial stress upon prophylaxis, for though the mental symptoms of pregnancy are mild and temporary, and frequently pass off without treatment, he points out that this is not a sufficient reason for neglecting to treat the patient seriously, because many patients pass gradually into a very serious condition, which leads to an attack of insanity and ends in dementia. When the surrounding conditions are ominous, the most perfect hygiene should be established; the digestive and eliminative functions should be attended to, and open-air exercise advised. Excitement should be avoided; sleep is important, but drugs should be avoided. Serious mental disturbance is not to be regarded as an indication for inducing labor.

Meat Ration in the Tropics. By Dr. P. R. Egan.—The author's opinions on tropical dietetics are directly opposed to the opinions expressed by the majority of writers, and he asserts that the theoretically perfect diet will not be found flawless in practice. Nothing is proved from an examination of the dietary of the natives, for, he believes, meat consumption among the natives of hot

climates is limited by their purses, not by their taste. Native beef cooked in the American fashion is not without its ill effects in Puerto Rico, but native beef cooked by the native method is tender and palatable, largely consumed, and productive of the best results. He gives some illustrations of the absurdity of arguing from theory instead of experience, and mentions that cold fat pork, crisped on the outside, is sold as a "bonne bouche" in San Juan.

Bubonic Plague. Report on the Plague in Manila, P. I., from January 1, 1900, to June 30, 1900. By Dr. Joseph J. Curry.

A Case of Retroperitoneal Lymphangeiosarcoma; Operation; Recovery—No Recurrence after Two Years. By Dr. F. B. Lund.—A case which goes to show that not all tumors of malignant appearance and rapid growth are actively malignant. The treatment by the mixed toxins does not, according to the author, seem to have had anything to do with the nonrecurrence in this case; as, owing to its apparent bad effect upon the patient's general condition, the toxins were given only in small amounts and for a comparatively short time.

Vomiting of Pregnancy—Suspension of Pregnant Uterus—Extra-uterine Pregnancy—Operation for Fibroids. Reported by Dr. J. Oswald Vogel. From the service of Dr. Frederick William Johnson.

Philadelphia Medical Journal, March 23, 1901.

The Toxicology of Tellurium Compounds, with some Notes on the Therapeutic Value of Tellurates. By William J. Gies, M. S., Ph. D.—In an interesting article the author points out that tellurates, in quantities not excessive and yet much greater than the therapeutic doses in man, exerts no particularly deleterious effects on the nutritional processes in dogs, even when the administration is continued for a week, although proteid catabolism seems to be slightly stimulated after a time, and secretion of acid in the stomach retarded. The alliaceous odor imparted to the breath seems to be the chief objectionable feature constantly following the use of therapeutic amounts of tellurates.

Some Modern Gynæcological Resources. By Dr. Augustin H. Goelet.

Dejerine-Erb Type of Upper-arm Palsy Following Multiple Neuritis. By Dr. D. J. McCarthy.

A New Treatment for Tuberculous Glands of the Neck with Minimal Scarring, Involving a Method of Sterilizing a Tuberculous Region through the Lymph Channels. By Dr. G. Betton Massey.—The object of the author's method is the destruction of the bacilli by the cataphoric diffusion among them of nascent oxychloride of mercury, developed by the electrolysis of metallic mercury held in contact with a small gold electrode. From observation of two cases reported, the author believes that the germicidal action is not confined entirely to the gland to which the application is made, but that the chemicals deposited in this situation drain downward to the next gland in the chain and favorably influence any infection in these glands.

Strangulated and Gangrenous Hernia, Kelotomy and Laparotomy in Strangulation, External and Internal; Artificial Anus—Enterostomy, Primary or Secondary Resection—Enterectomy, and End-to-end or Lateral Jointing in Gangrenous Hernia. By Dr. Thomas H. Manley. (*Concluded.*)

Medical News, March 23, 1901.

Cerebro-spinal Meningitis (Weichselbaum, Jaeger) Treated by Repeated Lumbar Puncture. By Dr. Henry Koplik.—The author states that the relief brought about by repeated lumbar puncture seems to be in the direction of a diminution of pain and a reduction of those symptoms which may fairly be traced to toxæmia and mechanical pressure. At the same time he points out that the withdrawal of an appreciable amount of any fluid from the spinal canal, which contains bacteria and the toxic products of inflammation, must be beneficial in the long run on the course of the disease. He believes that, in time, this method will take its place with aspiration of the pleural cavity as a curative method.

Drainage in Abdominal Surgery. By Dr. J. W. Long.—The author brings many objections against drainage. He asserts that it is deceptive, that it is not a guarantee against infection, and, in fact, that both gauze and the glass tube constitute an additional source of infection. Observation, he says, will demonstrate that when drainage is not used patients do better. Finally, he asserts that drainage is neither scientific nor workmanlike, and he quotes Joseph Price as saying, "Drainage is an evidence of incomplete work." In a word, when we drain, we do so because we cannot do better.

Vertigo: A Stomach Lesion. By Dr. Martin A. H. Thelberg.—As to the mechanism of *vertigo e stomacho*, the author is of the opinion that three causes are concerned, collectively or separately, to wit: 1. Direct irritation of the gastric branches of the pneumogastric, thence by the lower cervical ganglion to the vasomotor nerves of the vertebral artery which supplies the internal ear. 2. Toxæmia from amulon and other ptomaines. 3. Direct pressure upon the heart through distention of the stomach and intestines by gases. The most satisfactory treatment is the correction of the gastro-intestinal disorder.

An Interesting Case of Splenic Anæmia. By Dr. Herbert Maxon King.—The chief points of interest in this case lie in its evident close relation to splenic leucæmia, on the one hand, and pernicious primary anæmia on the other. The blood examination and the general clinical history, however, demonstrate that the case belongs to the group of obscure toxæmias included under the name of splenic anæmia.

Lancet, March 16, 1901.

The Topographical Anatomy of the Abdominal Viscera in Man. By Dr. C. Addison.—The first of the Hunterian lectures. These lectures embody the results of an inquiry into the topographical anatomy of the abdominal viscera in man. The work falls into two parts, (1) that dealing with the relations of the viscera to the surface of the body; and (2) that dealing with their relations to each other. For obtaining maps of the viscera, the bodies of forty subjects taken consecutively were examined in the fresh state. Maps were drawn on the life-size scale on large sheets ruled in centimetre squares, in which the outlines of the various viscera were progressively filled in. The abdomen was divided vertically by three lines, a median and two lateral lines. The lateral lines were drawn vertically upward through a point midway between the anterior superior iliac spine and the middle line, in a line drawn transversely between the two anterior superior iliac spines. Two transverse lines were drawn, one half way and the other a quarter way, respectively, between the pubes and the suprasternal

notch. At the intersection of these various lines the abdomen was transfixed by fourteen-inch steel pins. The abdomen was then opened and the position and dimensions of the various viscera noted and entered upon the map. In this way a complete map of the superficial and deep points in their relations to the lines of division of the abdomen was obtained, and the outlines of the viscera projected on to the surface. The author reviews the topographical relations of these various lines and points to the various viscera, and reaches the following conclusions: 1. A highly placed stomach is usually associated with a liver placed well up beneath the ribs, and often of small size, and with a highly placed transverse colon, which in most cases, also, is distended. 2. A low position of the stomach—referring to the greater curvature—appears to be especially associated with a liver extending low down into the abdomen and perhaps enlarged, and with a low transverse colon. 3. The liver is clearly chiefly responsible for causing alterations in the level of the pylorus. Allowing for the fact that the part of the liver overhanging the stomach varies considerably in thickness, it appears that mere distention of the stomach, apart from a low position of the liver, is not sufficient to produce material downward displacement of the pylorus.

The Treatment of Tuberculous Peritonitis. By Dr. I. B. Yeo.—The author reports three cases of tuberculous peritonitis in which cures were brought about by the external application to the abdomen of equal parts of iodoform ointment and cod-liver oil, and by the internal administration of a pill containing a quarter of a grain of iodoform and half a minim of creosote. In one case the treatment had to be persisted in for over three months before recovery took place. In another case pleurisy with effusion coexisted with the peritonitis. The cases were all in young people between ten and twenty years of age. The author holds that the iodoform rapidly enters the blood and is continuously eliminated in the secretions, including the secretions into the serous cavities. As these latter secretions do not pass out of the body, they must in time become richly charged with iodine compounds, at any rate sufficiently so to act as antitoxine to the tubercle toxine or as antibacterial to the bacilli. "Antitoxines" are not limited to animal products; the oldest and surest antitoxines we possess are mercury and quinine—one from the mineral, the other from the vegetable kingdom. Their effects are better known, more certain, and more reliable than those of any other antitoxine at present known to us.

Some Personal Experiences of the Epidemic of Enteric Fever among the Troops in South Africa, in the Orange River Colony. By Dr. H. H. Tooth.—The author discusses this outbreak of typhoid fever under the following heads: 1. The origin of the epidemic. The Bloemfontein epidemic should be regarded as the direct continuation of that begun at Modder River. 2. Dissemination of the disease. The main agencies, in the order of their relative importance, were (a) infected water-supply, (b) sand storms and dust, (c) flies, and (d) personal infection from man to man. 3. Precautions taken by the authorities to prevent the spread of infection. These include the various methods of purifying the water and of disinfecting excreta. 4. Preventive inoculation. Of 232 cases of typhoid seen by the author, 54 had been inoculated against the disease; of these, 4 died, or 7.4 per cent. Of the 178 uninoculated cases, 25 died, or 14 per cent. Of 34 officers, 21 had been inoculated, and of all these only one died, and he

had not been inoculated. The author's impression is that the disease takes a milder and more benignant course in the inoculated than in the noninoculated. 5. Treatment. Fresh milk was very difficult to obtain, and condensed milk was used in many cases, together with beef-tea, with good results. Alcohol was used very sparingly and only in the severer cases, it being replaced by digitalis and strychnine. Perforation took place in five cases; of these, two were operated on, but death took place in both, four or five hours after operation.

The Clinical and Pathological Relations of the Chronic Rheumatic and Rheumatoid Affections to Acute Infective Rheumatism. By Dr. A. E. Garrod.—The main subject for discussion in this paper is the relationship of rheumatoid arthritis to acute rheumatism. The author is inclined to the belief that they are entirely distinct and separate diseases. Rheumatism is such a common disease that a history of it is often obtained in cases of rheumatoid arthritis. Acute rheumatoid arthritis is often attended by considerable febrile disturbance, and at this stage is often mistaken for rheumatic fever. Further, rheumatic fever is followed by a chronic joint affection clinically indistinguishable from rheumatoid arthritis. Sufferers from the latter disease show no greater liability to valvular disease than others not so afflicted. The question can only be settled by pathological means, such as bacteriological examination, which, in the case of rheumatic nodules, has already yielded such interesting results in the hands of Poynton and Paine. At present the pathology of rheumatoid arthritis is unknown.

The Toxicological Detection of Arsenic and the Influence of Selenium on its Tests. By W. H. Willcox, M. B.—The author's experiments go to show that, while selenium does not give any result *per se* with the Marsh test in the absence of arsenic, yet it has a most decided effect upon the nature of the mirror when arsenic is present. The proximal half of the mirror is of a vermilion-red color, while the distal portion has the usual appearance of the arsenical mirror. The author examined many of the samples of contaminated beer from Manchester during the recent epidemic of peripheral neuritis, and in no case were the curious mirrors obtained, such as are given by selenium and arsenic combined. These facts prove that the poisoning could not have been due primarily to selenium and, secondarily, to arsenic, as has been suggested by others.

Septic Disease in Graduated Attacks in the Same Patient. By Dr. J. Snowman.—The author reports the case of a woman who had three or four distinct rigors between the third and sixth day after she was delivered of her sixth child. Three years later, she aborted after seven weeks' amenorrhœa, and the abortion was followed by a distinct attack of septic poisoning, with rigors, temperature of 105° F., and localized suppuration in the vulva and abdominal wall. Two years later the patient again aborted, and again the abortion was followed by septicæmia of a most severe type, going on to pyæmia. Abscesses formed successively in the left thigh, the right wrist, the left elbow-joint, and the left knee-joint. These were opened and drained, and the patient made a tedious but complete recovery. No antistreptococcic serum was used, the case being treated on ordinary surgical lines.

Presse médicale, February 23, 1901.

Small-pox in Paris. By M. H. Roger.

Parenchymatous Myocarditis of Rheumatic Origin.—M. Pierre Merklen and M. Rohé report their findings

in a case of parenchymatous myocarditis, in which no healthy muscular fibres existed. There was a complete atrophy with destruction of the transverse striations, granular degeneration, and tumefaction of the nuclei. Vacuolization was found in those parts of the muscle which had completely surrendered to the process. The authors believe that the toxic effects induced by the rheumatism from which the patient suffered affected the myocardium in the same way as the toxins of the other infectious diseases do.

March 6, 1901.

Struggle against Leprosy in French Indo-China. By M. E. Jeanselme.

Arthritic Œdema of the Eyelids.—M. A. Trousseau says that his study of several cases of œdema of the eyelids leads him to believe that many of these instances are due to rheumatism; and he thinks that if all such cases were carefully observed a rheumatic basis would frequently be found. The observation has an important therapeutic bearing.

Indépendance médicale, March 6, 1901.

Contusions of the Heart and Pericardium.—M. Mauclore says that these are not numerous accidents and that they are always due to severe injury to the chest. The symptoms are those of great shock, intense dyspnoea, irregular, small, and rapid pulse. Death usually follows at once, and is due to reflex inhibition of the heart's action, to its arrest by compression, or to hæmorrhage. In some cases the heart continues to beat tumultuously, the pulse becomes very rapid and small, blood collects in the pericardium or mediastinum, and death soon follows. Injury to the heart or pericardium should always be suspected when grave injuries to the right side of the chest are encountered, and the rapid evolution of the symptoms with a fatal result will make the diagnosis usually a correct one.

Progrès médical, February 23 and March 2, 1901.

Aphthous Stomatitis.—M. Gabriel Arthaud describes a scarlatiniform eruption which accompanies acute aphthous stomatitis. It may be hæmorrhagic or erythematous in character, or appear as opalescent pustules, the miliary form. It is accompanied by a high temperature with slight morning recessions. It covers the entire body or may be limited to the mouth and mucous membranes.

Sterilization of Milk and the Results of its Use. By M. Axel Johannessen. (*Continued article.*)

Propagation of Malaria by Mosquitoes. By Dr. Patrick Manson. (From the *Lancet* of September 29, 1900.)

Sterilization of Milk and the Results of its Use. By M. Axel Johannessen. (*Continued.*)

Journal des praticiens, March 2, 1901.

Pleuro-typhoid and Typhoid Pleurisies.—M. Paul Remlinger says that pleurisies which appear in the course of severe enteric disease are almost always caused by Eberth's bacillus, except those pleurisies of secondary microbial infection. A distinct morbid entity is constituted by those cases of serous pleurisy which precede a mild typhoid, a typhoid so attenuated that it gives rise only to an intestinal or gastric discomfort; this is the so-called pleuro-typhoid.

The pleurisies which appear during a typhoid fever

offer a more serious prognosis. They may be serous, purulent, or hæmorrhagic. The prognosis depends upon the purulent character of the effusion and its appearance in point of chronology. The subacute onset, the preference of the effusion to locate on the left side of the chest, and the tendency of the fluid to become sterile by the disappearance of Eberth's bacillus, are characteristics of this form of pleurisy.

Poisoning by an Aniline Dye. By M. Laurent and M. Guillemin.

Orbital Heteroplasty. By M. Felix Lagrange.

Lyon médical, March 3, 1901.

Congenital Malformation of the Œsophagus.—M. E. Weill and M. Péhu report an autopsy on an infant that had shown from birth the signs of an imperforate Œsophagus. Ingestion of milk was always marked by great dyspnoea and cyanosis and the fluid was ejected about fifteen minutes after it had been taken. Radioscopy showed a diverticulum at the right of the sternum. At the autopsy, the Œsophagus was seen to exist in two parts; the superior terminating in a *cul-de-sac* just below the bifurcation of the trachea, the inferior portion passing on to the stomach. There was no other visceral anomaly of development. The child died of bronchopneumonia. The authors regard such cases as hopeless from a therapeutic point of view, as surgical measures are almost certain to end fatally, while rectal feeding is unsatisfactory, although it should be tried.

Multiple Tuberculous Strictures of the Small Intestine.—M. Maurice Patel, in this instalment, records the symptoms and treatment. Constipation is the rule, although there may be diarrhoea which is continuous. Colic is frequent, usually coming on two or three hours after eating, the abdomen becomes tympanitic at one place, soon to be followed by the appearance of tympanites at another place, when the pain shifts its location. Musical murmurs may sometimes be heard even at a distance from the patient. Meteorism, the sensation of a definite mass in the abdomen, the great mobility of the small intestine, the detection of mesenteric masses, are important diagnostic signs. Stercoral fistulæ or even intestinal perforations may occur. Surgical measures offer the only form of treatment, some form of intestinal anastomosis being necessary.

Gazette hebdomadaire de médecine et de chirurgie, February 28, 1901.

Hysterical Tympany. M. P. Londe and M. R. Monod report the case of a single woman, thirty-three years of age, who presented enormous distention of the abdomen. She was hysterical and was eventually cured. Before coming under the observation of the reporters, she had been twice laparotomized, each time complaining of intense pain under the left false ribs. No organic disease could be discovered.

March 3, 1901.

Infection of Wounds by Perspiration of the Hands.—M. E. Genevet has adopted this method of sterilizing his hands for surgical procedures: Washing and scrubbing with soap and water for fifteen minutes, then washing with a pad of sterilized gauze impregnated with ether, then rinsing them with ninety-five per cent. alcohol, and finally washing them with sterilized water for five minutes. No cultures could be obtained from the hands after this method of disinfection. But when the

hands were made to perspire freely after such a washing, the transpired fluid always yielded a pure and virulent culture of the *Staphylococcus albus*. The author concludes: (1) that it is possible to obtain absolute sterilization of the hands; (2) that as soon as perspiration of the hands begins, infection of the wound is possible; (3) that, as it is impossible to disinfect the operative area, the lips of the cutaneous wound should always be protected; (4) disinfection of the hands should be completed by their immersion for ten minutes in a two-per-cent. solution of tannin to inhibit the sweating; (5) gloves should be worn in septic operations where mere manual dexterity is not an important factor.

Centralblatt für Gynäkologie, March 2, 1901.

Preliminary Bath of Parturient Women as a Source of Infection.—Dr. Sticher says that his experimental studies have convinced him, as they have Professor Stroganoff, clinically (see *New York Medical Journal*, March 16, 1901), of the danger of introducing pathogenic bacteria into the bath into which a parturient woman is placed. He introduced into such a bath the *Bacillus prodigiosus*, which is not ordinarily found in the vaginal secretion, and was afterward able to secure these organisms from the vagina of a woman who had bathed in the water.

A New Operating Table. By Dr. P. A. Fenger Just and Dr. A. Madsen.

Wiener klinische Rundschau, February 24, 1901.

Massage in Lymphangitis.—Dr. Batsch recommends massage in early cases of lymphangitis, lymphadenitis and phlegmons. By this means leucocytes are attracted in greater numbers to the field of infection and thus exert a more powerful phagocytic action than is otherwise possible. While this is purely theoretical, the author says he will continue to use it, although his first case, *in corpore vili*, was not entirely successful.

So-called Sclerotic Hemisphere Atrophy. By Dr. Ernst Bischoff. (*Continued article.*)

Vegetarianism. By Dr. W. Thurn. (*Conclusion.*)

Wiener klinische Wochenschrift, February 21, 1901.

Phosphorated Oil. By Dr. Konrad Stich.

Gastric Carcinoma Following Ulcer of the Stomach.—Dr. Anton Krokiewicz reports the case of a man of thirty-four years of age who developed a carcinoma of the stomach at the site of a former ulcer, who died after a very rapid course of a few weeks only.

Casuistics of Intestinal Lipoma. By Dr. Ernst Füchsig.

February 28, 1901.

Cinnamic Acid Treatment of Tuberculosis.—Dr. Julius Pollak reports the clinical results in a number of cases of tuberculosis treated at the sanatorium in Alland by cinnamic acid. In many of the cases the injection of the acid exerted an antipyretic influence, but in two of them the treatment had to be discontinued on account of an increase in temperature. Expectoration was rendered easier. The remedy seemed to be harmless, as no sequelæ were observed from its use, nor did a hæmoptysis ever directly follow an injection. In selected cases, the author thinks that cinnamic acid is of real value; but it cannot replace regular sanatorium treatment.

Intravenous Injections of Cinnamic Acid in Tuberculosis.—Dr. C. Hödlmoser reports encouragingly and

thinks that this method of treatment should be widely employed before its rejection.

Rare Intestinal Injuries. By Dr. V. Subbotié.

Centralblatt für Chirurgie, March 2, 1901.

Medullary Narcosis.—Dr. Karl Schwarz has tried eucaïne β as the anæsthetic agent and found it unsatisfactory. He has also tried to avoid the disagreeable effects of cocaine by making use of Racoviceanu-Pitesci's suggestion of injecting cocaine into the subarachnoid space the day before the attempted operation. In this instance the effect of the cocaine was marked by the usual disagreeable symptoms. With the use of tropococaine, however, no pallor or sweating, nausea, vomiting, headache or vertigo have been observed, while anæsthesia was complete. The author has performed Whitehead's operation for hæmorrhoids, and also herniotomies under this method of anæsthesia, with perfect satisfaction. Seven tenths of a grain of tropococaine is sufficient to produce anæsthesia.

Pseudo-arthritis of the Terminal Digital Phalanx. By Professor W. Müller.

March 9, 1901.

Treatment of Severe Scoliosis.—Dr. Peter Bade describes an apparatus which is applied in such a way that, after forcible reduction has been practised, increased pressure may be brought upon the scoliotic area as the wearer of the plaster jacket grows.

New Suturing Method for the Recti in Ventral Herniæ.—Dr. A. Hammesfahr, in a case of median ventral hernia, separated the recti muscles with their sheaths anteriorly and posteriorly from the symphysis to the ensiform cartilage. This was done without opening the peritoneal cavity. A suture of wire was then passed from the aponeurosis of the external oblique into the middle of the rectus muscle and out through the other side in a similar manner. This was done through the entire length of the muscle, so that its inner surfaces were slightly inverted when the sutures were tightened. An excellent result followed the operation.

Riforma medica, February 2 and 4, 1901.

Concerning the Regeneration of the Suprarenal Capsules. By Dr. G. B. Ramoino.—The author has observed the process of regeneration in suprarenal capsules after various operations which involved the destruction of a portion of the gland, and sums up his observations in the following statements: After wounds, contusions, or the application of caustics to the suprarenal tissue, the gland heals by cicatrization, preceded by more or less severe inflammatory reaction, which begins with an extravasation of blood, and includes the formation of a more or less circumscribed area of gangrene. The extravasations are more marked in capsules which had been mutilated by removing a segment with a knife than in those in which the injury had been a contusion or a destruction by means of caustics. The necrosis of the capsular parenchyma is less marked in incised wounds than in contusions or in burns with caustics. The proliferation of small cells is more abundant in the capsules subjected to the two last-named procedures than in capsules which have been simply cut with a knife. When a wound extends into the cortical substance, the hæmorrhage is more abundant and the clot persists for a longer time than in wounds involving the cortex only. Perhaps the reason of this is that, in the former, the inflammatory reaction is more intense. The proliferation of

parenchyma cells after an injury to the suprarenal is so abundant that a true regeneration of the tissue of the gland takes place.

February 5, 6, 7, and 8, 1901.

Relapsing Neuropathic Lymphangitis. By Dr. Sante Solieri.

Two Cases of Primary Sarcoma of the Liver. By Dr. Bindo De Vecchi and Dr. Guido Guerrini.—The authors report the autopsies and microscopic findings in three cases of sarcoma of the liver. From a study of these cases, and from a critical review of the literature of the subject, they conclude as follows concerning the histogenesis of primary sarcoma of the liver: The tumor primarily develops from cirrhotic lesions that precede its formation in the liver. A succession of sarcomatous nodes develops in the connective tissue at the periphery of the tumor and within the bands of connective tissue that surround it. The second stage of the growth of the tumor consists in the enlargement of the nodes until they coalesce into a continuous mass of sarcomatous tissue.

February 9, 11, 12, and 13, 1901.

Experimental Researches Concerning the Use of Antitoxic Serum in Tetanus. By Dr. Guido Tizzoni.—The author gives an account of the efficiency of the serum which he has prepared for the treatment of tetanus, and reports a large number of experiments on animals which he cites as proofs of his assertions. He concludes that his serum has a very distinct curative effect if administered in sufficient doses and early enough. A second paper will be devoted to a comparative study of Tizzoni's serum and the serums against tetanus prepared by other observers.

Vratch, February 3, 1901 (February 15, New Style).

Hydrorrhœa Nasalis. Report of a Case. By Dr. A. F. Eckert.—The author had a case of this rare and comparatively obscure disease under his observation for a year. The patient was an unmarried woman aged thirty-nine years. In October, 1899, she began to feel feverish at times, and with this there appeared a peculiar tickling sensation in the nose, accompanied by a discharge of watery fluid from the nostrils. She also began to complain of pain in the chest, and a persistent cough appeared. The patient had been suffering from chronic catarrhal inflammation of the nasal mucosa for a number of years, but had been treated for this trouble with good results. On examination, the lungs showed dulness at the left apex and râles over the left lung. There were elevations of temperature which came on rather suddenly, usually at about five o'clock in the morning, and were accompanied by chills and prostration, and sometimes followed by sweating. Before such an attack the flow from the nose increased, during the attack it decreased. There never was a tendency to sneeze. No malarial parasites were found in the blood. The discharge amounted to 120 grammes in twenty-four hours, and, as a rule, flowed from the left nostril only. If the head was held bowed down, the stream became continuous and kept on flowing until she raised her head again. It was supposed that the fever was due to the presence of bronchiectases which were too small or too deeply situated to give physical signs. The lacrymal apparatus was found normal, so that the secretion could not be attributed to a disorder of this function. The nasal mucous membrane presented no deviations from the normal. A removal to a southern climate (Crimea) improved the

fever, the cough, and the nasal discharge considerably, but her return to the north was followed by an exacerbation of the symptoms. The patient was gaining in weight during this period. All manner of local and general treatment was tried without avail. (*To be continued.*)

The Spleen and the Trypsin Ferment of the Pancreas. By Dr. L. B. Popelsky.—(A reply to Dr. A. A. Gertzen. See abstract in the *New York Medical Journal* for March 2, 1901, p. 387.) The question under dispute is: Has the spleen any influence upon the formation of the trypsin ferment of the pancreatic juice? The present author strongly champions the negative side and devotes a lengthy article to arguments in support of his view and to broadsides against his antagonist, Gertzen.

Difficulties Met with in the Combat with Diphtheria. By Dr. E. M. Wolfson.—The author has had occasion to observe certain cases of diphtheria in houses from which patients with that disease had been removed to a hospital, and which had been thoroughly disinfected. He recommends that all forms of mild amygdalitis should be examined bacteriologically. In addition to the use of antitoxine, local treatment should be employed in order to hasten the disappearance of the bacilli. Patients should not be discharged from the hospital without repeated bacteriological examinations. If, for some reason, the patient is discharged with bacilli still in his throat, the attending physician or the health authorities should be notified. If true diphtheria bacilli persist for a long time in the throat of an individual, the virulence of these germs must be tested by inoculation into animals. Isolation should be continued for from four to six weeks, and, at the close of this period, the throat and nose should be irrigated several times daily with antiseptic solutions. Schools in which cases of diphtheria occur and in which it is impossible to make a bacteriological investigation in every scholar, should be closed for three or four weeks.

Corporal Punishment in Russia in the Twentieth Century. By Dr. D. N. Jbankoff (*concluded*).—The author concludes that corporal punishment is by no means abolished in Russia at the present date, and that it cannot be abolished without legislative interference. He urges the medical profession, as well as society in general, to continue to cry out against this shameful practice which reflects injuriously upon the whole Russian nation.

Concerning the Use of Injections of Sodium Cinnamate in Tuberculosis. By Dr. L. A. Finkelstein (*concluded*).—The author concludes this article by saying that he cannot speak of any positive success; but cinnamate of sodium did not do any harm. This remedy cannot compete with the ordinary hygienic and dietetic measures against tuberculosis.

Roussky, Archiv Patologii, Klinitcheskoy Meditsiny, i Bacteriologii, December, 1900. (Russian Archives of Pathology, Clinical Medicine, and Bacteriology.)

A Contribution to the Subject of Intestinal Self-intoxication. Concerning the Changes in the Liver in Obstruction of the Intestines. By Dr. A. M. Levin.—The author describes the changes which he has observed in the liver in cases of intestinal obstruction, as follows: A marked hyperæmia as the result of vasomotor changes, sometimes hæmorrhages; degenerative changes in, and atrophy of, the liver cells, in which the nuclei do not take part, and which, in all probability, may return to

normal; evidences of inflammation in the stroma of the organ and desquamation of the lining of the biliary canals. The least important of these changes is undoubtedly the degeneration of the cellular protoplasm. Vacuolization of liver cells is found even in normal animals, and seems to depend on the stage of digestion in which the animal is killed, as well as on the quantity and quality of the food consumed. The changes due to vasomotor alterations, especially the compression atrophy, are more important. These processes are capable of causing, in the course of time, a deficiency of the liver functions as a result of chronic self-intoxication. The question whether, in addition to the absorption of poisonous substances from the intestines in cases of obstruction, there is also a migration of intestinal germs into the blood, and whether such emigrated germs may produce lesions in the liver under these conditions, remains to be settled by further researches.

Concerning the Question as to the Pathogenesis of Diplobacillar Conjunctivitis and the Biology of the Diplobacillus of Morax-Axenfeld. By Dr. F. F. Rymovitch.—In 1896, Morax described a germ which he found in the secretions of patients affected with subacute conjunctivitis accompanied by mild objective symptoms. Soon afterward Axenfeld found an identical germ in the same class of cases. Pure cultures were inoculated into conjunctivæ and the appearances of conjunctivitis of the subacute type followed within four days, the secretion of these patients containing the same germ in pure culture. Since then, this diplobacillus has been found in subacute conjunctivitis by a number of other observers. The author has investigated bacteriologically 116 cases of conjunctivitis. Of these, thirty-three, or 28.4 per cent., showed the presence of the diplobacillus discovered by Morax and Axenfeld. If the cases of acute and eczematous conjunctivitis are deducted from the total, 52 per cent. of all the others were caused by the aforesaid germ. This micro-organism occurs as a double bacillus with a distinct line of division between the two members. Each member is about 2 micromillimetres in length, and the length of the whole organism is 5 micromillimetres, while its width is from 0.50 to 0.75 micromillimetres. The ends are well rounded. The germs are often seen in chains of three or four, and occur in abundance in the secretion. They are easily stained with aniline dyes and are completely decolorized by Gram's solution. They are easily distinguished from pneumococci by the absence of a capsule. They grow with difficulty on ordinary media, but cultures may be easily obtained on media containing human serum or blood, and also on agar mixed with nutrose, as well as on agar with pigeon's blood. The clinical features of the conjunctivitis that they cause are those of ordinary subacute and chronic catarrhal conjunctivitis. In four cases the inflammation was intensely acute, probably because the germs were more virulent than usual. In some cases of acute conjunctivitis the author found, in addition to the bacillus of Koch-Weeks, a few diplobacilli. The majority of cases of the diplobacillar type occurred during the summer months. Zinc sulphate acts as a specific in these cases, but silver nitrate, in ten times weaker solutions, also gives good results, although its effect is not so constant as that of the zinc salt.

Studies on Phagocytosis in Fatal Infections. By Dr. Th. Tchistovitch.—The author has studied the process of phagocytosis in the organs of animals that had died of infectious diseases. He examined the organs of ten rabbits that had been inoculated with extremely viru-

lent cultures of streptococci, and had been killed at various intervals in the process of infection. He found that there was always a polynuclear phagocytosis in the lungs. On the other hand, in the liver, some of the streptococci were engulfed by the cells of Kupffer, while others remained free. There was no polynuclear phagocytosis in the spleen, the marrow, or the kidneys. To sum up, a general infection of the fatal type is marked by absence of leucocytic phagocytosis.

Concerning the Preservation of Microscopic Specimens of Urinary Sediments. By Dr. B. Koslovski.—The following method is recommended by the author: He places a cubic centimetre of an aqueous solution of any aniline dye, such as one-per-cent. eosin, into the tube of a centrifuge, and adds the urine to be examined. After having centrifugated this mixture he obtains a beautifully stained sediment. If a scanty sediment results, the first amount of urine is decanted and another portion is added, the mixture being again centrifugated, etc., until enough sediment is obtained. The urine is then decanted completely. A little of the sediment is now taken with a pipette or with a platinum loop, and placed on a slide on which a drop of Farrant's mounting fluid had previously been poured. This fluid is prepared as follows: Equal parts of distilled water, glycerin, and a saturated solution (in boiling water) of arsenious acid. Mix, and add gum arabic in pieces until half of the fluid is displaced. Allow to stand three weeks, stirring daily with a glass rod until all the gum is dissolved. The liquid may then be filtered, but this is not necessary. The specimens thus prepared may be kept for years without any change in the appearance of the sediment.

Researches Concerning the Physiology of Phosphorescent Germs. By Dr. L. Tchougæeff.

Proceedings of Societies.

NEW YORK OBSTETRICAL SOCIETY.

Meeting of February 13, 1901.

The President, Dr. H. J. BOLDT, in the Chair.

Persistent Amenorrhœa.—The PRESIDENT mentioned a case of defective menstruation dating back to the time of the first menstruation, at the age of thirteen. Before her marriage the patient menstruated at intervals of three or four months; since that time (three years) she had menstruated only twice. The pelvic organs were normal, with the exception that the uterus was slightly smaller than it should be.

Dr. H. N. VINEBERG remarked that in some cases after marriage small uteri seemed to diminish in size and lost their function rather than developing, as one might expect.

Cæsarean Section for Fibrocystic Uterine Tumor.—Dr. GEORGE L. BRODHEAD reported a case. The specimen presented was one of fibrocystic growth of the uterus removed from a patient upon whom Cæsarean section had been performed eleven days before. The woman first came under his observation on November 20, 1900, when she presented herself for examination in the lying-in service of the New York Post-graduate Hospital. She was thirty-four years of age, had been married two years and a half, and her menstrual history prior to marriage and up to the time of the present pregnancy had been normal in every respect. There had been no symp-

toms at any time of uterine growth, and her general condition was very good. The last menstruation had begun on May 6th, and had continued for three days, the usual amount of blood having been lost. Abdominal examination showed a uterus enlarged to the size of about seven months' gestation, the fundus being higher than it should have been to correspond to the period of pregnancy as based upon the date of the last menstruation, namely, six months, or a little over. The presentation was of the vertex, the head being high above the brim, and the position the left occipito-anterior. The foetal heart rate was 148, and a loud uterine souffle was heard in the right upper quadrant. The pelvis was of the justo minor type, the woman being of small stature, about five feet two inches in height, and weighing about 109 pounds. Vaginal examination revealed a tumor of the size of an orange, of moderately firm consistence, well down in the cul-de-sac of Douglas, pressing the cervix well forward behind the symphysis. With the idea that the tumor might be one of the ovary, or a pediculated fibroid, which might be made to slip back into the abdominal cavity, the patient was placed in the knee-chest posture, but the growth was so adherent that it could not be replaced. The patient was extremely anxious to have a living child, and therefore Cæsarean section at or near full term seemed indicated. Dr. Dudley concurred both in the diagnosis of fibrocystic growth and in the advisability of performing Cæsarean section. On January 19th the position was found to be left sacro-anterior, the breech being well above the brim, and a loud umbilical souffle was heard in the left lower quadrant of the uterus. On February 2d the operation was performed at the New York Post-graduate Hospital, the patient being within ten days of full term. It seemed best to elect this time for the reason that the child was of good size and the uterus already well distended. In the operation, able assistance was rendered by Dr. Dudley and the house staff of the hospital, Dr. Boldt and Dr. Ward being present also. The technique of the section was that described by Dr. Dudley in the *New York Medical Journal* for November 3, 1900, in his article, *The Modern Cæsarean Section—An Ideal Method of Treatment for Placenta Prævia*. Under constant irrigation with a hot normal saline solution, an incision six inches in length was made in the median line from a point just below the navel to just above the symphysis, and the uterus exposed. A rubber ligature was then passed over the fundus and carried down to the lower segment of the uterus, just above the fibroid. While the uterus was held up and the ligature tightened by an assistant sitting between the legs of the patient, and while the abdominal walls were kept closely applied to the uterus above, an incision about six inches in length was quickly made through the uterine wall, and the foetal sac opened. The breech of the child, found lying just beneath the incision, was seized, the child lifted out, and the cord clamped and cut. The amount of amniotic fluid was small. The uterus was followed down and lifted out of the abdominal cavity, while the intestines were protected above. The child, a male, weighing six pounds seven ounces, was extracted five minutes after the operation was begun, in good condition, and soon cried lustily. The placenta was found lying loose in the uterine cavity, and was removed, with its membranes, manually. The tumor was adherent to the rectum, but the adhesions were soon separated and the growth was lifted up out of the abdominal cavity. It was then found that during its removal the cyst had

ruptured, allowing a small quantity of yellowish-brown fluid to escape. The mass was of about the size of an orange, and was attached to the posterior wall of the uterus by a thin pedicle about an inch and a half in width. The growth was enucleated and the uterine wall closed with several layers of fine catgut sutures. Ten minutes had been occupied in the removal of the fibroid. A finger was then passed through the cervix from the uterine side, and the incision closed in layers with a continuous suture of fine No. 1 ten-day chromicized catgut. Beginning above, the mucosa was first closed, then, from below upward, the muscular layer and finally the peritoneal coat were united. The ligature was now loosened, and several sutures were passed to control slight oozing. As there was a moderate amount of bleeding from torn adhesions, a strip of iodoform gauze was placed in the cul-de-sac and the end drawn out of the vagina. The incision in the abdomen was closed in layers with catgut, and the patient put to bed in excellent condition, a little less than an hour having been consumed in the entire operation, and the loss of blood having been very small. The child was well developed, and since birth had done well. The mother's recovery had been uninterrupted from the first.

Dr. VINEBERG asked if it would not have been feasible to remove the growth *per vaginam*.

Dr. BRODHEAD stated that the patient was a primipara thirty-five years of age, exceedingly anxious to have a living child, and perfectly willing to undergo the operation at full term. Under these circumstances it seemed best to wait, as an operation *per vaginam* would almost certainly have induced premature labor, with the probable loss of the child.

Tuberculous Peritonitis.—Dr. E. H. GRANDIN presented the uterus and appendages. For three months the abdomen had been enlarging, and a diagnosis had been made of tuberculous peritonitis. On abdominal section, the parietal peritonæum was found enormously thickened, fully an inch thick. About a gallon of fluid was evacuated. Every organ in the pelvis and abdomen was covered with tubercles. The appendages were adherent and the tubes contained thin pus. The hysterectomy was difficult. The abdomen was washed out with normal saline solution and gauze was carried into the vagina. Strange to say, the woman was still draining six weeks after the operation, by the vagina, but she had gained rapidly in flesh and in appearance.

Dr. W. S. STONE asked if the disease was primary in the tubes.

Dr. GRANDIN replied that he could not say. His reason for removing the uterus and appendages was that better drainage could be secured. The results had justified the course pursued.

The PRESIDENT added that drainage in cases of tuberculous peritonitis was the proper after-treatment, and Nature seemed to be providing the treatment in the case reported.

An Unruptured Ovum from an Ectopic Pregnancy was presented by Dr. B. H. WELLS. The patient was a Russian woman, twenty-six years of age, with no history of abnormalities in either her labor or convalescence. Her menstrual history had been normal. Ten weeks before the time of operation she menstruated for the last time. Skipping the next period, she was supposed to be pregnant. Six weeks later she began to have a moderate amount of pain in the left side; it was not severe. On January 28th, the day of the operation, she had had severe cramps during the night and felt faint. She went

to the clinic, and the physician said she simply had colic. Five minutes later her pulse was found to be 140, and there were signs of internal hæmorrhage. The diagnosis of ruptured ectopic gestation sac was made. She was admitted into the Polyelinic Hospital at 10 p. m. in a desperate condition. Her abdomen was opened, she was given hypodermics of strychnine and hot salines, and her condition became somewhat better. Five or six ounces of dark blood clots were found, which were probably from the hæmorrhage of the day before, and the abdomen was filled with recent blood. The tube was fairly low down in the cul-de-sac, and sticking out was found this ovum. It was the fimbriated extremity which was still bleeding. During the manipulation the ovum dropped out of the tube. The patient was filled with hot salines, the abdomen was washed out, and she was well to-day.

Acute Bacteriæmia.—The PRESIDENT narrated the case of a patient who had a criminal abortion produced by a midwife on January 16th. Two days later she was attacked with fever. The physician who was called did a thorough curetting, removing some placental *débris*. After the curetting the uterus was swabbed with carbolic acid. The temperature, which had been 104° F., dropped to 100° F., but four days later it again reached 104° F., and from that time on it varied between 102.5° and 104.5° F., being usually above 103° F. She was seen in consultation late at night on January 25th. The pulse was 130 and the temperature 103.6° F. There was no sensitiveness on external examination, except over the uterus. The heart and lungs were normal. Bimanual examination showed the uterus somewhat increased in size and sensitive, and the condition of the external os did not indicate the presence of foreign material within the uterus. The parametria were free. A blood culture was made the same night, although there had been no chills at any time. The examination of the blood specimen on the following morning showed a negative result. Another specimen was then taken from the median vein. At noon no positive result had yet been obtained, but it was evident that the patient was rapidly getting worse, and the source of the infection being apparently the uterus alone, the secretions from the interior of which showed streptococci and *Staphylococcus aureus*. Vaginal hysterectomy was decided upon and performed with the use of clamps. The time occupied was four minutes. The patient continued to sink, and died about thirty hours after the operation. A blood culture made soon after death showed mixed infection. Sections through the uterus from the site of the placental attachment showed the structures to be invaded quite deeply with streptococci and staphylococci. He believed that an earlier operation might have saved the patient's life.

Vaginal Hysterectomy by Morcellation for Fibroids.

—The PRESIDENT also reported this case. The patient from whom the specimen had been removed was forty-three years old, and had been suffering from atypical hæmorrhages for two years, besides numerous pressure symptoms from the tumor, which completely filled the pelvis. Morcellation and bisection of the uterus made the operation comparatively easy of performance. Only four ligatures were required to complete the work, during which but little blood was lost.

Dr. GRANDIN rather protested against the term bacteriæmia. At the present time we were inclined to look upon germs as the causative element in these conditions, but we might not do so in the future. He still liked the

terms *sapræmia* and *septicæmia*. Oftentimes we dared not operate early enough, and in many cases the uterus was removed unnecessarily.

Dr. VINEBERG stated that he had operated upon a patient about a year ago for puerperal sepsis, and that the uterus had shown almost the same change as the one the president had presented. The patient recovered. A blood examination at the present time was not satisfactory; while we were waiting for the blood examination the patient was getting beyond hope.

The PRESIDENT said that at the time of operating he had thought the infection was local, with intense constitutional symptoms, and therefore that removal of the uterus was justifiable. The parametria were free, and there were no complications in the pelvic organs. The specimen showed how apt we were to err, and it should stimulate us to try to get on the right track.

Notes Relating to Cases of Ectopic Gestation.—Dr. GRANDIN gave a talk on this subject, relating the clinical histories of many cases seen both in his own and in consultation practice. His experience had taught him that many of the patients with whom he had had to deal gave histories which were decidedly atypical, judging by the classic symptoms spoken of in the majority of the text-books. He believed that, when we were in doubt, it was advisable to make a posterior incision into the cul-de-sac, for the purpose of establishing the diagnosis. Abdominal section could then be resorted to for the removal of the mass, if the posterior section was insufficient for the purpose.

Dr. GEORGE T. HARRISON thought the reader of the paper should have made a clearer distinction between cases in which the ovum was dead and those in which it was living. In the latter class of cases the extreme softness of the tumor lying near the uterus was a very characteristic symptom. Again, when the ovum was dead, the uterus was hard, whereas, if the ovum was living, the uterus was usually soft. He believed all cases of ectopic gestation should be attacked through the abdominal wall, and not by a posterior colpotomy. He thought that the rupture of the tube was a rare termination, while tubal abortion was a frequent termination. At least eighty per cent. terminated in that way. After the death of the ovum the picture changed, and the tumor became harder. He strongly advocated abdominal section for such cases.

Dr. J. E. JANVRIN said that as far back as in 1886 he had strongly advised abdominal section for all cases of supposed tubal or abdominal gestation. As a rule, we did see some, generally many, of the symptoms which were ordinarily laid down in our text-books for guidance. There was usually the lapse of one menstrual flow, followed by irregular bleeding, colicky pains, severe shock accompanying the pains, and other symptoms leading us to suspect pregnancy. He could see no reason for approaching such cases in any other way than by abdominal section, and believed that the preliminary expulsion through the vaginal wall was entirely unnecessary.

Dr. VINEBERG thought that in certain cases the incision into the cul-de-sac for the purpose of diagnosis was a valuable one. In one instance he had in that way removed a cystic ovary in a case of suspected ectopic pregnancy. He believed that Dr. Mann had reported a case in which he lost the patient by making an incision into the cul-de-sac. The patient bled so profusely that before he could find and catch the bleeding vessel she died.

Dr. CLEMENT CLEVELAND said he also was of the opinion that abdominal section was much better in every way than posterior colpotomy. His experience was the same as that of Dr. Grandin, that in a large majority of the cases but few of the positive diagnostic symptoms were present. He was positively opposed to opening the posterior cul-de-sac for the removal of a tubal gestation ovum, for the reason that the danger of hæmorrhage was too great, and therefore the procedure too hazardous. During the past three weeks he had seen three cases of ectopic pregnancy, all of which had presented features of interest. In the first, the sigmoid flexure presented under the incision, and it was found difficult to penetrate beneath the intestine, which completely hid the uterus and pelvic contents. Finally he succeeded in effecting an entrance, but in so doing tore up a flap of the serous and mucous coats of the sigmoid for at least an inch and a quarter. This was at once repaired. The right tube was removed with its contents, and as a precaution, on account of the injury to the intestines, he put in a gauze drain. The patient did well for several days; then, upon his drawing down the gauze, fæcal matter appeared. The symptoms became severe, and he performed vaginal hysterectomy as the only means of saving her life. The fistula was now closing rapidly. In the second case the right tube was removed by posterior section, and the bleeding was so great from the whole surface of the cavity where the mass had been lying that it was necessary to pack the cavity. Bleeding continued, and it required very thorough tamponing to arrest the hæmorrhage. After this the patient did well, but the case emphasized the point that the lower route was not a safe one through which to remove a tubal gestation ovum. In the third case the patient had been curetted twice under the supposition that the case was one of incomplete abortion. The speaker diagnosed the condition as that of ectopic pregnancy, and, on operating, found an unruptured tubal gestation sac of three and a half to four months. In removing the tube he had used Skene's electric clamp, for he preferred it because of the liability of ligatures to cut through the soft tissues. The patient recovered.

Dr. A. BROTHERS said that the frequency of ectopic gestation was to him alarming. He had had a case some weeks before in which the mass was so bound down by adhesions that it was necessary to remove the uterus. The patient had made a good recovery.

Book Notices.

Twentieth Century Practice. An International Encyclopædia of Modern Medical Science. By Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M. D. In Twenty Volumes. Volume XX. Tuberculosis, Yellow Fever, and Miscellaneous. General Index. Pp. vii-906. New York: William Wood & Company, 1900.

THIS, the final volume in the series, contains chapters on the bacteriology, pathology, ætiology, symptomatology, diagnosis, prognosis, prophylaxis, and treatment of tuberculosis; on yellow fever; on poisoning with snake venom; on mushroom poisoning; on diseases of the uvula and soft palate; and on the neural and mental defects in childhood. In addition, the volume contains a copious index to the subjects treated of in the various volumes.

The editor is to be congratulated upon the completion of this extensive work, and on the good judgment he has displayed in the selection of his contributors. The labor must have been great, but the result justifies the effort.

Rudiments of Modern Medical Electricity. Arranged in the Form of Questions and Answers. Prepared Especially for Students of Medicine. By S. H. MONELL, M. D., Professor of Static Electricity in the International Correspondence Schools, etc. Pp. 5 to 165. New York: Edward R. Pelton, 1900. [Price, \$1.]

DR. MONELL has presented in this volume the elementary facts in regard to electricity, its derivation, its therapeutical uses, and the physiological effects of the various kinds of current. We do not doubt that for the beginner, especially for the student, the book contains much that will be useful and instructive.

Diseases of the Nervous System. A Text-book for Students and Practitioners of Medicine. By H. OPPENHEIM, M. D., Professor at the University of Berlin. Authorized Translation by EDWARD E. MAYER, A. M., M. D., of Pittsburgh. First American from the Second Revised and Enlarged German Edition. With Two Hundred and Ninety-three Illustrations. Pp. 5 to 899. Philadelphia and London: J. B. Lippincott Company, 1900.

No book is more worthy of translation than this masterly production of Oppenheim's. Coming from a man who to-day occupies the first rank among neurologists, it reflects on every page the wide experience of the author and shows the utmost care in its preparation. Without exceeding the limits of a text-book, it covers the whole field of neurology. It is full, concise, accurate, and in entire accord with the most advanced teachings. It is with great pleasure that we take this opportunity of calling to it, in its English dress, the attention of students and practitioners in America.

Ulcer of the Stomach and Duodenum, and its Consequences. By SAMUEL FENWICK, M. D., F. R. C. P., Consulting Physician to the London Hospital, and W. SOLTAU FENWICK, M. D. Lond., M. R. C. P., Senior Physician to the London Temperance Hospital, etc. Pp. xiv-392. Philadelphia: P. Blakiston's Son & Co., 1900. [Price, \$3.50.]

THIS work is one of those masterly monographs that are far too rare in medical literature. None can read what is herein set down without great profit and a far more complete understanding of all that concerns gastric and duodenal ulcerations, for the book is very exhaustive.

So far as description goes, we can do no better than cite the preface to the effect that the work is divided into four parts, the first of which deals with the pathology and ætiology of gastric and duodenal ulcer, while the three others are devoted to a consideration of the clinical aspects of the disease and its sequelæ. The studies of the morbid anatomy of these diseases are based upon the records of 1,015 *post-mortems* in cases of ulcer of the stomach and 130 in cases of duodenal ulcer. The second part treats of symptomatology, and is based upon the clinical notes taken in 143 cases of acute ulceration, and the third part is similarly descriptive of the chronic ulcer, being based upon a study of 308 cases. The final part is descriptive of the sequelæ

of ulcerations. From the wealth of material studied and the well-known ability of the writer, it might be expected that the work would be of unusual merit, and this is indeed the case. Great value, too, is added by a number of most excellent illustrations, chiefly photographs of museum specimens.

On Diabetes Mellitus and Glycosuria. By EMIL KLEEN, Ph. D., M. D. Pp. vii-9 to 313. Philadelphia: P. Blakiston's Son & Co., 1900. [Price, \$2.50.]

THIS highly interesting and valuable monograph opens with a chapter upon definitions, and also briefly presents the historical data that concern the disease. The geographical distribution of diabetes is the subject of the second chapter, and Chapter III treats of glycosuria in its several forms. This chapter is most complete and instructive, and, in our opinion, is the most important of the work. The fourth chapter describes the symptoms and the complications of diabetes, and the fifth is on diabetes infantilis. Diabetes mellitus after removal of the pancreas is the subject of the sixth chapter, and the methods of investigating the disorder are described in the eighth. The final chapter is upon therapeutics.

There are several works upon diabetes and glycosuria that are entitled to be considered authoritative, notably von Noorden's and Naunyn's, but even by comparison with these the work before us will scarcely suffer. It is true that it is conventional in great part, for up to the present time, unfortunately, glycosuric disorders have failed to permit of much originality. The questions involved are handled in a masterly fashion, however, as might be expected of one so much in earnest as Dr. Kleen, and one, too, who has had the unequalled opportunity for the study and observation of the disease that Carlsbad affords.

The book is one that will be read with profit, and from our own reading of it we have derived an exceedingly orderly and satisfactory picture of the disorders of which it treats.

The Present Position of the Treatment of Simple Fractures of the Limbs. An Address delivered in opening a Discussion at the Meeting of the British Medical Association held in Ipswich, August, 1900. By WILLIAM H. BENNETT, F. R. C. S., Senior Surgeon to St. George's Hospital, London, etc. To which is Appended a Summary of the Opinions and Practice of about 300 Surgeons. Pp. 41. New York and Bombay: Longmans, Green & Company, 1900.

THIS volume presents the substance of the address mentioned on the title-page. In it we find not only the views of the writer on the proper methods of treating fractures in general, but also a summary of the opinions of a number of other practitioners. The author shows a partiality for the ambulatory treatment of fractures and favors the use of massage and early movement in recent cases; he, however, does not suggest their general adoption, but restricts their use to the hands of those who have had large experience in fractures.

On the Use of Massage and Early Passive Movements in Recent Fractures and other Common Surgical Injuries, and the Treatment of Internal Derangements of the Knee-joint. Three Clinical Lectures delivered at St. George's Hospital. By WILLIAM H. BENNETT, F. R. C. S., Senior Surgeon to St. George's Hospital, London, etc. With Twelve Illustrations.

Pp. x-97. New York and Bombay: Longmans, Green, & Company, 1900.

THIS little book represents, with a few additions, three lectures which have appeared in the *Lancet*. Lectures I and II are devoted to the use of massage and early movements in recent fractures and other common injuries, and Lecture III treats of the internal derangements of the knee-joint. The book concludes with an appendix on the use of massage in the treatment of recent fractures. Both this small work and its companion on the treatment of simple fractures will be found most interesting and instructive.

BOOKS, ETC., RECEIVED.

The Treatment of Fractures. By Charles Locke Scudder, M. D., Surgeon to the Massachusetts General Hospital, Out-patient Department, etc. Assisted by Frederic J. Cotton, M. D. Second Edition, Revised. With 611 Illustrations. Pp. 9 to 457. Philadelphia and London: W. B. Saunders & Company, 1901. [Price, \$4.50.]

A Text-book of the Diseases of the Nose and Throat. By D. Braden Kyle, M. D., Clinical Professor of Laryngology and Rhinology, Jefferson Medical College, etc. With 175 Illustrations, 23 of them in Colors. Second Edition. Pp. 5 to 646. Philadelphia: W. B. Saunders & Company, 1901. [Price, \$4.]

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, etc. Assisted by H. R. M. Landis, M. D., Assistant Physician to the Out-patient Medical Department of the Jefferson Medical College Hospital. Volume I. Pp. 4-17 to 440. Philadelphia and New York: Lea Brothers & Company, 1901.

Pulmonary Consumption, Pneumonia, and Allied Diseases of the Lungs: Their Ætiology, Pathology, and Treatment, with a Chapter on Physical Diagnosis. By Thomas J. Mays, A. M., M. D., Professor of Diseases of the Chest in the Philadelphia Polyclinic, etc. Illustrated. Pp. 8 to 539. New York: E. B. Treat & Company, 1901. [Price, \$3.]

The Annual Eclectic of Medicine and Surgery. Record of 1897 and 1898. Volume VIII. Edited by John V. Stevens, M. D., Professor of Diseases of the Nervous System in Bennett Medical College, Chicago, etc. Pp. 3 to 522. Cincinnati: Scudder Brothers Company, 1901. [Price, \$2.]

Manual of the Diseases of Children. By John Madison Taylor, A. M., M. D., Professor of Diseases of Children, Philadelphia Polyclinic, etc., and William H. Wells, M. D., Adjunct Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic, etc. Second Edition, thoroughly Revised and Enlarged. Illustrated. Pp. xvi-17 to 859. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, \$4.50.]

The Feeding of Infants. A Home Guide for Modifying Milk. By Joseph E. Winters, M. D., Professor of Diseases of Children, Cornell University Medical College. Pp. vii-47. New York: E. P. Dutton & Company, 1901.

Oral Sepsis as a Cause of "Septic Gastritis," "Toxic Neuritis," and other Septic Conditions. With Illustrative Cases. By William Hunter, M. D., F. R. C. P., Senior Assistant Physician, the London Fever Hospital, etc. Pp. 30. London and New York: Cassell & Company, Limited, 1901.

Studies in Human and Comparative Pathology. By Woods Hutchinson, A. M., M. D., Professor of Comparative Pathology and Embryology in the University of Buffalo, etc. Edited by Edward Blake, M. D. Pp. x-340. London: Henry J. Glaiser, 1901.

Miscellany.

A Memoir of the Late Dr. J. Henry Fruitnight.—At a meeting of the Northwestern Medical and Surgical Society, held on March 20th, Dr. Henry Ling Taylor presented the following: To attempt a full and just estimate of the character and services of any man is indeed a formidable—one might almost say a superhuman—undertaking. Let us content ourselves with the simple endeavor to register in brief outline the life history of our friend and to record some of the impressions which his daily walk and conversation made upon ourselves and upon others. Dr. Fruitnight was of pure German descent, his father and mother having come to New York from the kingdom of Hanover in the 'forties. John Henry Früchtnicht, the father, was an ex-guardsmen of the Hanoverian army, and for twenty years served in Troop A of the New York State militia. His retail grocery business was seriously affected by the panic of 1857, and the children, brought up in somewhat straitened circumstances, early learned the lesson of helpfulness and independence. The mother died about eight years ago, at the age of sixty-four, and the father passed away last autumn in his eighty-fourth year. Both parents and an only sister had for many years made their home with the doctor; a younger brother died in early manhood many years ago, after beginning the practice of medicine. John Henry was born in New York, on or near Broome Street, on November 5, 1851. He attended the public schools, graduating at the old Thirteenth Street school, which had a great reputation in those days under Principal Hunter, now president of the Normal College. In 1872 Dr. Fruitnight took his A. B. degree at the College of the City of New York. During his course he had shown special aptitude for mathematics and languages, and had added to the English and German he already possessed an excellent knowledge of French. During the last two years at college he had assisted himself by teaching in the city night schools, and continued this work, as well as private tutoring in German and mathematics, during his medical course. Soon after leaving the city college he began the study of medicine under our fellow member, Dr. Charles E. Leale, attending lectures at the Bellevue Hospital Medical College, where he received his degree of M. D. in 1875. Those who remember him in his school and college days describe him as a bright, industrious student, gifted with a remarkable memory, quiet and somewhat shy, but of a clean, straightforward, loyal nature, qualities which distinguished him throughout his life.

Dr. Fruitnight began the practice of medicine in 1875 in what was then the upper West Side, on Fifty-third Street, near Eighth Avenue, and with the cooperation of his late instructor and other friends he acquired a profitable practice within a few months. In the following year he was married to Gertrude Huggins, who died three years later. In May, 1881, he married Mary Augusta Stewart, who, with one son, H. Stewart Fruitnight, survives him.

In the first years of his practice Dr. Fruitnight was

especially interested in obstetrics, and up to 1890 had written a dozen papers on obstetrical and gynæcological subjects, most of which appeared in the *American Journal of Obstetrics*. Before that date he had attended upward of 1,000 obstetric cases, and a colleague informs me that three obstetric calls in one night were not a rare occurrence. As his general and obstetric practice had become very large, perhaps for some years the largest on the West Side, he withdrew as much as possible from midwifery, but continued to do considerable gynæcological work. Before this he had become deeply interested in the diseases of children, and it is as a pædiatrist that he is most widely known to the profession. He had served as physician to the New York Foundling Asylum clinic from 1879 to 1881, and was for many years actively interested in the work of St. John's Guild, having been one of the founders and attending physicians of its city hospital for children. He was also an original member and the first secretary of the Pædiatric Section of the Academy of Medicine, established in 1887, and was its chairman in 1897 and 1898. He was a charter member of the American Pædiatric Society, was very regular in his attendance at the annual meetings, and rarely failed to present one or more original contributions, most of which were published in the *Archives of Pædiatrics* and in the *Transactions*. He was also a prominent member of the New York Academy of Medicine, its delegate to the State society from 1880 to 1883, a member of its obstetric as well as of its pædiatric section, and completed five years' service on its membership committee in 1899. At one time or another he was a member of the Medical Society of the County of New York, the Society of Medical Jurisprudence and State Medicine, the Medicolegal Society, the Medico-surgical Society, the Bellevue Hospital Alumni Association, the American Academy of Medicine, the New York Obstetrical Society, the New York Physicians' Mutual Aid Association, several of the International Medical Congresses, the Metropolitan Museum of Art, the New York Historical Society, the Alumni of the City College, and the Colonial and New York Athletic clubs. Dr. Fruitnight's membership in the Northwestern Medical and Surgical Society dates back to 1876, and the important place he held among us is known to you all. He rarely missed a meeting, was always ready to do work assigned, whether as officer, on a committee, or in the preparation of a paper, and it was largely due to him and to members like him that the social and fraternal feeling in our society has always been such a prominent and attractive feature. He acted as our secretary from 1881 to 1885, and as our president for the year 1886. Modest and retiring in manner and in feeling, never thrusting himself forward, yet nearly always holding positive and well-digested opinions on the topics which came up for discussion, his remarks were remarkably clear, concise, and practical, because based on a mature judgment and an extensive and well-ordered experience.

Dr. Fruitnight was an excellent diagnostician and clinician: he carefully studied his cases, was most conscientious and assiduous in attendance, and enjoyed to a remarkable degree the confidence and affection of his patients. In therapeutics, he was inclined to be conservative, relying on well-tested remedies and methods, but was always open-minded and eager to learn.

Never a very robust man after two serious attacks of septic pneumonia in his student days, the amount of work that Dr. Fruitnight accomplished was simply prodigious. His daily rounds took him to the extremes

of the West Side, and upwards of thirty daily visits were not unusual for him. He enjoyed besides a large consulting practice, much of which came from neighboring States. He was active in many of the societies already enumerated, and his published work comprises over forty titles. As a matter of fact, he went to the extreme limit of his strength in his devotion to his profession, and his vacations were short and infrequent, his relaxations and outside interests few. He appreciated good literature, and in such intervals as he could snatch from his work he was fond of reading the standard English and German authors. He was also devoted to his church, and served for twenty years on the board of deacons of the Central Presbyterian Church, during the last fourteen as president.

In spite of curtailing night work in later years, the strain proved too severe, and it was evident to some of us two years ago that he was failing. With undaunted courage, though perhaps faulty judgment, he continued his work to within a few days of his death, which took place on December 19, 1900, in the forty-ninth year of his age.

We often hear it said of a man who has been fairly successful how much more might he not have accomplished had he only taken a different course or lacked certain elements of weakness. In Dr. Fruitnight's career, on the contrary, we see what intelligent industry and conscientious devotion may accomplish. Singularly free from personal blemish, large or small, his well-ordered and blameless life was given freely and gladly in useful service. In an age and in a profession often accused of self-seeking and of devotion to material interests, though without independent means, he kept his ideals high, and the monetary side of his profession never dominated him. Business-like in his methods, reasonable in his charges, unalterably opposed to the prostitution of medical charity, he was incapable of bias from social or financial considerations, and freely and conscientiously gave his services whenever and wherever they were required. He was in fact one of the most unselfish of men, always ready to do a favor and slow to ask one, and consistently spending time, strength, and his best thought in the service of others.

A pædiatrist of world-wide reputation said in a recent letter: "I know of no one who, without being unusually gifted intellectually or beyond the endowments of most of us, through his honest industry, modest behavior, and sense of duty and responsibility, made a more favorable impression on the large number of those who knew him, and made more friends in and out of the profession."

This deliberate and authoritative judgment is most suggestive, for few will doubt that the world is quite as much in need of men unusually high of aim and broad of sympathy as of men of unusual intellectual calibre. Indeed, it is only the refined intelligence warmed by generous emotion that is capable of persistently putting aside those things for which most men strive, and of putting the emphasis of life upon personal character, good citizenship, and service to others. What his life was he made it from deliberate choice and with his own strenuous endeavor; whoever came into contact with it could not fail to be impressed with its integrity, its consistency, its steadfast devotion to the highest aims. His published work, the lives he saved for the community, the affection he leaves in thousands of modest homes where he ministered as physician and as friend are his enduring monument. We who knew him well in both relations would bring also our tribute of respect and

devotion, bearing witness to his attainments and skill, to his singularly kind, gentle, and helpful nature, and to his remarkable personal and professional loyalty.

Precocious Obesity.—According to Chauffard (*Journal de Médecine*, March 10, 1900; *British Medical Journal*, December 22, 1900) much fatness in a child is not a sign of health, but one of degeneration, and unless treated may end fatally. Chauffard had under his care a man, aged thirty-four years, of middle height and of very excessive obesity. From early childhood this had been the case, and it was discovered that there were several instances in his family of hereditary obesity. Examination showed considerable cardiac embarrassment and dyspnoea. He was put on milk diet alone, together with some doses of thyroid extract, and under this treatment he lost a good deal of weight in three weeks. He returned home and resumed his ordinary diet, on which he regained a kilogramme *per diem*. It was found that his heart was failing, and had ceased to react to digitalis and other tonics. The patient died of asystole. It is difficult to state exactly the pathogenesis of congenital obesity. In some cases, apparently, there is too rapid an assimilation of nutritive material, while in others combustion is not sufficiently rapid. It has also been supposed that there is some peculiar lipogenic ferment, but the evidence of this is not sufficient. In constitutional cases treatment is very much more difficult, especially in view of the fact that the patients are not infrequently gouty, diabetic, or the subjects of renal disease. A great deal also depends on the state of function of the heart and kidney, which are indeed the indications of most importance. Not infrequently there is tachycardia or arrhythmia. On post-mortem examination, the muscular structure of the heart is generally found to be considerably affected. A point that has, so far, not been sufficiently studied is the thyroid gland. In the cases quoted by the author, this organ was double the normal size, and its structure profoundly altered, there being a condition which could best be described as a hypertrophic cirrhosis. In such cases the main line of treatment is, first, to impress on the patient the absolute importance of reducing his weight, otherwise the heart may be suddenly hampered and give way. Next, to put him on a very limited diet, chiefly milk, and to order a carefully graduated scale of exercises. It is important that it should be judiciously increased, and it may be combined with massage. The administration of thyroid extract is undoubtedly of use, according to the author, but its action must be carefully watched. It is contra-indicated in cases where there is severe cardiac embarrassment. When given, it should be taken for a week at a time, followed by the administration of Carlsbad salts. If taken too frequently the result may be cardiac failure.

Experimental Tuberculosis.—Dr. R. R. Dinwiddie (*Journal of Comparative Medicine and Veterinary Archives*, January) thus concludes an interesting serial article on Experimental Tuberculosis, Human and Bovine, in the Domestic Animals:

"In reviewing the results of the foregoing experiments, considered in their relation to agricultural or veterinary science rather than to comparative pathology, I may formulate the following conclusions, which seem to be thoroughly established by the evidence which we now possess:

"1. Toward tubercle bacilli of human consumption, pigs, sheep, and cattle show a susceptibility in the order

named. Pigs may obtain a genuine progressive tuberculosis by infection from man, while cattle are practically insusceptible.

"2. As regards tubercle bacilli of bovine tuberculosis, all three species are alike susceptible to the inoculation disease.

"3. The excess of virulence of the bacilli of cattle tuberculosis over that of human consumption, previously demonstrated in cattle and rabbits, holds good, also, for pigs and sheep—for all susceptible animals, practically, on which the test has so far been made.

"I may add to this, in conclusion, an opinion of my own, forced upon me largely by the experience I have had in these studies of experimental tuberculosis in animals, namely, that the conditions of environment, in their influence on the initiation and progress of tuberculosis in cattle and in mankind as well, have been and are even now greatly underestimated. Among the unfavorable influences, I attribute much the greatest importance to the breathing of vitiated air—disregard of ventilation—in houses and stables."

Recovery from Pernicious Anæmia.—Dr. W. Hunter (*British Medical Journal*, February 16th) recently showed to the Medical Society of London a man who had completely recovered from pernicious anæmia. For ten years he had suffered from purulent discharge from the gums, with recurrent pain in the tongue and stomach, attended with digestive disturbance and progressive anæmia. Ultimately the red corpuscles in his blood reached only twenty-seven per cent. of the normal, the hæmoglobin only thirty-five per cent. His urine showed the characteristic dark, smoky tint, and he had irregular fever with numbness and tingling of the fingers. Under treatment by oral and gastric antiseptics (chiefly carbolic-acid solution for the mouth, and bichloride of mercury in small doses) he steadily improved; four injections of antistreptococcus serum had been administered in three weeks with apparent benefit. The red corpuscles had thus been increased forty per cent., and further treatment by the administration of liquor arsenicalis had brought the blood condition to: red corpuscles = 95 per cent., hæmoglobin = 106 per cent. Cases of pernicious anæmia, Dr. Hunter said, often improved under arsenic alone, but invariably relapsed, and he considered this case the most hopeful he had yet seen. He attributed great importance to a septic condition of the mucous tract in the causation, and to antiseptic measures in the treatment. From this last statement, however, Dr. J. Broadbent dissented, and related several cases to the contrary.

Gonorrhœa in the Genital Tract of a New-born Child.—Aichel (*Hegar's Beiträge*, Vol. ii, Part 2, 1900; *British Medical Journal*, November 17th) observed this case. The mother had gonorrhœal discharge from the urethra, verified by microscopic examination. Four days after birth the infant had swelling, with redness about the vagina; from that date to the tenth day there was purulent discharge which for the three succeeding days was sanious. The infant's general condition remained good, no inflammation of the surrounding connective tissue followed. Plenty of gonococci were detected in the pus, which when cultured yielded diplococci and *Bacillus coli communis*. Aichel suspects that gonorrhœa of the vulva may be frequent in the infant, and that it ascends quickly, the vulva healing. It may explain the bleeding and erosions not rare in infants; also it may cause the so-called "congenital" atresia vaginae.

Original Communications.

THE ACTIVE PRINCIPLES OF DIGITALIS LEAVES.

BY JOSEPH W. ENGLAND, PH. G.,

PHILADELPHIA.

THE more important features of Dr. Leon L. Solomon's paper upon A Clinical Analysis of Digitalis and its Preparations, calling special attention to the glucosides and more especially to digitoxin, as contained in a recent issue of this journal, are, in my judgment, the contrasts shown between the physiological actions of digitalis derivatives and the clinical claims made for digitoxin. The clinical studies were made with "digitalin, German-Merck," and "digitoxin—Merck"; for the former the formula $C_{35}H_{56}O_{14}$ is given, for the latter, $C_{34}H_{54}O_{11}$, though the qualifying statement is made that while these formulæ "are now pretty definitely established, this is not absolutely so."

Dr. Solomon asserts, in brief, that digitoxin is the chief constituent of digitalis leaf, and that the latter should be standardized in terms of its contained digitoxin; and, further, that digitoxin is superior to digitalin as a diuretic, since it more promptly and certainly dilates the renal vessels while stimulating the heart, manifesting such effects within twelve hours. He quotes Masius as saying that the action of digitoxin is "certain, quick, and energetic," and Van Aubel as stating that digitoxin is "the most prompt, reliable, and powerful derivative of digitalis."

The chemistry of digitalis leaves has been in a state of confusion for nearly three quarters of a century. Various so-called active principles have been isolated, from time to time, nearly all of which have been found to be varying mixtures. The digitalins of Homolle, Quevenne, Walz, Kosmann, and Nativelle, the "French" digitalin, and the "German" digitalin, have been shown to consist of a number of compounds. Merck's "German" digitalin—referred to by Dr. Solomon as a definite compound, and probably the most uniform and reliable product of its class—is a mixture, as shown by the following quotation from a letter by Merck & Company to the writer: "Digitalin, 'German,' is a mixture of the digitalis glucosides that enter into solution in the preparation of the aqueous infusion of digitalis. According to Schmiedeberg's investigations, it consists preponderantly of digitalein, with small proportions of digitin, digitonin, and Schmiedeberg's digitalin. It occurs as a yellowish-white amorphous powder that is soluble in water and in alcohol, but practically insoluble in chloroform and in ether. The process of its manufacture consists in precipitating it from infusion of digitalis in the form of its difficultly soluble tannate; then liberating it from this compound by ap-

propriate means, and finally subjecting it to further purification."

The work of Schmiedeberg in 1874 (*Arch. für exp. Pathol. und Pharm.*, 1874, 16, *vide Pharm. Journ. and Trans.*, 1875, 741) attracted very general attention. The results of his experiments seemed to indicate that the active principles of digitalis leaves were a digitalin, digitoxin, digitonin, and digitalein. He discovered digitoxin, obtaining it from the leaves. The digitalin he examined was prepared from commercial digitalin made from seeds, and it was assumed that the digitalin, digitoxin, digitonin, and digitalein present in the seeds were the same as those present in the leaves. The digitalin isolated has been known as "Schmiedeberg's digitalin."

In this connection it is interesting to give the following data, taken in part from a paper by the writer upon the subject of Digitoxin as the Active Principle of Digitalis, as contained in the *American Journal of Pharmacy* for 1899:

In 1892 Kiliani reported (*Archiv. der Pharm.*, 230, p. 250, *vide Pharm. Jour. and Trans.*, June 25, 1892, p. 1061; *Am. Journ. Pharm.*, 1892, pp. 415, 422) that "the digitalin of Schmiedeberg is a distinctly individual substance which possesses, in a marked degree, the characteristic property of acting upon the heart"; that "analysis gave results agreeing with those obtained by Schmiedeberg, which lead to the formula $C_5H_8O_2$ "; that the digitalin is very definitely split up by diluted hydrochloric acid into digitaligenin, glucose, and digitalose, and that the pharmacological results obtained by Professor Boehm, of Leipzig; Dr. Motter, of Munich, and Professor von Ziemssen, of the Munich Hospital, with Schmiedeberg's digitalin were characteristic of digitalis. Kiliani prepared his Schmiedeberg's digitalin from digitalis [whether from leaves or seed it is not stated.—J. W. E.] and it was named "Digitalinum verum." In 1895 Kiliani (*Archiv der Pharm.*, 233, 299, *vide Pharm. Journ. and Trans.*, 1895, 29) published further details regarding the "Digitalinum verum," the material for examination having been prepared from purified commercial digitalin made from digitalis seed.

After this, however, Kiliani radically changed his views and claimed that Schmiedeberg's active principles were, in several instances, impure products—that is, mixtures; that digitalis leaves contained neither digitonin nor digitalin, but the glucoside digitoxin; that the glucosides digitalin and digitonin are present in the seeds, but not in the leaves; that digitonin is quite insoluble in water, and that the existence of digitalein is extremely doubtful. In other words, that digitoxin is the only important constituent of digitalis leaves (*Archiv d. Pharm.*, 1892 to 1896, inclusive, through *American Druggist*, 1897, 68).

In 1895 (*Arch. d. Phar.*, 1895 (No. 4), 311, 320, *vide A. Ph. A. Proceedings*, 1896, 825) Kiliani reported obtaining from digitalis leaves a substance identical with, or closely related to, the digitoxin of Schmiedeberg,

and provisionally termed it *b* digitoxin. It was present to the amount of 0.1 per cent., was glucosidal, and crystalline. In 1896 Kiliani reported (*Arch. d. Pharm.*, 234, No. 7, September 10, 1896, 481, 489, *vide A. Ph. A. Proceedings*, 1897, 735) that experiments had shown that Schmiedeberg's digitoxin and the digitoxin which he had isolated during the previous year and provisionally named *b* digitoxin, were positively identical.

In 1897 C. C. Keller's conclusions (*Berichte d. Deutsch. pharm., Gesellsch.*, 7, 125, *vide Pharm. Journal*, *vide American Druggist*, August 10, 1897, 70) on the subject of the chemical principles of digitalis leaves were that they contain a digitalin, a digitoxin, and a digitonin identical with products from digitalis seeds, but in somewhat different proportions, the amount of digitoxin in the seeds being much smaller than that in good leaves, but varying much in different samples of leaves, or from 0.26 to 0.62 per cent. Keller writes that the unsatisfactory results obtained with the digitalin prepared according to the method described by Kiliani (see *Pharm. Journal*, 55 (1896), 29) have again attracted attention to digitoxin, which latter is alleged to be the most potent constituent of digitalis leaves, and then makes a plea for standardizing digitalis preparations on the basis of the amount of digitoxin they contain.

Replying to a criticism by Keller of his results of investigation concerning the constituents of digitalis leaves, Kiliani then claimed that digitalis leaves contain, besides digitoxin, a crystallizable glucoside in considerable quantities, which, like digitoxin, is soluble in chloroform, and which also produces, with solution of iron in glacial acetic and sulphuric acids, the blue color regarded by Keller as characteristic of digitoxin. Kiliani proposed for the new substance the name of digitophyllin, and gave its physical and chemical properties (*Arch. d. Pharm.*, August 17, 1897, 425-429, *vide Proc. A. Ph. A.*, 1898, 795).

Professor Boehm, while in general acknowledging the value of Keller's method for the estimation of digitoxin, warns against an absolute reliance upon it, as, in his opinion, the efficacy of digitalis depends not alone on the digitoxin present, but rather on the sum total of all its constituents (*American Druggist*, June 25, 1898, 342; from Gehe & Co.'s *Bericht*).

According to Kiliani, he has never been able to find in the leaves of digitalis either the so-called *Digitalin verum* (*i. e.*, Schmiedeberg's digitalin) or (probably) digitonin (*Arch. d. Pharm.*, 1897, 425-429, *vide Proc. A. Ph. A.*, 1898, 795), while Keller (*Ueber die Werthbestimmung von Drogen und galenischen Präparaten*, Diss. Zurich, 1897) states that both *digitalin* and *digitonin* are present. M. Cloetta has gone into this knotty problem, and finds that the leaves contain the same *digitalin*, *digitoxin*, *digitonin*, and *coloring matter* as the seeds. He did not find any *digitalein* in the leaves. The seed contains much more *digitalin* than *digitoxin*, while in the leaves the reverse obtains (1898, *Arch. f. exp.*

Pathol. u. Pharm., 41, 421, *vide Am. Jour. of Pharm.*, 1899, 90).

Quite recently more light has been thrown upon the chemistry of digitalis leaves, and a very interesting paper has been written upon the subject by A. R. L. Dohme, Ph. D., for the *Druggist's Circular* (January, 1901, 4), from which the following information is taken:

In 1898, Kiliani ascertained the composition of digitoxin ($C_{34}H_{54}O_{11}$) by saponifying it into digitoxigenin ($C_{22}H_{32}O_4$) and digitoxose ($C_6H_{12}O_4$). He also determined the composition of digitalin ($C_{35}H_{56}O_{14}$) by saponifying it into digitaligenin ($C_{22}H_{30}O_3$), digitalose ($C_7H_{14}O_5$), and *d.* glucose ($C_6H_{12}O_6$). In his work he used the principles made from digitalis seeds, and claims that the glucosides obtained from the leaves are different from those of the seed; thus, the digitoxin from the leaves had the formula $C_{28}H_{46}O_{10}$; that from the seeds had the formula $C_{34}H_{54}O_{11}$. The so-called "German digitalin" contains, he asserts, about 50 per cent. of digitonin.

Digitalis seeds are largely used in Germany for the preparation of digitalis principles. Hence, continues Dr. Dohme, we know, apparently, not very much about the glucosides of digitalis leaves, the main work so far having been done upon preparations made from the seed. This appears rather odd since, although the manufacturers of digitalin preparations do use the seed, as it appears, the pharmacist uses practically exclusively the leaves of the drug, and wants to know about them and what glucosides and other substances they contain. In a communication recently received from Professor Kiliani, he states that digitoxin is by no means the only active principle of digitalis, although no doubt one of the most active. In the leaves are contained besides digitoxin, *digitalein* very largely, and most probably *digitalin*. According to Professor Boehm, he says further, digitoxin is not a complete substitute for an infusion of the leaves, as this contains principally *digitalein*, which most probably produces most of the physiological effect of the infusion. There is no reliable method of assaying digitalis for digitoxin, according to Kiliani, for he maintains that Keller's method is unreliable. *Digitalein*, he further says, is too incompletely characterized and known and too easily decomposable to enable one to readily discover a method of assaying digitalis for it. To sum up the status of digitalis chemistry to-day, writes Dr. Dohme, we know little about the glucosides of the leaf, although we do know considerable about those of the seed, due to the unfortunate fact that investigators use the preparations of digitalin apparently made by manufacturers who use the seed in making their products. As the seed contains no *digitalein*, we see but little mention of this in the literature, and correspondingly more of digitonin, digitalin, and digitoxin. We know the composition and properties of the digitonin, digitoxin, and digitalin and digitophyllin of the seed, but hardly as much of the digitoxin, *digitalein*, and digitalin

of the leaf. There is hence quite a field for work in the study of the glucosides of digitalis leaf, and the results, when they come out, will probably not agree with those of Kiliani, whose work has been on products of the seed, which he maintains are different, as we have seen, from those obtained from the leaf. The problem before those who are interested in the assay of digitalis leaf, concludes Dr. Dohme, is to obtain the various glucosides therefrom in quantity and study them, after carefully purifying them, both chemically and physiologically. All such as are found to be therapeutically active and valuable should be carefully studied and a method worked out that will enable us to determine all the same quantitatively. What has been done on digitalis preparations heretofore should be left unconsidered in this work, as it will probably tend more to confuse than to aid in the work, inasmuch as it applies to different preparations. It would appear that here is the opportunity of some ambitious American pharmaceutical chemist to help us out of a peck of trouble and put us on *terra cognita* in a domain distinctively in need of a firm foundation and a scientific structure.

The assertion made by Dr. Solomon that digitoxin is the chief constituent of digitalis leaves is not a new one. It was advocated years ago by Kiliani, but abandoned later. The formula given for the digitoxin used by Dr. Solomon, in his clinical work, is $C_{34}H_{54}O_{11}$, and this Kiliani has shown is the formula of the digitoxin obtained from the seed; the digitoxin of the leaves has the formula $C_{28}H_{46}O_{10}$. The digitoxin Dr. Solomon used was presumably made from the seed, and, if Kiliani is correct, cannot represent the leaves.

Now, apart from the question of chemical composition, if it be true that digitoxin represents the medicinal value of digitalis leaves, it follows that it should give, clinically, all the therapeutic results yielded by the leaves or preparations, and as promptly. Further, since digitoxin is wholly insoluble in water, the infusion of the leaves should be wholly destitute of the representative principle, and consequently of medicinal worth; yet there are physicians who use the infusion of the leaves to the exclusion of its other preparations. Against this fact it is contended (*Apoth. Ztg.*, 1899, 178, *vide Proc. A. Ph. A.*, 1899, 521) that while pure digitoxin is insoluble in water, yet in the presence of digitonin it becomes water-soluble, which, to say the least, is remarkable, if true.

Now, as the writer has previously stated (*Amer. Journ. Pharm.*, 1899), while digitoxin may be a most distinctive chemical substance, it is very clear, from the experiments of Dr. Karl Hofmann (*Wiener klinische Wochenschrift*, 1896, No. 42, 939, *vide American Journal of the Medical Sciences*, 1897, 107), and the pharmacological results already obtained by the writer with his tincture of "fat-free digitalis," that the entire therapeutic activity of the leaf cannot depend upon digitoxin.

Dr. Hofmann reports the clinical use of digitoxin in

fifty-nine cases—three instances by the mouth, thirty-seven by subcutaneous injection, and nineteen by enemata. He confirms previous investigators in referring to its insolubility in water and the vigorous local irritation caused by its use. The injections are followed by local burning pain, lasting from one half to three or four hours, and redness for two or three days, which is sensitive to pressure. Inappetite, nausea, vomiting, and pain in the epigastrium occurred in one fourth of the cases, whether subcutaneous injections or enemata were administered. The most remarkable fact, however, was the *length of time* reported as having elapsed before physiological effects were manifested. After the first dose, six hours were required to increase pulse-force and lessen dyspnoea, while twelve hours were required to produce diuresis. With enemata these changes required twenty-four to thirty-six hours.

These results have been confirmed by the recent work of Dr. J. P. Arnold and Dr. H. C. Wood, Jr., in a paper published in the *American Journal of the Medical Sciences*, August, 1900, entitled A Comparative Study of Digitalis and its Derivatives, in which it is stated that "digitoxin is not to be recommended for human medication on account of its irritant action, which makes it liable to upset the stomach when given by the mouth, or to cause abscesses when given hypodermatically, and on account of its insolubility, which renders it slowly absorbed and irregularly eliminated, having a marked tendency to cumulative action."

The "tincture of fat-free digitalis" referred to (*American Journal of Pharmacy*, July, 1899) is a preparation originated by the writer some years ago for use in the Philadelphia Hospital. It is made by exhausting freshly ground digitalis leaves with purified petroleum benzin, drying the residue thoroughly by exposure to air, percolating with diluted alcohol, and neutralizing the percolate with ammonia water; the strength of drug is the same as the official tincture of digitalis. The product is a deep reddish-brown, almost black liquid, of not unpleasant odor and purely bitter taste. It has not the acrid taste of the official tincture, and, unlike the latter, remains transparent on dilution with water. The benzin treatment removes the fat, and probably all the nauseating and odorous principles, and the ammonia treatment neutralizes the free fatty acids present in the finished tincture. All the proximate principles are made water-soluble and not partly so, as in the official product. This feature is of marked value, because all compounds must be made water-soluble before they can be absorbed by the tissues. Increased cellular absorption means increased assimilation, as clinical experiments with this tincture have proven.

Fifteen cases in the Philadelphia Hospital were treated with the fat-free tincture and with the official tincture, and the time, in minutes, required to induce first effects and full effects, along with the work and beats reduced, were noted. Practically, the primary ef-

fects of the fat-free tincture were manifested in 15 minutes, and the maximum in 45 minutes; while with the official tincture primary effects were manifested in 30 minutes, and maximum in 60 minutes. The duration of the effect was the same in both cases—30 minutes. The pulse reduction in work done was slightly greater with the fat-free tincture than with the official. The fat-free tincture was much more rapidly absorbed than the official. No special difference in the time of absorption between hypodermic injections and mouth administrations was observable, but when the tincture was given hypodermically the pulse reduction seems to have been greater with the fat-free tincture, though not extending over any greater length of time.

From a therapeutic point of view, it is clearly impossible to believe that a drug or preparation that yields physiological effects in about thirty to sixty minutes has for its most important constituent a proximate principle (digitoxin) whose physiological effects are not manifested in from six to thirty-six hours.

It seems clear from the properties of digitoxin—its difficulty of absorption, the length of time necessary to yield cardiac and renal effects, its slowness of elimination, and the relative rapidity of absorption of digitalis tinctures, that digitoxin cannot be the most important therapeutical principle of digitalis leaf. The severe local pain following hypodermic injections of digitoxin, the prolonged sensitiveness of injected tissues, and the slowness of physiological effects indicate a great difficulty of absorption and assimilation. Dr. Solomon states in his paper that after discontinuing the use of digitoxin its influence persists from eight to ten days, and that, given hypodermically, "a very hard infiltration œdema usually follows the injection, until after many pricks of the needle the tissues about the point of puncture become stiff and rigid, interfering somewhat with the function of the part." In view of these facts, is it not probable that the water-insoluble digitoxin is absorbed, not as digitoxin, but as a water-soluble decomposition product or products? Digitalis is sometimes cumulative in action. When taken for a long time there are occasionally exhibited symptoms without any increase in the use of the drug. This has been thought to be due to the fact that the proximate principles of the drug were not excreted by the kidneys as fast as absorbed, and that they therefore accumulated in the body. But from the experiments referred to above, it would seem to be more reasonable to believe that cumulative action, where existent, is due to the slow absorption and elimination of digitoxin. With a bed-patient, a good tincture of digitalis, for example, should yield primary effects in from 15 to 30 minutes, and full effects in from 45 to 60 minutes. Digitoxin, however, on hypodermic injections, requires, before any effects are shown, 6 hours and over. Now, if a large number of doses of a digitoxin-containing tincture of digitalis be given, and the use of the drug be withdrawn, may not the accumulated digitoxin

(of the tincture) by absorption give rise to the dangerous symptoms which are called the cumulative effects of digitalis?

The chemistry of digitalis leaves cannot be regarded as being satisfactorily settled. If Kiliani's claim that the glucosides of the leaves are different chemically from those of the seed is a fact—and it seems singular that such a difference should exist between the glucosidal principles of the leaves and the seed of the same plant—it means that equally as great differences in the physiological activities of the principles may exist, and these differences, if existent, would serve to explain much of the seeming confusion that has heretofore obtained in the reports made by different investigators upon the chemical nature and the physiological properties of digitalis principles. New investigations are needed upon the glucosides prepared from the leaves (not from commercial products obtained from the seeds); and these investigations should be made along new lines, leaving unconsidered, as Dr. Dohme urges, all the work that has been heretofore done upon digitalis principles.

415 N. THIRTY-THIRD STREET.

THE COMPARATIVE PATHOLOGY OF THE JEWS.

By MAURICE FISHBERG, M. D.,

NEW YORK.

(Concluded from page 543.)

Mental diseases occur more frequently among the Jews than among non-Jews. It has been asserted by many competent and reliable observers that the Jews supply proportionately from two to five times more mental defectives than the Christians. Thus Lombroso (44) shows that the Jews in Italy had, in 1869, one lunatic to 391 of their people—*i. e.*, almost four times more than the Catholics in that country. Verga confirmed this in 1879, and stated that there were:

One lunatic to	1,775 Catholics;
" "	" 1,725 Protestants;
" "	" 385 Jews.

Meyr shows that in 1871 there were:

<i>In Prussia:</i>	
To 10,000 Christians.....	8.7 insane
To 10,000 Jews.....	14.1 "
<i>In Bavaria:</i>	
To 10,000 Christians.....	9.8 insane
To 10,000 Jews.....	25.2 "
<i>In the German Empire:</i>	
To 10,000 Christians.....	8.6 insane
To 10,000 Jews.....	16.1 "

Dr. Sikorsky and Dr. Maximoff bring the following data about the troops in Kieff, Russia, during 1895-1896 (45):

Russians.	0.91 per cent. of insane
Polish.	0.92 " " "
Mohammedans.	1.06 " " "
Jews.	2.19 " " "

According to German statistics (46) there is one idiot

In Silesia:

To 580 Catholics; to 408 Protestants; to 514 Jews

In Wurtemberg:

To 4,113 Catholics; to 3,207 Protestants; to 3,003 Jews

And one lunatic:

In Bavaria:

To 908 Catholics; to 967 Protestants; to 514 Jews

In Hanover:

To 528 Catholics; to 641 Protestants; to 337 Jews

In Silesia:

To 1,355 Catholics; to 1,264 Protestants; to 624 Jews

In Wurtemberg:

To 2,006 Catholics; to 2,028 Protestants; to 1,544 Jews

In a recent study of 1,000 cases of insanity at the Colney Hatch Asylum in London, Mr. C. F. Beadles (47) observes that "by those who come in contact with the (Jewish) race in hospital and private practice, the men are looked upon as neurotic and the women as hysterical. Neurasthenia, and all that this term implies, would seem to be a common complaint amongst those seeking medical aid. Hereditary insanity probably figures high in the race, but it is impossible to get at the proper proportions, which this holds." Mr. Beadles then shows that there was found to be a great preponderance of general paralysis among Jewish males; over twenty-one per cent. of all the male Jews admitted being subjects of that disease, while the proportion of cases of general paralysis among all the males admitted to the hospitals for the insane in England and Wales is thirteen per cent. "It is evident," says Mr. Beadles, "that among the Jewish males, admissions for general paralysis are sixty per cent. more frequent than among the English and Welsh." No such disparity has been observed in Jewesses, although insanity following childbirth is more common among them than among others—namely in fifteen per cent. of all the Jewish females admitted to the Colney Hatch Asylum, as compared with 6.18 per cent. among the non-Jewish patients. It was found that insanity appeared earlier in Jews of both sexes than in non-Jews; at thirty-seven years of age in Jews, as compared with forty-three years in Christians; relapse occurs twice as frequently in Jewish patients discharged from hospitals for the insane as in other patients. "The mental strain," says Mr. Beadles, "resulting from excessive zeal in acquiring riches, and the worry and annoyance which must invariably accompany the greed for worldly goods, doubtless play no small part in the mental breakdown of these people."

All the statistics show plainly the frightful disposition of the Jews to insanity and idiocy. We shall speak of the causes of this peculiarity of the Jews hereafter in this paper when discussing the causes of the comparative pathology of the Jews in general.

Lagneau's observations led him to conclude that the Jews suffered relatively more from epilepsy than Christians (47a), but other observers, particularly Charcot, have disproved this conclusion. Worms (47b) observed in the Jewish hospital in Paris, during a period of

twenty-five years (1865 to 1890), only 77 epileptics among 26,591 Jewish patients. Oser states that this is also the case in the Jewish hospital in Vienna. In the Salpêtrière, according to Charcot, there were observed only 39 epileptics during thirty-four years (47c).

It is a curious fact that infantile cerebral degeneration, or amaurotic family idiocy, or *agenesis corticalis*, a rare and fatal disease of infancy, occurs mostly among Jews; of the cases first reported, in which the nationality is stated, the patients have all been Jews. Lately some cases have also been reported among Christians. This disease is characterized by progressive mental and physical enfeeblement, associated with symmetrical changes of the macula lutea which are pathognomic.

It will be observed that, with the exception of amaurotic idiocy, just mentioned, and also of the cases of general paralysis from Colney Hatch Asylum, all the observers agree that the Jews are disposed to suffer mostly from functional nervous diseases. With organic nervous diseases, as tabes, the various organic degenerative diseases of the brain and spinal cord, the Jews are no more affected than non-Jews; on the contrary, some varieties of organic nervous diseases occur less frequently among Jews than among Christians. Thus Dr. L. Minor, of Moscow, discussing syphilis as a cause of tabes (48), shows that the Jews are infrequently affected by both these diseases. To substantiate his contention, he brings statistics of his 383 cases of nervous diseases, of which 269 were in Jews and 123 in Christians. From among the Jews, he found eight positive and three probable cases of syphilis; among the Christians, twenty positive and twenty-six probable cases of syphilis. Among the 260 Jewish patients, he met with two cases, and among the Christians four cases, of tabes. Among the Christians there was consequently five times more syphilis and tabes than among the Jews.

General paralysis was also found to be six times more frequent among the Christian than among the Jewish patients.

In order to have more statistical evidence, Dr. Minor asked Professor Kajewnikoff and Dr. Korsakoff for their cases, and found that among Professor Kajewnikoff's 2,403 patients of nervous disease, 347 of whom were Jews, there were sixty cases of tabes and forty-eight of general paralysis; sixty-five per cent. of previous syphilis was discovered in the patients suffering from both these diseases. None of these 347 Jewish patients were affected with tabes, and only three Jews had general paralysis.

Dr. Korsakoff found that, among his 2,610 patients, were eighty-nine Jews; with tabes were affected sixty-two Christians and four Jews. Sixty-five per cent. of the patients with tabes had syphilitic antecedents. Among the four tabetic Jews, three had syphilis positively. General paralysis was found in sixty-nine patients, including one Jew; there were syphilitic antecedents in seventy-two per cent. of these cases.

Dr. Minor summarizes these cases as follows:

4,700 Christians: 137 cases of tabes.....	2.9 per cent.
696 Jews: 6 cases of tabes.....	0.8 per cent.
4,700 Christians: 124 cases of general paralysis..	2.6 per cent.
696 Jews: 6 cases of general paralysis.....	0.8 per cent.

In a later communication (49) On the Comparative Pathology of the Nervous Diseases in Jews and Christians, Dr. L. S. Minor analyzes 3,214 cases of nervous diseases which occurred in his practice. Among these there were 1,480 Jews and 1,734 Christians. He arrives, in part, at the following conclusions:

I. So far as he could find from his cases, the Jews are no more predisposed than Christians to *all* the nervous diseases.

II. On the contrary, the most serious organic diseases of the brain and spinal cord, chronic inflammation of the cerebral blood vessels, kidney, etc., are far more frequently met with among the Christians than among the Jews. The more dangerous organic diseases of the nervous system, as tabes and general paralysis, are rare among the Jews.

III. The reason for this lies mainly, if not exclusively, in the fact that syphilis and alcoholism are more frequent among the Christians.

IV. From his cases he does not find that even the functional nervous diseases occur more frequently among the Jews than among the Christians.

V. Hysteria is more frequent among the Jews than among the Christians. Hysteria in the male is very frequent among the Jews.

The statistics of Mr. Beadles, of the Colney Hatch Asylum, are the only ones we could find in the medical literature that contradict the contention that Jews suffer mostly from the functional neuroses. Dr. George H. Savage, in discussing Mr. Beadles's paper, aptly remarked (50) that, in his experience, "there has been very little general paralysis either among the (Jewish) men or women. Just as other races are affected, general paralytics among the Jews have nearly all had some history of syphilitic degeneration. The forms of moral depravity common among Jews are very marked and disproportionate, and perhaps that is not altogether surprising, considering the history of the race."

The frequency of functional nervous diseases in the Jew, as we have seen before, is attested by most of the observers on both continents. He is most liable to the diseases of our age—neurasthenia and hysteria; he has the distinction of having his nervous system predominating over his muscular. The Jews are far less muscular than nervous, probably because they are the most brainy, having lived for centuries only on the products of their brains; and, therefore, having for two thousand years overstrained their nervous system, they very easily become disordered, "out of gear," and even collapse entirely; a fatigued organ is easily disturbed in its function.

"The nervous derangements which are the effect of psychic trauma," says H. Oppenheim (51). "explain to

some extent the reason why the Jewish race—after being persecuted and oppressed, mostly only tolerated among the nations, living in peace for short times only, and then again tormented—is suffering in such immense numbers from the neuroses and psychoses, and particularly hysteria."

Dr. F. Jolly (52), speaking of the frequency of hysteria and the neuroses in the Jewish race, says that "possibly the persecution the Jews had to undergo for centuries, and with this the frequency of consanguineous marriages, has been the chief cause of the degeneration of their nervous system."

Dr. Otto Binswanger (53), speaking of the fact that the Jews supply relatively the largest contingent of neurasthenics in Europe, says "that there are no ethnic causes in their production." "This fact can be explained to have its origin in other causes: the disproportion between the inadequate development of the body of the Jew, on the one hand, and his constant restless mental activity on the other, has a degenerative influence on the Jew's nervous system; the consanguineous marriages, which occur so often among the Jews, have also very much to do with their nervousness." In the same sense speak also Krafft-Ebing, Erb, Charles Féré, and many others, about the causes of the frequency of the functional neuroses among the Jews. We shall return soon to this subject again when discussing the causes of the peculiarities of the general pathology of Jews in general; meanwhile, we want to point out that those diseases which occur most frequently among the Jews, as diabetes and the functional neuroses, are ascribed by many authors, as Van Noorden, Stern, Jolly, Binswanger, Erb, and many others, to the frequency of consanguineous marriages. To the same cause have, at some periods in the world's history, been attributed the following diseases (54): phthisis and leprosy, idiocy, insanity, epilepsy, cretinism, hydrocephalus, abnormally-sized heads, prognathous jaws, hare-lip and cleft palate, rickets, goitre, chorea, deaf-mutism, sterility, tuberculous meningitis, ichthyosis, and a score or more of other diseases. We have found that the Jews, who intermarry quite freely, are not more subject to all those complaints, excepting, of course, diabetes, insanity, and the functional neuroses; to many of these affections, as phthisis, sterility, etc., they are even less susceptible than other nations who do not so freely intermarry. We are consequently of the opinion that consanguineous marriages have very little, if anything, to do with the predisposition of the Jews to diabetes and the functional neuroses. And, indeed, it is at present quite universally agreed that consanguineous marriages among healthy individuals are not *per se* productive of any disastrous results to posterity.

Of the great number of other diseases which were, at one time or another, supposed to have been of more frequent occurrence among Jews than among Christians, we will but name gout and chronic rheumatism, and also

various eruptions on the skin, especially psoriasis. French authors, as Charcot, Lancereaux, Féré, and many others, find a close connection between the neuroses and what they call "arthritisms" and "herpetisms," including under these names a number of diseases and conditions, as gout, lithæmia, chronic rheumatism, psoriasis, diabetes, gall-stones, nephrolithiasis, etc., all of which occur in people of a nervous diathesis. They describe all these affections as occurring very often among the Jews. "The pathological history of the Jewish race," says Charles Féré (55), "is particularly favorable for the observation of the following fact: Nowhere else do we see so clearly the close connection which exists between the neuroses and the arthritisms, which are especially represented by gout and diabetes and the nervous diseases. Neurasthenia manifests itself in the Jews in its most complex forms."

Physicians who practise extensively among the Jews do not generally notice that the Jews are more prone to herpetism, gout, etc., than Christians. The case is, as we have seen, different with the functional neuroses and diabetes.

Varicose veins, and particularly hæmorrhoids, occur very frequently among the Jews, probably more often than among Christians. It is a fact that can be attested by most of the physicians practising among these people, that a very great proportion of Jews who have passed the fourth decade have their hæmorrhoidal veins more or less enlarged. The various forms of visceral herniæ appear also to be very frequent among the Jews.

According to Dr. Hardy (56) and many others, Jews are more often affected by eczema than non-Jews; but dermatologists with extensive practices among Jews and Christians inform me that the Jews in the United States are not any more liable than any other nationality to this disease.

Of the affections of the eyes, the Jews are said to be more liable to blindness, colorblindness, astigmatism, trachoma, glaucoma, and, according to M. Hervé (57), there is a frequency of lacrymal tumors among the Jews, due to the narrowness of their nasal canal.

Concerning blindness, Dr. Herman Cohen (58) brings the following statistics for Bavaria:

	<i>Per cent.</i>
Among 10,000 Protestants.....	7.2 blind
" 10,000 Catholics.....	8.2 "
" 10,000 Jews.....	13.8 "

and for Prussia, in 1880:

	<i>Per cent.</i>
Among 10,000 Protestants.....	8.2 blind
" 10,000 Catholics.....	8.4 "
" 10,000 Jews.....	11.0 "

There are similar statistics showing the frequent occurrence of blindness among the Jews in the various other European countries.

According to the *Report of the Committee on Colorblindness* of the Ophthalmological Society of London (59), the Jews are more subject than the ordinary popu-

lation to colorblindness. Among 730 Jewish women examined, 3.1 per cent. were found affected; and among 949 Jewish males, 4.9 per cent. The report adds that the Jews were, on the whole, of a poor condition of life, and their defects were of pronounced character. Jacobs and Spielman (60) found no less than 12.7 per cent. of London Jews to be colorblind. Fuchs and many others mention that trachoma and glaucoma are very often met with among Jews. "In many countries the Jews are special sufferers from trachoma," says Fuchs (61), and he ascribes it to the fact that they live in crowded houses and are uncleanly. About glaucoma, the same ophthalmologist says that "among Jews inflammatory glaucoma is more frequent than among Christians" (62).

Of the many other diseases considered to be more common among Jews than non-Jews we will not speak here, because the writers who have described these peculiarities either have not substantiated their statements with facts, or their evidence is inadequate and is not borne out by experience among the Jews.

The causes of the peculiarities of the comparative pathology of the Jews have at different times received different interpretations. Some have attributed the fact that the Jews have a longer duration of life, a lower mortality, etc., and also their greater liability to be affected with nervous diseases than non-Jews, to indolence of the Jew, to his lack of exercise, to the rich, highly-seasoned food that the Jews are supposed to eat. Some have even gone so far as to say that the Jews consume very much sweets, and that on this account they are more liable to diabetes than Christians. That "the Jews are obliged to keep two Sundays in a week, besides Jewish, Christian, and political holidays, or two out of every seven days being lost to business, gives them, by necessity, about twice as many days of leisure as Christians" (63), is another argument. But all these reasons do not hold good at present, particularly with our American Jews, as almost everybody who comes in contact with modern Jews will testify.

Others have tried to explain the comparative pathology of the Jews as consisting of "biostatic" differences of the physiological organization of the Jews as compared with non-Jews. But there are no proofs that the Jews possess peculiar racial characteristics of a purely physiological or anatomical nature. The so-called "biostatic" differences of the Jews can be easily explained by their past history; the differences in customs in relation to the customs of non-Jews; to the devotion of the Jews as husbands, as wives, and as parents—to the family spirit of the Jews, the *sentiment de la famille*, as M. Legoyt calls it, which is more developed in them than in Christians, and which assures to their children, to their aged and infirm parents, a solicitude more active, to the newborn the mother's breast, to the poor and afflicted a more efficacious assistance. As a result of the pure, chaste, married life which the majority of the Jews lead, we find that alcoholism and syphilis are very rare among

them, and, with this, a number of diseases the ætiology of which in a great measure depends on these two virulent poisons, as nephritis, arteriosclerosis, tabes, etc. The result is that the Jew has that "unprecedented tenacity of life" which the above statistics have proved.

The custom of ritual circumcision practised by the Jews on every new-born male infant has been given by many authors (67) as a cause for the longevity of the Jews and their comparative immunity to certain diseases. Others have attributed the tenacity of life of the Jews to their excellent system of meat inspection, by which all those animals that are found to be suffering from disease, particularly pulmonary affections, are not allowed to be consumed by the Jews. Circumcision has probably a great deal to do with the fact that syphilis is uncommon among the Jews; it has hardly any influence on their susceptibility to gonorrhœa, excepting, of course, some of its complications, as balanitis, phimosis, and paraphimosis, which are unknown among Jews. But, excepting syphilis, in the opinion of the writer, circumcision has no influence whatever on the comparative pathology of the Jews. The "Kosher" meat, which the Jews almost invariably eat, may be a factor in the infrequency of tuberculosis among them, but outside of this we do not think that it prolongs their lives.

The past history of the Jew explains to us the reason why he has such a wretched aspect. Persecuted and abused for two thousand years, the Jew of to-day has comparatively less physical strength and muscular power, his blood is more diluted, his stature smaller, his chest and shoulders narrower, than those of his non-Jewish neighbors. But notwithstanding all these physical infirmities, the Jew resists misfortune, disease, and even death, as we have seen above, better than almost any other race. The reason for this apparent contradiction is not far to seek: the modern Jew is, physically and mentally, a product of natural selection, of a process of survival of the fittest which has been going on for two thousand years.

Being persecuted, oppressed, and tormented for centuries, only those who were the most stubborn, the most callous, the most energetic, could venture to remain Jews. All those who were too weak, sickly, and infirm, bodily and spiritually, were eliminated from the race either by death or baptism. The modern Jews are, therefore, possessed of a great "tenacity of life."

Another important point in the comparative pathology of the Jews is the fact that they are predisposed, in such a high degree, to the diseases of modern life—to hysteria, neurasthenia, most of the functional neuroses, and diabetes, as we have seen in the course of this paper. The Jew has been for centuries an urban resident, only rarely living in the country and engaged in agricultural pursuits. The diseases of the city population are therefore accentuated on his body and mind. We know that with the majority of the Gentiles the case is different. It has been shown by Mr. Cantlie, in his book *Degenera-*

tion amongst Londoners, that the London poor do not survive beyond three, or at most four, generations; the same has been proved to be the fate of the poor inhabitants of Paris. It is, indeed, rare to find among the poor in modern large cities families which could trace their ancestors back for five or six generations as city dwellers. The population of the cities is kept up by the constant influx of good, pure, fresh blood from the country, which counteracts the deteriorating influences of the busy, enervating city life.

The Jews have not had this advantage, and all the evil effects of the strained, nerve-shattering city life have consequently been transmitted to their offspring. With each new generation the nervous vitality of the Jewish race has lessened, and, as a result, we find that most of the diseases that increase with the advance of civilization, particularly the neuroses and psychoses, are relatively more frequent among the Jews than non-Jews.

"The Jew," says Leroy-Beaulieu, "is the most nervous, and, in so far, the most modern of men. He is by the very nature of his diseases the forerunner, as it were, of his contemporaries, preceding them on that perilous path upon which society is urged by the excesses of its intellectual and emotional life, and by the increasing spur of competition. The noisy army of psychopathies and neuropathies is gaining so many recruits among us that it will not take the Christians long to catch up with the Jews in this respect. Here, again, there are no ethnic forces in operation" (64).

The frequency of diabetes among the Jews is another confirmation of this contention. Diabetes is very much on the increase in all civilized countries, particularly in large cities. Some are even inclined to place it on the list of diseases of modern life. The Jews, as we have just shown, being hard sufferers of most of the diseases of modern life, could, of course, not escape it. The relation of diabetes to lesions of the nervous system has long since been observed, particularly by Claude Bernard. The Jews suffering very much from nervous diseases, are, therefore, to a large extent liable to diabetes.

As has been shown recently by Dickinson (65), the most common variety of diabetes is associated with diseases of the nervous system; pancreatic diabetes is uncommon. "Grief, anxiety, terror, may all be followed by diabetes so closely that there is no room for doubt as to their having occasioned it. * * * It is well known as a result of commercial disaster, and it may be said truly that every panic on the Stock Exchange produces its results in diabetes. It has recently come to light that engine drivers are especially subject to this disease, presumably from the anxious nature of their occupation." Diabetes is twice as common among engine drivers as in the ordinary population.

According to competent observers in England and America, Dr. Dickinson further points out some cases of insanity are accompanied by diabetes, and, while the pathology of both remains largely a problem for the

future, the association between the two conditions seems conclusive to Dickinson. This view of diabetes explains best the reason why the Jews are such great sufferers from this condition; being the most nervous of the European and American races, they show the largest percentage of insanity in their ranks, and they consequently have the largest proportion of diabetics in their midst.

Before we dismiss the subject, we want to state that it has been observed in Europe that the tenacity of life of the Jew and his resistance to certain diseases, as tuberculosis, syphilis, alcoholism, etc., diminish gradually as we proceed from east to west, from the countries where the Jew lives isolated, pursuing his life in his own fashion, adhering to the customs of his forefathers, to those countries where the Jew commingles and assimilates with the non-Jewish inhabitants, adopting their modes of life and habits. This has also been observed to be the case in the United States. Thus Dr. Billings has pointed out that "those (Jewish) mothers who were born in the United States average only 3.56 children each, as against 5.24 for those born in Germany, 5.63 for those born in Russia and Poland, 5.27 for those born in Hungary, and 5.44 for those born in Bohemia, indicating a diminished fertility in those women born in this country" (66).

In another place Dr. Billings shows that "the death rate among the Jews in this country is decidedly increasing," and that "the death rate among the native-born (Jews) of native-born parents was 9.16, and among the foreign-born 7.61."

It has also been observed by physicians that syphilis and alcoholism are decidedly increasing among those Jews living, for a longer or shorter time, in the United States. If this is actually the case, then we may expect that all those "biostatic" or "ethnic" differences of the American Jews will soon disappear.

SUMMARY.

I. The death rates of the Jews, at all ages, are relatively and absolutely lower than those of the people among whom they live.

II. The marriage rates and birth rates of the Jews are smaller than those of the Christians; the Jews increase in number more rapidly than non-Jews, because they lose by death relatively fewer children and bring more to maturity.

III. The Jews die less often than their neighbors from many of the infectious diseases, particularly epidemic cholera, small-pox, and tuberculosis.

IV. Syphilis and alcoholism, and also diseases due in great measure to their poisons, are comparatively rare among the Jews.

V. Diabetes is very frequent among the Jews. Most

observers have recorded that almost twenty-five per cent. of all the cases of diabetes occur in Jews.

VI. All the functional neuroses and psychoses, particularly neurasthenia and hysteria, occur more frequently among Jews than among non-Jews; while all the organic nervous diseases, as tabes, general paralysis, etc., are less frequent, commensurate with the infrequency of syphilis and alcoholism, among them. The great majority of cases of amaurotic idiocy occur in Jewish children, and insanity is met with among Jews between two and five times more often than among Christians.

VII. Blindness, colorblindness, trachoma and glaucoma, and also varicose veins, particularly hæmorrhoids and hernias, are very frequent among Jews.

VIII. All these peculiarities in the comparative pathology of the Jews are not due to any ethnic, "biostatic," or racial characteristics of a purely anatomical or physiological nature in relation to non-Jews. They have their origin in the past history of the Jews, in their habits of life, and in the fact that syphilis and alcoholism have but rarely been seen among them.

IX. Where the Jew is commingling with his Christian neighbors and adopts their customs and habits of life, he sooner or later loses his "racial characteristics," and his comparative pathology presents no special peculiarities.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

By NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

VISITING SURGEON, POST-GRADUATE HOSPITAL.

(Continued from page 537.)

DISEASES OF THE PLACENTA.—Before proceeding to consider the various morbid conditions of the placenta, it will be well to have a clear understanding of its formation and relation to surrounding structures. The placenta was so called by Fallopius because of its fancied resemblance to a flattened cake. When mature, it measures from six to eight inches in diameter and about an inch and a half in thickness. It is thickest at the centre and gradually becomes thinner toward the circumference. It subserves the double function of circulation and respiration. By means of it oxygen and nourishment are brought for the development of the fœtus, and carbonic acid and other effete materials are given off. The placenta is, therefore, a medium of intimate communication between the fœtus and the mother. The development of the placenta takes place in the third month of pregnancy. Previously to that period the ovum receives its nourishment from the umbilical vesicle and the allantois. The placenta has not an independent origin, but is gradually evolved from the decidua and the chorion; the part of the decidua concerned in its formation corresponds to the part to which the ovum becomes attached, and is called the serotina. (See Fig. 3.) Toward the end of the second month the foetal elements of the placenta are composed of innumerable small cotyledons projecting out from the walls of the ovum. These

gradually increase in size, and eventually develop into fully formed chorionic villi. They are not of uniform size, and they branch off at irregular angles. (See Figs. 4 and 5.) Their distal ends become somewhat club-

villi are preparing for the important function they are to assume when fully developed, many mishaps may occur. After the third month of uterogestation, the various morbid conditions of which the uterus is composed are considerably firmer and deviations are not nearly so prone to take place.

To one who has investigated the subject of diseases of the placenta it soon becomes apparent that authors have heretofore been much divided in opinion as to the various morbid conditions that may affect this organ. Under different appellations they have described progressive stages of the same disease, and in various other ways have jumbled the pathology of this important structure in a skein of inextricable confusion. Many of them seem to regard the particular diseases they have had the opportunity of witnessing as the most important with which the placenta is affected. This is altogether too narrow a view of the subject. We can see no reason why the placenta cannot be affected by as many pathological conditions as the brain, liver, or lungs. In attempting to lay before my readers the most important affections of the placenta that may be considered detrimental to the well-being of the foetus, I do so with a feeling of consciousness that my task will be imperfectly performed, but, nevertheless, with a knowledge that the subject abounds in many more morbid conditions than is generally believed.

Placental Hæmorrhage.—From what has been stated in previous paragraphs, it is but natural to suppose that apoplexy of the placenta, with the various morbid changes following as a consequence, may be considered one of the most frequent pathological conditions of the

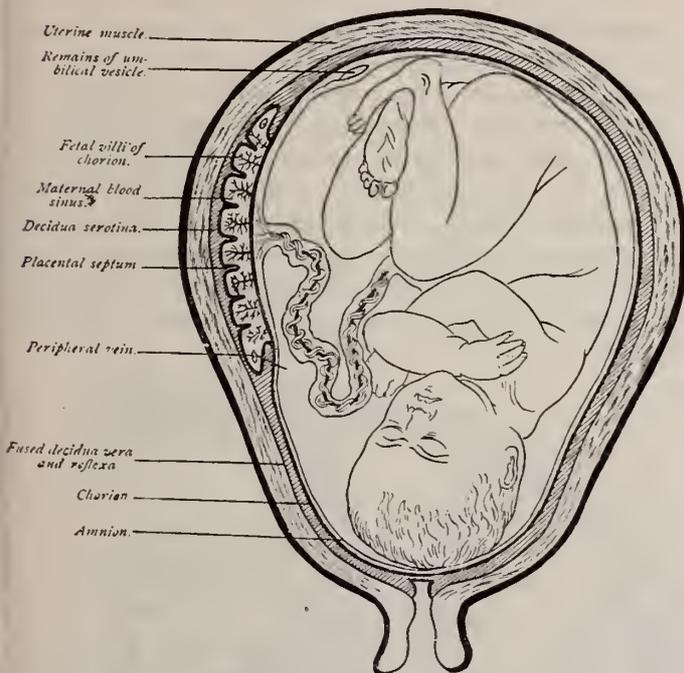

FIG. 3.—Semi-diagrammatic section of uterus, showing relation of foetal and maternal placenta (Ahlfeld).

shaped and, at the point of attachment, they are constricted. Coursing over these projections are innumerable small blood-vessels from the allantoic arteries and veins. They are so numerous that they form vascular tufts on the surface of the villi. The maternal portion of the placenta, as already indicated, is derived from the decidua. The blood-vessels of the uterus become very large at the particular part that goes to form the placenta, and are then called sinuses. The small projections from the chorion dip into these sinuses and are continually bathed in maternal blood. It is in this way that the foetus receives its necessary nourishment for growth and development. During the time the foetus has its abode in the uterus, the aeration, or decarbonization, of its blood is effected in the placenta. The impure blood of the foetus is brought to the placenta by the umbilical arteries. These communicate directly with the umbilical veins in the placenta, but have no direct continuation of canal with the maternal circulation. The mother and foetus have entirely distinct and independent circulations. These, however, lie so closely together in the placenta that they may be said to be in juxtaposition and to interdigitate. The carbonic acid of the foetus is liberated from the umbilical arteries and receives in return the necessary amount of oxygen by an endosmotic action. The parent, besides supplying the oxygen to the foetus, transmits, by a process of percolation, the necessary amount of nourishment for the development of the foetus. It is quite natural to suppose that, during the period in which the

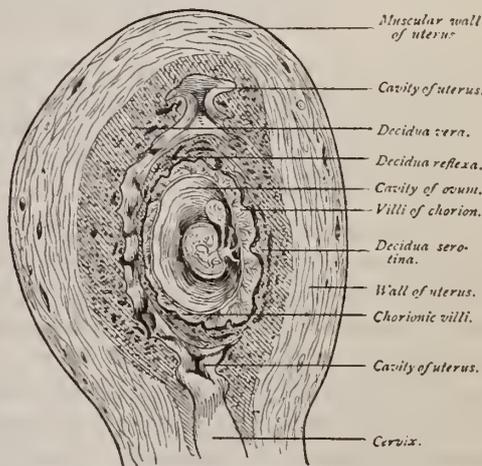

FIG. 4.—Semi-diagrammatic section of gravid uterus, showing the ovum at five weeks (Allan Thomson).

placenta. During the early months of pregnancy, when the placenta is in the course of formation, the opportunities for deviation from normal progress are extremely frequent. When one contemplates the many subtle influences that Nature adopts to correlate and adjust the blood supply to the necessary fulfilment of her purposes, it is marvelous how frequently she accomplishes her designs so satisfactorily. Up to the end

of the third month the placenta may be said to be in a rudimentary form. Its sinuses and cavities are not yet elaborated. Permeating everywhere over the surface of the villi, miniature loops of blood-vessels are weaving intricate webs so tender and fragile that many of them cannot be seen by the naked eye. It is not to be wondered at that extravasations of blood from these loops are exceedingly common. Such effusions may be due to local conditions, although they frequently arise from constitutional causes, as we shall see directly. If such extravasations are limited in extent, little or no damage may arise. When, however, they embrace a large surface, the nutrition of the embryo becomes impaired, if, indeed, the whole ovum is not entirely expelled. When such a hæmorrhage occurs, the ovum not only loses the

ment is not yet very intimate. The clot then is most frequently found in the substance of the placenta, although it is sometimes found between the uterine walls and the maternal surface of the placenta. There is this difference between hæmorrhage in the early period of gestation and that resulting when the placenta is fully organized, that, in the latter, larger effusions of blood may take place without interfering with the progress of pregnancy. So it happens that, the larger the size of the placenta the less risk there is to the safety of the child, so far as hæmorrhage and its consequences are concerned. There remains still another reason why hæmorrhage in the early stages of uterogestation is followed by more serious results. During this period the villi of the chorion are extremely fragile and but slightly

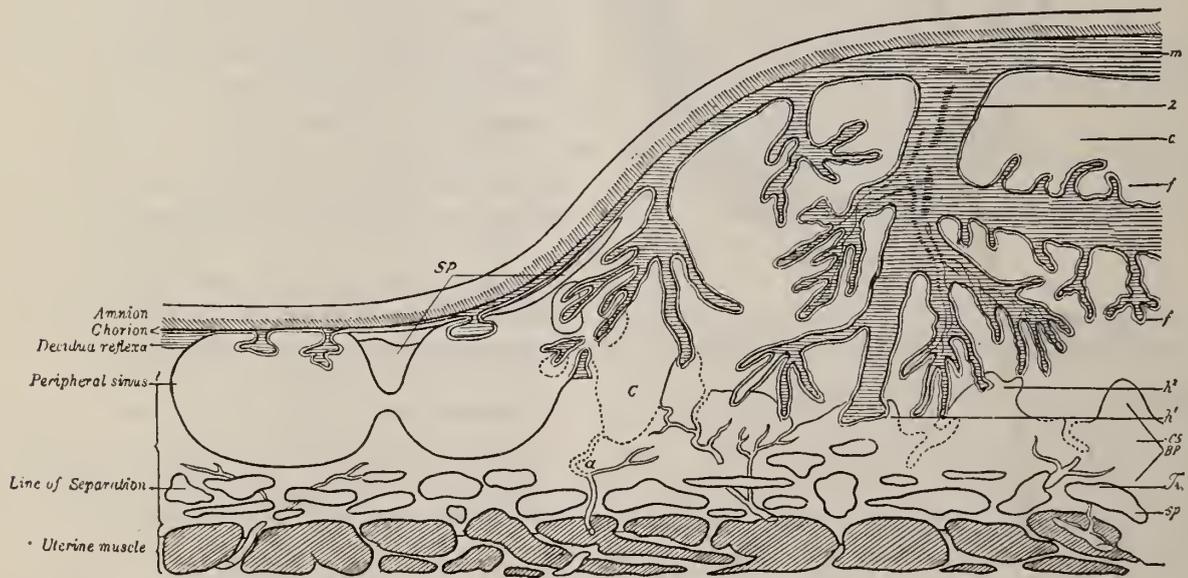

FIG. 5.—Diagrammatic section through the human placenta at the middle of the fifth month (after Leopold). The foetal placenta, consisting of the chorion (*m*) with its villi (*z*), has grown into the maternal placenta; the villi present attached points (*h*¹, *h*²) and free processes (*if*); *sp* is the spongy layer of the decidua serotina, in which the separation takes place along the line *Tr*; *CS* is the compact layer forming the inner part of the uterine placenta, which consists of the basal plate (*BP*) the closing plate (*SP*), the arteries (*a*), the cavernous blood-spaces (*c*), and the marginal sinus.

nourishment from the ruptured vessels, but the resultant clot compresses the root-like projections of the surrounding villi, and thereby so crushes their blood-vessels as to render them entirely useless. All sizes of clots and shades of color may be found. When recent, the clots are of a red color and disorganized. Those that have existed for some time will be found to be consolidated, indurated, and of a brownish appearance. The villi have become atrophied, and so blended together in one mass that it becomes difficult to recognize them. The situation of these clots depends largely upon the period of rupture. Until after the period of three months of uterogestation the various membranes are separate, but no space remains between them. Hæmorrhage taking place previously to this time may be found burrowing down between any of them. After the third month, the various membranes come into apposition and there is not an interspace between them, although the attach-

embedded into the substance of the decidua serotina. There is a general laxity and insecurity of these structures, and hæmorrhage with extravasation is much more liable to occur than when, afterward, they become mature and firm and more able to resist. When the uteroplacental sinuses are fully formed and the villi are mature and project into these lacunæ, there is no doubt that many extravasations of blood are caused by a thrombosis in these sinuses. The maternal blood circulates very slowly through these lacunæ and eddies about for a considerable time before it passes away in the maternal veins. Anything that interferes with the free flow of this circulation will of necessity cause a certain amount of stagnation and coagulation. The blood of pregnant women being richer in fibrin than normally renders coagulation in these sinuses easily possible. Any sudden or gradual slowing of the maternal circulation may be followed, therefore, by the formation of a throm-

bosis. Weak, delicate, and nervous women are susceptible to fainting spells and syncope, the pulsations of the heart become greatly diminished, there is an arrest of the circulation in the uteroplacental sinuses, and thrombosis may quickly follow.

There is good reason for believing that there are frequent coincidences between the occurrence of extravasations into the substance of the placenta and of hæmorrhages in other organs of the body. Valvular disease of the heart, Bright's disease, interference with the portal circulation, syphilis, calcareous deposits in the placenta—each and all tend to passive congestion, and eventually to a weakening of the coats of the blood-vessels. It is to be remembered that hæmatophiliacs and anæmic women are singularly liable to such hæmorrhages. Given any one, or a combination, of these constitutional tendencies, it can be readily understood that it does not require much of a local injury to bring about a hæmorrhage. The direct causes may be numerous, and sometimes difficult, to locate. Some unusual exertion, such as a false step, jerk, fall, or blow, can generally be traced as the exciting cause. In the great majority of instances there is a previous degeneration of structure from some of the diseases just enumerated. Especially is this so after pregnancy has advanced beyond the third month. The results of such hæmorrhages vary widely. Sometimes the amount of injury is limited, and little or no damage is inflicted upon the fœtus. But a larger area may be involved. The clot then may tear through uteroplacental sinuses, separate the membranes from the uterine wall, and burrow on down to the *os uteri* and into the vagina. There may be little or no pain associated with this accident, and generally the first indication made manifest to the patient is the sudden and unexpected appearance of flooding from the genital passages. In a certain number of cases, the extravasated clot may remain at the point of rupture. The amount may be large or small, according to the number of uteroplacental sinuses ruptured and the integrity of the surrounding structures. When extensive, the product sometimes bulges the uterine wall so considerably outward as to be felt, through abdominal examination, as a nodular mass. This constitutes the condition described in our text-books as "concealed hæmorrhage." If the amount is reasonably small, it usually remains localized at the area of formation and does not interfere with the progress of pregnancy or the integrity of the fœtus. Whatever their size, these clots seldom entirely disappear, but go through various phases of changes peculiar to retained clots in any other part of the body. Their fibrin frequently becomes lardaceous and then breaks up into two varieties of granulations. The first is of a proteid character, soluble in acetic acid and alkaline fluids; the other is not soluble in these agents, and is of a fatty nature.

Placenta Prævia.—A variety of hæmorrhage different from any we have hitherto mentioned is that which

results as a consequence of a misplaced placenta. It is an exceedingly dangerous complication, both to the mother and the child. Fortunately, in recent years the profession has been enabled to meet the emergency in a more scientific and rational method than was done formerly, and much of the danger has been thereby obviated. The ætiology of this condition has for a long time remained a fruitful theme for discussion. Long ago the subject was considered a serious one by the ancients. They did not, however, understand the causes of this anomaly, and the treatment was unsatisfactory. We cannot boast much of our superior knowledge of its pathology. There are several interesting speculations as to why a placenta becomes attached to the lower segment of the uterine cavity instead of to the fundus, where it normally belongs, but no one has yet produced a theory that has not many objections.

Dr. Tyler Smith maintained that the ovum, in these cases, was not impregnated in the tube, but in the lower portion of the uterine cavity in the neighborhood of the *os uteri*. His syllogism is obviously defective, although there may be a certain amount of accidental truth in his theory. His premises depend on the belief that impregnation normally takes place in the Fallopian tube, and not in the uterine cavity. With these teachings we cannot agree, for reasons already given. Müller and others have advocated the theory that the impregnated ovum originally became attached to the fundus, but that, from uterine contractions or accident, it soon became detached and dropped to the lower part of the uterus. Here it again became adherent and began to develop. These and other theories are devoid of substantial regard because of their incompleteness. If the physiology of the endometrium had been as well understood by these writers as it is at the present time, it is quite probable that they would have advocated a more plausible explanation as to why such ova occasionally become attached to the lower part of the uterus. Before a placenta prævia can possibly occur, it would seem to be a self-evident proposition that there must be a preexisting defect, either congenital or acquired, in some part of the mucous membrane of the uterus. More frequently this is acquired. Just why Nature, in her own subtle, clever ways, chooses the fundus for the implantation of the placenta is not definitely determined. The explanation of many of these things is frequently difficult of accomplishment. There is this to be stated, however, that all the important viscera are suspended, and not supported from below; and so it is with the fœtus. It is safer for the fœtus to be suspended from the dome of the uterus than it is for it to be carried in the lower segment of the cavity. In the former case, it is comparatively free from vibrations, shocks, and accidents. It has already been stated that the mucous membrane of the uterus has a certain amount of preparation to undergo before its surface is in a suitable condition for the retention of a fertilized ovum. Like many other per-

versions in and about the uterus, this preparation may be defective in physiological precision. The nervous mechanism regulating this function sometimes becomes disarranged for some unknown and inexplicable reason.

Formerly it was believed and taught in text-books that the whole of the mucous membrane was cast off at each menstrual period, but recent investigations have demonstrated the fallacy of this teaching. This mucous membrane is covered by columnar ciliated epithelium. Once a month, by a process of denudation, this epithelium is shed. The most important essential in the cycle of menstruation is the shedding of this epithelium. We have long maintained that it is absolutely impossible for a vitalized ovum to become attached to an epithelial surface. In normal menstruation, the latent cells and capillaries of the mucous membrane are thrown into periodic activity, the epithelial covering is exfoliated, and the underlying surface becomes engorged and swollen, and ready for an ovum to become embedded into its soft, velvety wall. Occasionally it happens that the whole of the superficies does not participate in the functional activity. Menstruation then may be imperfectly accomplished. It is possible for part of the epithelial covering to remain adherent to the mucous surface. When this takes place in the fundus, it would be quite impossible for a fertilized ovum to become attached. The result would be that it would be forced down the side of the uterine wall, and, when it reached a suitable surface there, would become embedded.

Chronic endometritis is another pathological condition that may directly cause a placenta prævia. The area in the region of the fundus may be so affected that an ovum cannot become adherent. The lower segment, at the same time, can be in a sufficiently healthy state to offer a resting place for its attachment, and there it may develop.

However caused, the condition is an exceedingly dangerous one, and may suddenly place the life of the mother or child in imminent jeopardy. The earliest symptom manifest is more or less sudden hæmorrhage, without any assignable reason. It is seldom that this comes on before the sixth month, and sometimes not until the beginning of labor. Unlike other varieties of hæmorrhage from a pregnant uterus, once it has begun, the natural tendency is for frequent repetitions. It is almost universally admitted that the source of the hæmorrhage is from the uteroplacental sinuses. It is not yet definitely determined how this is brought about. Until recently, and even at the present time, it is supposed by many to depend upon the gradual expansion of the lower part of the uterus during the later months of pregnancy. This probably is not a correct explanation of placental separation, for the expansion of the lower part of the uterus during this time is more apparent than real. Another theory, somewhat similar to this, was first advocated by Jacquemier. It is to the effect

that, during the first six months of pregnancy, the fundus develops to a greater proportion than does the lower segment; that at six months the superior portion has attained its maximum growth, and that, consequently, the cervical part attains its principal expansion during the three last months. This theory cannot be accepted, for there is not convincing evidence to show that one portion expands in greater proportion at any period than another. Matthews Duncan maintained that the hæmorrhage associated with placenta prævia previously to the onset of labor was purely accidental. In all, he advanced the following reasons for its occurrence:

1. The rupture of a uteroplacental vessel at or about the internal *os uteri*.

2. The rupture of a marginal uteroplacental sinus within the area of spontaneous premature detachment, when the placenta is inserted, not centrally or covering the internal *os*, but with a margin at or near the internal *os*.

3. Partial separation of the placenta from accidental causes, such as a jerk or fall.

4. A partial separation of the placenta, the consequence of uterine pains, producing a small amount of dilatation of the internal *os*. Such cases may be otherwise described as instances of beginning miscarriage arrested at a very early stage.

I coincide with these opinions, with a modification. The objection entertained is that he advances or hazards no reasons why such separations take place more frequently when the placenta happens to be implanted in the lower segment of the uterus.

It may seem bold and reckless to break away from the teachings of the many distinguished men who have written upon this subject; nevertheless, I have long entertained the opinion that one of the cardinal reasons for the hæmorrhage accompanying placenta prævia previously to the onset of normal labor has been entirely overlooked. From the time a fertilized ovum begins to develop in the uterus until the full period of gestation the uterine walls have a rhythmic action of alternate contraction and relaxation constantly in progress. At first they are very weak, but as the uterus develops these contractions become correspondingly firm. In the later months of pregnancy they are quite powerful and can readily be recognized by placing the palms of the hands over the uterus for a few minutes. Labor pains are but exaggerations of these rhythmical contractions. Occasionally it happens that these contractions incessantly at work are more powerful than the necessities of Nature demand. These contractions have more influence upon the lower part of the uterus than they have toward the fundus. I advance the proposition, therefore, that the lower the placenta is implanted, the greater becomes the danger of accidental laceration of a uteroplacental sinus. These contractions begin at the fundus and increase in volume and strength as they

approach the cervix. When the placenta is implanted in the fundus, these contractions have not yet accumulated sufficient force to affect its uteroplacental sinuses injuriously. The climax of such contractions strikes the lower part of the uterus only. When, therefore, a placenta happens to be located in this locality, it receives the full power of these incessant contractions and is very liable to be severed from its attachments. Add to this jerks, falls, and blows, and the fact that the placenta is situated beneath the child, where its weight comes down with full impact against the placenta, and the causes for such hæmorrhages become reasonable. There may be contributory causes, such as a normal weakness of attachment, but I maintain the reasons herein given to be the main causes for the frequent floodings following in the wake of placenta prævia.

Placentitis.—Inflammation of the placenta is not a frequent disease. It does occur, however, and, if extensive, is generally fatal to the life of the foetus. It is characterized by the usual phenomena of inflammation in any other part of the body. In the placenta, it is usually a chronic process. There will be, first, engorgement and more or less tortuosity of the blood-vessels; then, exudation of serum and organizable lymph or fibrous products. There is a striking similarity in appearance between inflammation of the placenta and hepatization of the lungs. This resemblance will correspond to the period in inflammation of the placenta when solidification of tissue has taken place as the result of exudation. The particular variety of inflammation that is most frequently encountered is the productive. It is exceedingly chronic in its action, and there appears to be a low order of vitality in the exudation thrown out. Frequently the mass of deposit crumbles down in the centre, and then hæmorrhages into the cavity may result. In appearance these masses of inflammatory product scattered throughout different parts of the parenchyma sometimes bear a close resemblance to tuberculous deposits. They are clearly not tuberculous, although many of the older writers described this disease under the appellation of placental phthisis. If the inflammatory action is limited, and the exudation that follows rapidly organizes into a fibrous deposit, it is possible that little damage may result. When, however, the area affected is at all extensive, the result will, in all probability, cripple the function of the placenta to such an extent as to imperil the safety of the child. The manner in which the injury is effected is not difficult to comprehend. When an exudation is thrown out as the result of inflammatory action, the placental villi are compressed and crushed together, and prevented from being bathed by the maternal blood in the uteroplacental sinuses. Should this exudation be of low organization, softening and caseation will shortly take place. If the product undergoes fibroid transformation instead, contraction of the villi will take place, the circulation through them will eventually be cut off, and

the cavernous structures entirely filled up with an inert mass. It depends altogether upon the area involved as to whether the child will perish. If the inflammatory product is limited, there may not be sufficient damage to seriously affect nutrition. Nearly every obstetrician who has had extensive experience in this branch of the profession has encountered the effects of inflammatory changes in the placenta. There may be indurated nodular masses throughout the parenchymatous substance of the gland, or patches of broken-down tissue. The condition is one that may cause placental retention after normal delivery. Adhesions form between the placenta and the uterine walls, and it may be extremely difficult wholly to liberate the afterbirth. Again, the inflammatory action may have left the placenta in such a friable condition that moderate traction on the umbilical cord, or even uterine contraction, may be sufficient to cause a solution of continuity, and part of the placenta may be left adherent to the uterine walls. Such surfaces remain a constant source of danger from infection. The great majority of cases of placentitis are chronic, but, occasionally, there appears evidence that would indicate the process to be a more or less rapid one. This is inferred from the fact that, in exceptional instances, a plump, fat, and well-developed dead child is born, with a placenta engorged and infiltrated with recent exudation. The placenta has suddenly become choked and intra-uterine respiration can no longer be maintained. It is, in fact, an acute "pneumonia" of the placenta. It is extremely difficult to trace back the causes that produce this condition. Frequently a tuberculous or syphilitic history can be established, but as often not. That anæmia is frequently associated with placentitis is beyond dispute. In pregnancy there is a deficiency of red blood corpuscles and an excess of fibrin. These conditions may tend to a lower form of inflammation of the placenta.

It is difficult to make efficient injections into placenta that are diseased as the result of an inflammatory process. This interferes seriously in making microscopic researches. The injections can, of course, be forced through the healthy structures, but the parts matted together it is impossible to enter. It becomes necessary, therefore, to resort to thin sections and to staining. Microscopic examination of inflammatory deposits shows beginning retrograde metamorphosis in the diseased parts; the deposit beginning to form connective tissue and the round corpuscles assuming an elongated form. Evidence of beginning fatty degeneration can sometimes be seen. In recent deposits, where disorganization has not entirely destroyed the integrity of the blood-vessels, there is great hypertrophy of the muscular coats. This may be due to a compensatory effort upon their part to overcome the obstruction that has already taken place in the extremities of the villi. It may be considered analogous to that which takes place in certain diseases of the kidneys.

(To be continued.)

RECTAL FEEDING IN THROAT DISEASES.

By A. C. BARDES, M. D.,

NEW YORK,

INSTRUCTOR IN DISEASES OF THE NOSE AND THROAT, NEW YORK
POLYCLINIC; ASSISTANT SURGEON, NEW YORK EYE AND
EAR INFIRMARY (DEPARTMENT OF THE THROAT).

BEFORE I became interested in this subject, I was often impressed with the thought that, if a diseased throat could be given absolute rest, it would recover in a shorter time than it would without the rest. Whenever any part of the body is diseased, in order that the patient may be comfortable, and before the process of repair can go on uninterruptedly, the diseased member must be at rest and free from irritation. The splint is applied to the fracture and the bandage to the wound for the purpose of giving rest to the diseased part, and this should also be our object in treating diseased conditions of the throat. A person with a diseased throat knows from experience that the less the part is disturbed the sooner it improves; and it is for this reason that a gargle, instead of relieving an inflamed throat, actually aggravates it. No one would advise rubbing an acutely inflamed joint; it is given rest. Then why should not the throat be treated in like manner?

The taking of food causes the throat sufferer more dread than anything else, for the food, in passing over the inflamed surface, together with the movements of the throat in swallowing, so intensifies the pain that people often prefer to go without food rather than suffer the distress from the effort to swallow; and thus, as they do not receive sufficient nourishment, the reparative process is retarded and the suffering is prolonged.

Very often an invalid with chronic pulmonary tuberculosis is able to live for months, and even years, in comparative comfort, provided the digestive organs are in a healthy state and enough food is taken to nourish the patient and hold the disease in check. As soon, however, as the disease invades the throat and interferes with swallowing, the patient will take less nourishment, and thus the system becomes less able to resist the ravages of the disease, and there ensue loss of flesh and rapid decline. For such a person, rectal feeding is helpful in that enough food can be taken to enable him to regain strength, at the same time allowing the lesion in the throat to heal.

Nourishment and stimulation *per rectum* are applicable in all cases in which swallowing is difficult or painful, or in which an operation has been performed upon the throat and the wound is to be kept quiet. A person can be fed by the rectum solely for two or three weeks, and Flint mentions a woman who was wholly nourished by the rectum for five years. Feeding *per rectum* is of particular service in diphtheria, in tuberculosis of the throat, and after staphylopharyngitis, for here the throat is given rest, and the patient is spared the pain and dis-

tress that are incident to the taking of food in the natural way.

My attention was first called to the importance of rectal feeding in a case of diphtheria in which the child was attacked with septic pneumonia consequent on the entrance of food into the lungs. Often in diphtheria, and frequently in scarlet fever, the mucous membrane of the throat loses its acute sensibility, and food often gains access to the larynx without being expelled. This danger is avoided in rectal feeding. In this way the throat can be kept comparatively free from bacteria, and, there being no irritation, repair of the membrane is encouraged.

We all know how the little ones resist the taking of food and stimulants by the mouth; they often struggle until they are exhausted or overcome, their struggles resulting not infrequently in collapse, and, when the food finally is forced into the mouth, some of it frequently escapes into the nose, and a portion may even enter the larynx. Feel the pulse now, and the patient will be found very weak. In diphtheria the heart is not over-strong at any time, and undue exertion may be followed by heart failure. The food and liquor, the giving of which is so necessary in diphtheria, can be readily administered by the rectum, and the child's strength can be reserved to battle with the general infection; this satisfies the mother and her friends, who often object to the use of force.

An intubated child can be nourished in this manner for a week or two without the slightest discomfort, and one of the sources of danger to an intubated child, the entrance of food into the tube, is avoided. If food gets into the tube, it is apt to deprive the child of air or else cause a cough which may result in the expulsion of the tube. When a person is in a state of coma, it is with difficulty that food can be directed into the proper channel, or, again, the patient may be asleep and we do not wish to disturb him. Try artificial feeding.

In tuberculosis of the throat, particularly if there is ulceration, swallowing is often both painful and difficult, and unless this condition is relieved the patient will emaciate rapidly, for, notwithstanding the liberal use of cocaine, very little food is taken, and that which is eaten is not relished, for the cocaine removes the desire for food and retards its digestion, besides exerting a depressing effect upon the patient. Then, again, the food, as it passes over the ulcer, so irritates it that it counteracts any good that is accomplished by local treatment. There is also induced a reflex cough that is attended with vomiting and general distress, and even pulmonary hæmorrhage may be brought on by it.

Some years ago Dr. Delavan devised a soft-rubber tube for the feeding of patients with tuberculosis of the throat. The tube is passed into the œsophagus after the manner of a stomach tube. I have found that the tube causes so much distress that many patients prefer not to use it. In rectal feeding, however, we have a

means for the relief of these conditions, and, if it were more generally used, much of the suffering of tuberculous patients would be avoided.

A person suffering with a circumtonsillar abscess (quinsy), even after it has been incised, is often unable to swallow properly for a time, because the constrictor muscles are hampered in the performance of their function, so that food and drink, instead of being swallowed, will wholly or in part be forcibly ejected from the nose, causing additional distress and pain, thereby weakening the patient and delaying recovery. Here, also, rectal feeding will do much to assist recovery.

After the removal of tonsils or adenoids the throat is so sore for some time, and swallowing is so painful, that little or no food is taken, and the child becomes irritable. If, however, feeding is carried on by the rectum, the throat will get well in a shorter time, for the food keeps up the patient's strength, and rest to the throat insures freedom from irritation.

In cancer of the tongue or throat, swallowing is both painful and difficult, and the food irritates the growth and increases its activity. Rectal feeding is useful here; it gives rest to the throat and thus retards the progress of the disease, sparing the patient to his friends for a longer time than would otherwise be the case. After operations for cleft palate, it is essential that the flaps be kept quiet, so that they will unite readily, and this purpose is best served by rectal alimentation, giving the throat absolute rest. Syphilis of the throat, spasm of the larynx, œdema of the larynx, glossitis, and many other affections of the throat are greatly relieved if the throat is kept at rest. Many throat diseases are accompanied by trouble in another organ, and the progress of the disease in the remote organ is often dependent upon the condition in the throat, and, as the throat trouble is improved by rectal feeding, the associated trouble is also benefited. Phthisis, asthma, nephritis, and gastritis are types of these diseases.

The value of rectal feeding was known to the ancients, but, as it was thought that digestion could not go on in the rectum, it was but little used. Recently, however, it has been shown experimentally that food introduced into the rectum is almost wholly absorbed, and even partly digested, the colon vicariously doing the work of the small intestine.

A few examples of cases that have been under my care will serve to illustrate the importance of artificial feeding in throat diseases:

CASE I.—*Diphtheria*. I was called to see a child which had been ill with diphtheria for five days, and during this time it had become greatly emaciated. Swallowing was so painful that the little one resisted the taking of food with all the energy it could command, and its struggles were such that two attendants had to hold it before nourishment could be forced into its mouth, and after much straining and gagging some food was swallowed, although much of it escaped through the nose. Having witnessed the struggles of

the infant and having noted its exhausted condition after the ordeal, I directed that thereafter nourishment be given *per rectum*, which resulted in giving entire satisfaction to the mother and those interested, for the child appeared not the least disturbed when the enema was given. The pulse quickly responded to the stimulation, and the patient was soon in a refreshing sleep, from which it was not awakened when the next feeding took place.

From the beginning of the feedings the improvement was rapid, and this was due in great part, I believe, to permitting the child to rest, reserving the energy which had been used in resisting the forced feeding; then, again, the depression that accompanies diphtheria was in a measure neutralized. In this manner the infant was fed for six days, the only drink that it received during this period being an occasional sip of cold water; after six days of rectal feeding the patient made an uneventful recovery.

CASE II.—*Tuberculosis*. A man aged forty-five came to me with his throat and larynx affected with tuberculous ulcers. He dreaded above all things the taking of food, for it caused such intense suffering that often he would abstain from nourishment for twenty-four hours or more. He lost in weight about twenty pounds in ten days, which so debilitated him that his power of resistance was diminished and the disease rapidly progressed. Rectal feeding was advised, and at the same time a twenty-five-per-cent. solution of lactic acid was applied to the ulcers. After the first nutrient enema of brandy and milk, the patient felt better, and that same night he enjoyed a sound sleep for the first time in two weeks. Under this treatment, and after I had removed a portion of the epiglottis, I succeeded in healing the ulcers with applications of lactic acid.

The patient gained weight and strength steadily, and two months after he began treatment he was able to leave for the mountains. Recently he wrote to me stating that he was in better health than he had been for two years, and, although he is now able to swallow without much distress, he prefers to take a nutrient enema each night before going to bed, for he has found that his health declines when the injections are discontinued. With him, as with most people with tuberculosis, food taken into the stomach is not readily digested, and the resulting distress is quite annoying. With rectal feeding, however, the stomach is allowed rest and is thus enabled to return to its natural condition.

CASE III.—*Hay Fever and Asthma*. Miss S., a young lady of twenty-two, had had for five years an annual attack of hay fever. The trouble began in July and continued until September, lasting in all about two months. Each succeeding year the attacks had been more violent than in the preceding year, and the taking of food by the mouth had always intensified the suffering and brought on an attack of asthma.

An asthmatic attack following the taking of food is a condition that I have observed in other cases of hay fever; the cause appears to be reflex, the attacks coming on shortly after the food is eaten and lasting from a few minutes to an hour; the severity of the attack of asthma in these cases is commensurate with the amount of food eaten.

The lady referred to above, after suffering greatly for ten days, came to me for treatment. She was given the various remedies for hay fever that are usually em-

ployed, among them the suprarenal extract, the much-lauded remedy of specialists; but all to no purpose, for the attacks became more numerous and severe than before. Convinced that rest to the stomach would give her case, I directed that her food be given *per rectum*. Soon after the first enema the patient was relieved, and the improvement continued steadily, so that in a week after the first enema the hay fever had subsided considerably and the patient had had but three slight attacks of asthma.

Thus the patient was fed for two weeks, and after that time the enemata were supplemented by food guardedly taken by the mouth, until September 17th, when the enemata were discontinued, the patient having now entirely regained her health.

As so little is taught on rectal feeding in the medical schools, and as the success of the treatment depends largely on carrying out the minute details, the manner in which the nutrient enemata are prepared and the mode of administration may be of interest, and this I shall endeavor to set forth in as simple a manner as possible. Before administering the nutritive enema, a cleansing injection of a quart of water and a teaspoonful of salt will evacuate the bowel sufficiently, and an hour later the first rectal feeding can be given. The cleansing enema, besides preparing the bowel for the reception of the food, produces a free movement of the bowels, which in itself is most desirable, for it relieves the tension of the congested vessels in the throat as nothing else will do.

The quantity of food administered with each injection should range from one to six ounces, according to the age of the patient, and the enemata should not be given oftener than once in three or four hours. Although the bowel is capable of some digestion and of the absorption of most of the food products, it is best that nutritive enemata be composed of predigested or peptonized food, for these are preeminently adapted for rectal feeding because of their remarkable diffusibility. The composition of the enemata should be altered occasionally, so as to obtain the effects of the absorption of a variety of the food products. When the rectum is irritable, from two to ten drops of laudanum or about fifteen grains of corn starch may be added to the enema. When the administration of a stimulant is required, whiskey or brandy may be incorporated with the enema, in quantity ranging from ten drops to half an ounce.

The mode of introducing an enema is as follows: Place the patient upon the side, with the knees flexed so as to relax the muscles of the thighs. Introduce a soft rectal tube or a No. 12 male catheter into the rectum for five or seven inches; attach to the end of this tube a piston syringe, and inject slowly into the rectum the previously warmed nutrient fluid; then slowly withdraw the tube and allow the patient to lie quietly upon the side for fifteen minutes or so, or until all desire to evacuate the rectum has passed.

Concerning the composition of nutrient enemata, milk is the article most generally used; it is readily absorbed, and its use is not apt to be followed by irrita-

tion. The carbohydrates are likewise readily absorbed, experiment having shown that from thirty to ninety-five per cent. of these articles of food are absorbed in a few hours. Enemata are prepared by the cold process and by the warm. The former is suitable when the injection can be retained; otherwise the warm process should be used. The cold process of preparing food is as follows: Dissolve about ten grains of pepsin in four ounces of water, add a pint of milk, and then put it on ice. When needed, heat to 105° F. and inject. In the warm process, the food is prepared as above, and then heated to 115° F. for half an hour; then it is placed on ice until needed, when it is again heated to 105° F. before being injected. An egg, well beaten, is an acceptable addition to this enema.

It is well to remember that the temperature for peptonizing is 115° F. and the temperature for injecting is 105° F.

Whey is an agreeable food for rectal alimentation. It is prepared as follows: To half a pint of milk heated to 115° F. add a teaspoonful of essence of pepsin; let it stand for five minutes, and then stir until the curd is separated; then strain and warm the whey and inject it without diluting. Other nourishing enemata may be made from various food preparations.

To sum up, some of the advantages alleged for rectal feeding are as follows:

1. The throat, being at rest, is not irritated.
2. Struggling in children is obviated.
3. The progress of the disease is shortened.
4. There is no danger of food entering the larynx.
5. The physician is able to give such food and stimulation as he wishes to give.
6. The food is not bolted, as it is when swallowing is painful.

317 EAST THIRTEENTH STREET.

THE MEDICAL ASPECT OF CHRISTIAN SCIENCE.*

By W. M. POLK, M. D.,

NEW YORK,

DEAN OF THE MEDICAL DEPARTMENT, CORNELL UNIVERSITY.

MY purpose is to deal with the medical, as distinct from the religious, aspect of what is called "Christian Science." You know, of course, that "Christian Science" is only one of several forms of so-called "mind cure" which have from time to time appeared, and which of late have been especially active; and, I suppose, your reason for selecting this form is because of its special claim to being in itself a revival of the method of cure employed by our Savior, and by Him enjoined upon his disciples as a part of their earthly mission, thus giving it a claim to attention from you as being of those disciples.

*A paper read before the Church Congress, November 13, 1900.

Speaking, then, for my profession, Medicine, I rejoice at this action; not that we need your help in dealing with our side of this particular "ism," but rather we rejoice that you seek the cooperation of the science of medicine, even semi-officially, in determining such questions as this; a course which, had it been pursued more openly and liberally in the past, would have been of immense service to us, and, we believe, of no detriment to you. I accept it as a harbinger of a time when religious bodies will cease to be the endorsers of our charlatanries. Turning to our question, however, we find that, so far from being new, it is older than Christianity itself; just as old as the recognition of the fact that man had a spiritual and a material side to his make-up. For all time, down to the present, our ailments have been, and will continue to be, dealt with from both sides, for, even at the present, in the face of all that medicine has recently effected, and can now accomplish, there comes a moment in every man's ailment when those of us who deal with his material side must confess our work is done, and that that higher power which each and all of us recognize in our spiritual selves must prevail if what we call the material is to survive and flourish. How this agent is to work, we know not; we simply affirm that, the case being in the hands of God, the source of all life, if that particular life is to be held, it must be through means beyond those He has so far permitted us to know and apply.

Pray understand that in making this affirmation, I do so with the distinct understanding that the best medical—using it in the sense material—aid has been brought to bear, so that no suspicion of ignorance or inadequacy of any sort can be alleged against the medical methods used. The best, then, that material man can do having been done and failed, that higher power must act if survival and efficient life is to remain.

The history of medicine shows that man's conceptions of the limits separating the two influences, the spiritual and the material, which govern his ailments have shifted their position, the material having gained ground, so that now medicine faces and overcomes conditions which formerly were abandoned as beyond it. The improvements in the handling of epidemic and contagious diseases fully exemplifying my assertion, render needless any citation of the advances in surgery, for instance, with which you are equally familiar. Having thus made such steady inroads upon the domain of what was supposed to constitute the field amenable to spiritual action alone, we are disposed to look with scant patience upon the claims of the latter as a working medical factor, especially as we have abundant proof of the failure of spiritual force to effect relief where the material meets with hourly success.

Spiritual action or force as expressed by mere mind concentration upon disease directly may, in time to come, cure it, but we believe the mastery which has been gained over disease has been gained, and will continue to be, by

mind acting through so-called material things furnished by nature, a belief which even the Christian Scientist accepts when we protect his child from diphtheria or his wife from puerperal fever.

The church, I apprehend, is not without blame for some of this impatience, seeing how strenuously, in early ages, it subordinated all things medical to its conception of the needs of the spiritual. However, I will not raise that issue, except so far as it touches the question before us. Admitting, however, that medicine, like all material agencies, has its limits, we come to the question before us: Does the spiritual, as manifested in "Christian Science," so-called, occupy a field not covered by medicine, or which cannot be better covered by it? You will observe that I am dealing with the question from the standpoint of material medicine, which is the same that you, and I, and every Christian Scientist occupy in living, moving, and conducting our daily affairs; we all act from it, no matter how unreal we may believe it, for we know that not to act from it would place us in positions of jeopardy from which, we likewise know, the spiritual would not deliver us, even though we believed that it could.

Immortal mind—God, Principle, Life, Truth, Love, Soul, Spirit, Mind. Such is the definition of the principle, or agent, which Christian Science professes to offer as a cure-all. According to it, Mind is "all in all," the only reality being the "Divine mind." It admits, however (page 3, *Science and Health*), that this assertion is not seen to be supported by sensible evidence until its principle is demonstrated by healing the sick, and thus proved absolute and "Divine." The field of medicine is, therefore, chosen for the initial demonstration of a force which can be indefinitely extended. If you have followed me, you realize that there is nothing new in this claim, so far as medicine is concerned. It is simply the reaffirmation of the predominance of the spiritual over material methods. It does not content itself with the claim to take up and bring to a sound conclusion, from the human point of view, problems which medicine abandons as beyond it, but invades the entire territory with a view to setting it aside as a whole. I say that, if Christian Science can do this, it can do anything. Those of us who love our kind, heartily wish it were true, and physicians, of all others, would hail it as the answer to the mighty problems which oppress us.

When a new idea or discovery is presented to any of us, the plan adopted to test the value thereof is more or less searching, in proportion to its importance, but the principle is the same for all, viz., a test by experts whose knowledge, honesty, breadth of comprehension, and ability are established. Medicine, ever seeking to push further and further its dominion over disease and death, has constantly before it new remedies—large sums in energy, education, intellect, and money are being expended the world over in this direction, and every measure of relief or cure is promptly heralded

and tested by eager experts. It is true that certain claims are viewed with less favor than others, because of their origin, and to this class Christian Science belongs. But, in spite of even this drawback, sooner or later all are taken up and tested; and so it has been with Christian Science.

The first step was to place it. Was it something new, or merely a reaffirmation of the spiritual as a therapeutic agent? We found it to be the latter. Looking further, it was easy to isolate and place it as a variety of that form of "spiritism" known to us as psycho or mind therapeutics—a something related to, and a part of, hypnotism—familiar to us through the writings and work of Liébault, Richet, Charcot, Heidenhain, Bernheim, and many since, and long recognized as the source of the power of the medicine-man, the dervish, and the fakir.

The work done throughout the world through mental suggestion and hypnotism is identical with that performed by Christian Science. The fact that the Christian Scientist strenuously denies this, only proves that he prefers his own designation to that which the best human material thought finds belongs to it; for if the conditions wrought out by the two processes are placed side by side, the ordinary every-day human mind finds them identical. Take, for example, that bible of the Scientist, *Science and Health*, separate yourself from disturbing surroundings, open its pages with a mind even somewhat prejudiced, set yourself seriously to the task of comprehending its various iterations and reiterations, its statements backward, its statements forward, its statements sidewise, and every other wise of its initial proposition throughout its 569 pages, and I know there are many of you who, long before you had fathomed its depths, would find yourselves in a state of mental vacuity fit for the action of "suggestion." Medicine has always recognized that the mental state of a patient influenced the course of his disease; that optimism aided him more than pessimism, and that, while it would not overcome organic changes, it would lighten his sufferings and add to his ability to curtail the crippling influence of disease. But the rôle which optimism must play in any given case was to be determined by the inherent forces possessed by the patient, those with which his optimism could be backed up in the contest waging; and so, to-day, a man paralyzed from a blood clot on his brain is encouraged to be up and about so soon as he has recovered from the initial shock of the injury to his brain; and another, with certain forms of heart disease, is put to exercising, so as to strengthen what heart he has. But, with each, some limit is set, to be determined by a careful estimate of the structural strength involved, which estimate, in turn, is based upon the investigation of a qualified expert in such matters. Such people, aided by a cheerful, hopeful mental state, live longer, and certainly are more efficient, more acceptable to their surroundings, than those in whom no such

frame of mind is invoked. Push mental or spiritual therapeutics further, push it to the point of commanding those people to get up, walk, run, do anything which a state of mental exaltation may suggest, and you soon find that the line of safety has been passed. Consciously or unconsciously, all practitioners of medicine employ mental suggestion, more or less, in the treatment of disease, and it is now not only acknowledged to be a resource, but the laws which govern its employment are being sought after with a view to placing it upon the same plane as other accredited remedial agents; but we must know its dangers as well as its blessings before we can give it unqualified endorsement. This is our duty and our rule in all allied questions. For the present, the best working formula in our possession is one to the effect that, in consequence of gradations, it can be used in a major and in a minor form. The former is that condition in which the suggestion is conveyed to the patient, previously put into a quiescent state, resembling unconsciousness, though he is really conscious so far as mental suggestion from the operator is concerned. The latter condition is merely a state either of mental negation, neutrality, or acquiescence on the part of the patient, such as some of us might reach in the reading of *Science and Health*, which fits him for "suggestion-treatment." The former is that to which the term hypnotic state is usually applied by the public at large, but in reality both of these conditions are to be included by the term, the difference being one merely of degree. I shall not detain you by any such speculations as are involved in a discussion of the kind of mental forces brought into play in these phenomena—whether there are such mental entities as a subjective and an objective mind, and if there are, whether all that has been built upon such a theory has any bearing upon our question—for we cannot afford to cloud the issue by departing from the safe ground of actual knowledge. I shall, therefore, proceed at once to tell you what we know this force in medicine can, and cannot, do. Every one is more or less amenable to it, and when in a state of such mental instability as accompanies disease or lowered vitality in all of us, we can be influenced to a greater or less degree—the personal equation, however, facing us here, as in all our dealings with our kind. But, quoting Lloyd Tuckey (who is undoubtedly one of the best exponents of the subject of psychotherapeutics), I think we may say that, the more a man's actions are the result of impulse rather than of reason, the more susceptible he is to external influences, and, therefore, to suggestion-treatment.

Turning next to the kind of diseases that can be favorably influenced by it, we find them comprised almost entirely in what we designate as functional disorders, mainly such as have become chronic, and especially such as we group under the term neuroses, such, for instance, as functional paralysis, St. Vitus's dance, asthma, palpitation, nervous headache, spinal irrita-

tion, neurasthenia, and many forms of dyspepsia, etc. (Tuckey, *Psychotherapeutics*, p. 63). That borderland of insanity occupied by dipsomania, the opium habit, and the excessive use of tobacco and other narcotics, offers an extensive field which should not be overlooked; and in organic diseases, especially such as are chronic, and in which pain is a potent factor, it has been used with benefit. Every practitioner is familiar with cases in which, through natural hyperæsthesia, the disabling effects of certain chronic ailments are far in excess of what the actual lesion warrants. The cross, the disgruntled, those lacking self-discipline, afford a fruitful field, exemplifying admirably the influence of mind in pandering to disorders. Here, mind, or, as the Christian Scientist puts it, "diseased mind," is having too full play, and here suggestion can be practised with benefit. Lloyd Tuckey, Bernheim, and others give ample illustrations.

I think I have said enough to show that in Christian Science we have no new or untried force in medicine. For forty years it has been before us, and the slowness of its progress with us is due to the fact that, entrusted by you, as we are, with all that you hold best and dearest on earth, we cannot consent to see a force, common as it clearly is to all sorts and conditions of men, the bad as well as the good, let loose until its dangers, as well as its blessings, are more clearly defined, recognized, and, if necessary, legislated upon. That there are dangers, the distinguished gentleman, Mr. Purrington, will clearly show, and you, as a leading body in this, our country, should hold up our hands, until such time as we can say of this, as of all other forces that we freely endorse, "Come and take of it, for we know its limitations." But, if you prefer to do otherwise, you need not expect to escape responsibility for the wickedness and dishonesty which now exploit it under the name of Christian Science.

7 EAST THIRTY-SIXTH STREET.

Correspondence.

LETTER FROM TORONTO.

Canadians and the Imperial Medical Services.—McGill University.—The Canadian Branch of the Victorian Order of Nurses.—The Proposed Dominion Medical Council.—Public Health Matters in the Province of Quebec.—The Ontario Bill for the Treatment of Inebriates.—Proposed Vaccination Legislation in Ontario.—Small-pox.—Medical Societies in Toronto.

TORONTO, April 1, 1901.

THE Militia Department at Ottawa has received information that a bill is at the present time before the Imperial House of Commons which proposes to admit medical men of the British colonies to the Imperial naval, military, and civil services. Where the examina-

tions and course of study at the principal colonial schools of medicine are in all respects the same as those practised in the United Kingdom, and subject to the supervision of the General Medical Council, medical men from Greater Britain shall be admitted to these services. This is the direct outcome of the war in South Africa. Several prominent Canadian surgeons offered their services for the war, and a complete field hospital was offered from Canada, but the Imperial government could not accept, owing to the medical law of England. It may be presumed that after the enactment of this legislation the medical institutions of the colonies will require to have Imperial approval of their examinations and course of studies, provided they desire their students to avail themselves of these opportunities.

McGill University, Montreal, never seems to lack for friends, for they are continually tumbling over one another in their eagerness to render financial assistance to this great institution. Recently it was announced at a meeting of the board of governors that Sir William Macdonald had signified his desire to contribute to the funds of the university \$150,000 more, he having already given something like \$2,500,000 to the university. Of this magnificent sum, \$75,000 will be taken to endow the chair of chemistry, and \$62,500 for the chair of botany, and \$12,500 will be added to the fund for the chair of physics. The medical departments are to be greatly improved during the coming summer. A large four-story wing will be added to the medical building, which will contain large lecture theatres, museums, and chemical laboratories. This is said to be part of a general scheme which, when completed, will alter the general appearance of the medical building. The total cost of the proposed addition will be borne by Lady Strathcona and the Hon. Mrs. Howard.

The local branch of the Victorian Order of Nurses held its annual meeting in Montreal within the last fortnight, and was presided over by the Hon. Senator Drummond. The report of the house committee states that the year just closed may be regarded as one of progress. The number of individual patients cared for during the year amounted to 529, and the number of visits paid was 6,751, in addition to 150 night calls. The fees derived from patients amounted to \$782.50. The report of the treasurer showed that, including a balance of \$7,821.51, the receipts had amounted to \$10,463.58, and the expenditures to \$5,126.24, leaving a favorable balance of \$5,337.34. The nursing staff at present in Montreal consists of six nurses. The order proposes to erect hospitals throughout the northwest as memorials to the queen, and toward this end the Dominion government has contributed \$6,000, and a gentleman of Montreal \$2,000. This money will be used for the purpose of establishing two hospitals of this class in that district. Senator Drummond was reelected president, and Dr. J. George Adami secretary.

The bill for a Dominion Medical Council which has just been introduced into the Dominion Parliament by Dr. T. G. Reddick, M. P., will, it is fully expected by the profession throughout Canada, soon be enacted. The bill provides for three representatives on the council from each of the Provinces of the Dominion, including the Northwest Territories. This will make a body of twenty-four, which, with three representatives from the homœopathic body, will bring the council up to twenty-seven. These representatives are to be appointed as follows: The president of the medical council of each province, *ex officio*; one from each provincial medical council, to be elected by that council; one to be appointed by the Governor-general in council from each province, who, with the three from the homœopathic body, will make up the total membership of the Dominion Medical Council. This medical council would act as an advisory committee to the Dominion government. They would also prescribe an examination for all students who desired to practise throughout the Dominion, each student to spend five years in the study of medicine, as at present in Ontario, the last year to be spent in the study of practical medicine. The bill has received its first reading.

The Quebec Provincial Board of Health has just published its annual report. From this it may be gathered that, however far Quebec may be behind in some things, she leads the Provinces of the Dominion in respect to birth rate and progressive legislation in regard to tuberculosis. According to the law passed on the 7th of June, 1900, every householder in that Province in whose household a death occurs from consumption must notify the local board of health within forty-eight hours from the occurrence of such death. Then it is imperative upon the municipality to order and cause to be made a disinfection of the premises and apartments which may have become contaminated through the patient. In this way does Quebec hope to check the ravages of consumption. The city of Quebec has the smallest death rate from tuberculosis of any of the Canadian cities, and Ottawa has the largest. Quebec's rate is 1.99 to each 1,000 of the population; Ottawa's is 3.12, Montreal's 2.87, Toronto's 2.41, Kingston's 2.17, and London's 2.67. Paris is said to have a death rate from this cause of 4.90, and New York one of 3.60. The recorder of statistics can take a justifiable pride in the birth rate of the Province. In 1898 it was 35.70, as against that of Ontario, 20.4. In 1899 it was 33.46, a decrease of 3,585. Even with this decrease, Quebec's birth rate is larger than that of any country in the world, except Germany's, which was 36.2 in 1898.

The Ontario bill for the treatment of inebriates seems about to be given the "go-by" by the government. The session is nearing its end, yet this important item of legislation has not been introduced. Its friends are beginning to despair of any action on the part of the present government. The bill was drafted over a year

ago, at the beginning of that session of Parliament. It has been approved of by the Premier and many of the members of the government, by the inspectors of prisons, and by the warden of the Central Prison, who is a medical man, but, with all this, the government persists in withholding the measure. A Provincial election is not far off, and the government may have cause in the future to wish they had acted differently in this and other educational matters.

A bill concerning revaccination is now before the Ontario legislature. It provides that persons having religious scruples with regard to vaccination shall not be required to have their children vaccinated before they can attend the public schools. The bill will be fought by the civic committee, and there is very little likelihood of its becoming law.

Small-pox exists in Ontario to the extent of 156 cases, and there are twenty-two different centres for infection. There has been a good bit of talk on the part of the antivaccinationists as to whether the outbreak is the genuine article or not, but the Provincial Board of Health is ever on the alert to prevent the possibility of the spread of the disease.

Toronto is again talking of an Academy of Medicine. There are three medical societies in the city, and, with a medical population of something like five hundred, no one of them can muster more than a score at a meeting. Amalgamation is deemed advisable.

Therapeutical Notes.

Antisepsis of the Nasopharynx.—*Presse médicale* for February 16th attributes the following prescriptions to M. Malherbe. They are to be used as anterior douches or by atomization.

Resolvent and antiseptic:

℞ Sodium salicylate. 22½ grains;
Distilled water. 4,500 minims.

M.

Resolvent, antiseptic, and astringent:

℞ Zinc sulphate. 4½ grains;
Distilled water. 4,500 minims.

M.

When there is much pain:

℞ Morphine hydrochloride. ¾ of a grain;
Distilled water. 1,250 minims.

M.

At the same time inhalations are prescribed:

℞ Compound tincture of benzoin. 1,350 grains;
Chloroform. 25 drops.

M.

A coffeespoonful in a pint of boiling water.

Or, when the inflammation has diminished, the following formula is recommended:

℞ Oil of eucalyptus. 6 parts;
Magnesium carbonate. 4 "
Distilled water. 90 "

M.

A coffeespoonful in a pint of boiling water.

RESPONSIBILITY FOR MEDICAL ATTENDANCE IN A
DIVIDED FAMILY.

ACCORDING to a recent newspaper report, a physician was called about a year ago by a lady to attend her infant daughter in Brooklyn, and, not receiving payment, brought suit recently against her husband. It appeared on the trial that the husband and wife did not live together, but there was no evidence to show that the physician knew of this fact until after most of the services had been rendered. A judgment given in favor of the plaintiff has been affirmed by the Appellate Division in Brooklyn, which held that the physician called by the mother was not chargeable with constructive notice that the father and mother did not live together, and that the father was responsible to the physician for the value of the services thus rendered.

The principle governing the liability of the husband and father for medical services rendered under such circumstances seems to be well settled. The rule is laid down in *The Law in its Relations to Physicians*, by Arthur N. Taylor, LL. B., as follows: "If the husband and wife are living apart by mutual consent, and the husband has entered into a contract with the wife to furnish her with a certain amount each month for her support and maintenance and all family expenses, and pays such amount, he will still be liable to a physician who renders services at her request, the physician not knowing that they are living apart, and that the husband makes her a fixed monthly payment in lieu of supporting her." (Page 86.)

As to the liability of the father for attendance upon children, the same work lays down the rule that "in case of voluntary separation of the parents, the father is *prima facie* liable for the support of the children, though they may be in the custody of the mother."

(Page 83.) It seems, however, that, if the wife abandons the husband without just cause, and takes the children with her, there is no implied authority in her to bind the father for medical attendance upon the children, her possession of them being unlawful.

At the same time, it is hard to see how the physician can be expected to divine that the obvious possession of the children by the mother is in contravention of legal right, and the judgment before referred to would seem to form a valid argument in this case also. The physician's claim stands on an altogether different basis from a trade claim. Many instances in which the physician is summoned are such as involve matters of life and death, and common humanity in such cases demands that the physician should not lose time before rendering his services in taking steps to protect himself, as the tradesman would and should do, before allowing indebtedness to be incurred.

THE SIGN OF THE ORBICULARIS PALPEBRARUM.

RARELY indeed does a sign or symptom of disease turn out to be of greater value than the original observer of it maintained. Such, however, according to L. Bard (*Lyon médical*, February 10th), seems to be the case with the sign of the orbicularis in the diagnosis of facial paralysis, which was described by Revilliod in the *Revue médicale de la Suisse romande* for October, 1889. M. Bard remarks that in cases of hemiplegia the paralysis of the temporofacial branch of the facial nerve is always much less marked than that of the cervicofacial, and that Revilliod's sign of the orbicularis is the most trustworthy means of demonstrating its existence. The sign is thus elicited: If a person with hemiplegia is asked to close both eyes at once, he closes them; he can with equal facility close the eye of the sound side while keeping that of the paralyzed side open, but he cannot close the eye of the paralyzed side alone while keeping that of the sound side open. This sign is said to be well-nigh constant in ordinary hemiplegia, provided the patient has preserved or regained sufficient consciousness. It is a necessary condition, however, that the patient should have been able to close either eye separately before the paralytic attack came on, and in regard to this we must depend upon the person's statement. Almost everybody has this power, but it seems that Boïadjew, a pupil of Revilliod's (*Thèse de Genève*, 1892), found that, out of 750 healthy persons, ten per cent. were incapable of closing one eye only, and twenty-five per cent. could close only one eye

alone (the left eye in seventeen per cent. and the right in eight per cent.). Inasmuch as these observations of Boïadjew's were made in Geneva, M. Bard suggests that they may have set the capability of closing only one eye higher than would be found to be the case in the world at large, from the facts that so many of the people of Geneva are watchmakers and that they are so generally practised in shooting.

M. Bard, as has already been hinted, rates Revilliod's sign higher than it was rated by Revilliod himself. It is as a distinguishing mark between facial paralysis of central and that of peripheral origin that Bard values the sign, for it is invariably lacking in the latter form. He admits, however, that Revilliod was inclined to think that the sign would prove to be constant in hemiplegia due to a central lesion, while it might be absent in certain cases of cortical hemiplegia due to a very limited lesion not involving the origin of the temporofacial branch.

THE THERAPEUTIC USES OF YEAST.

THE therapeutic possibilities of yeast grow apace. We have, from time to time, in our therapeutical notes and elsewhere, recorded the various uses to which yeast has been put in medicine. It is some considerable time since M. Thiercelin and M. Chevrey began their investigations into the use of brewers' yeast in the gastro-enteritis of children. They used, first of all, about a dessertspoonful of fresh yeast dissolved in from fifty to sixty grammes (approximately two ounces) of boiled water. After the administration of a purgative, this was introduced, at a temperature of 98° F., through a rectal tube, into the bowel, and caused to be retained as long as possible. The yeast was introduced three times daily. Subsequently, for convenience's sake, a small teaspoonful of dried yeast was used in place of the fresh. As a result of experiments on the subject, M. Nobécourt communicated to the Paris Society of Biology the conclusion that, while the vital processes of the *Torula cerevisiæ* were the principal causative factor in its action, there existed also simultaneously a chemical action. In 1900 Dr. Blancher (*Gazette hebdomadaire de médecine et de chirurgie*, February 10th), in a Paris thesis, showed that from one to two small teaspoonfuls of yeast in boiled water, administered *per os*, was even more efficacious than rectal lavements. He further showed that yeast was equally efficacious in the acute and chronic forms of gastro-enteritis of adults, in dysenteriform enteritis, in chronic mucocombranous enteritis, and also

in the gastro-intestinal troubles accompanying typhoid fever.

M. Combemale reported to the *Société centrale de médecine du nord*, in April, 1898, a marvellous reduction of sugar to between one fourth and one third of the previous daily excretion in a case of glycosuria, with other attendant symptoms of amelioration.

Landau, in 1899, had reported good results from the injection of from ten to twenty cubic centimetres into the fundus of the vagina in forty cases of leucorrhœa.

Again, as we noted in a minor editorial in our issue for June 23d, 1900, M. Marie reported eight cases of pneumonia in which excellent results were attributed to the use of yeast, administered in the first of them in consequence of numerous painful boils.

Finally, we note that Dr. E. Roos, *Privat Docent* of internal medicine at Freiburg (*Semaine médicale*, 1900, No. 45; *Nord médical*, February 15, 1901), finds yeast to exercise a favorable influence over habitual constipation. Either fresh yeast, simply dried at a temperature of 86° F., or yeast the vitality of which has been destroyed by an hour's subjection in an oven to a temperature of 298° F., may be used. The dose of the former is seven grains and a half, to be taken *per os* twice or thrice daily; of the latter, the dose is one half less.

The chemical theory of the action of yeast gains color from the fact of the devitalized yeast being equally efficacious with the simply desiccated yeast. The favorable action is said to manifest itself from the second day, and to continue for some time after the cessation of the treatment. Some flatulent distention, and occasionally slight colic, may occur, but these are said to be avoided, or at least diminished, by the use of the sterilized yeast.

This seems to be a very simple mode of treatment, easy of application and inexpensive, and the remedy, in the form of compressed yeast, is obtainable in most places, while the complaints in which it is said to be of value are such as fall within the province of the general practitioner. There should not, therefore, be much difficulty in obtaining ample confirmation of the virtues attributed to it or proof of their non-existence.

THE PUBLIC SPITTING NUISANCE.

IT is satisfactory to find that, at last, some steps are being taken to make the public understand that the board of health's ordinance forbidding expectoration in public vehicles, etc., will be enforced. Operations were begun on April 3d by the arrest of about a score of per-

sons for violating the ordinance, and fines ranging from \$3 to \$5 were imposed. Large fines will not be needed if a proper method is employed. It is not so much the severity of punishment as its inflexible and persistent infliction that tells. Many err in the training of children by letting offenses pass lightly at one time, and visiting them with condign punishment at another. The thing wherewith to impress the child's mind is, not the infliction by an irate guardian of vengeance for an offense committed, but the inevitableness of unpleasant consequences, as inflexible in their occurrence as is any operation of nature, *e. g.*, that if the child touches the fire it will burn itself. The child soon learns that the fire is not angry with it, neither does it exercise vengeance when it burns. The result is simply a matter of course. And so it should be, also, with adult offenders. It is the constant dripping of water that wears away the stone. It must not be forgotten, in dealing with the spitting nuisance, that long-established habit is hard to eradicate, and it may be that for some time many well-meaning persons will thoughtlessly offend. For this reason it would be well that for the first two or three offenses, unless accompanied by evident contumacy, the offender should be dealt with by reprimand only. But it is also essential that even the thoughtless offender should suffer the inconvenience of an appearance in court, that the less well-intending may not obtain undeserved clemency.

THE PHYSICIAN'S RESPONSIBILITY IN CASES OF X-RAY BURNS.

THE *Lancet* for March 23d, in a letter from its Paris correspondent, mentions a suit for damages brought by a lady against a physician before the Civil Tribunal of Paris. The lady had sciatica, and three times the physician subjected her thigh to the action of the Röntgen rays. The first sitting lasted forty minutes, and the second forty-five minutes. After the second sitting the thigh was red and inflamed, but the doctor made light of this fact and gave her a third sitting lasting an hour and a quarter. This was followed by a burn which confined the patient to bed for four months. Thereupon she sued to recover damages in the sum of 5,000 francs. The tribunal nominated Dr. Brouardel and M. Ogier as expert witnesses, and they submitted a report which the correspondent calls very remarkable. They took the ground that the doctor was not responsible, inasmuch as Röntgen-ray applications were not yet sufficiently understood in detail to enable anybody to say who would be injured by them and who would not, just as it was impossible to foresee which individuals of a body of men marching in the sun would be affected with sunstroke. At the same time, they said, it was to be regretted that the doctor had ignored the inflammation consequent on the second sitting. The court awarded the full amount of damages asked for, declaring that the doctor had acted imprudently, "more like a workman than a medical

man," and that his apparatus was defective. This judgment, it is added, is subject to appeal. There can be little doubt, we think, that the doctor was "imprudent."

THE ADMINISTRATION OF THE CITY HOSPITALS OF NEW YORK.

IN last week's News Items we published a statement, one that seemed to be final, to the effect that the Senate committee on cities of the legislature of the State of New York had struck out from the charter amendments those which provided that Bellevue Hospital and the allied hospitals should be given into the charge of a board of trustees. After we had gone to press, however, there came news apparently indicating a change of mind on the part of the committee, or else an error in the statement which had been given to the press. According to the later dispatches, the committee has decided to retain the charter revision commission's recommendations, and we now learn that the trustee plan for the administration of the hospitals in question has every prospect of receiving the sanction of the legislature. We discussed it at some length in our issue for March 2d, giving it our full approval. We are gratified, therefore, to learn of this final action on the part of the committee, and so, we do not doubt, will everybody be who is well informed as to the affairs of those hospitals and who has at heart the improvement of their administration.

THE BELL BILL.

THE Bell bill is dead. The extraordinary "compromise," which it was supposed by its promoter would meet all difficulties, *viz.*, the licensing of Christian Scientists to practise, only excluding them from treating surgical cases and cases of infectious disease, was foredoomed to failure. It is scarcely likely that people who deny the existence of disease at all can be trusted to be scrupulously exact in diagnosing infectious from other disease, even assuming that ignorance was presumptive evidence of capacity to do so. On the whole, the proposition reminds us forcibly of the newly married wife's suggestion for the proper settlement of all domestic questions. "Now, darling," she is reported to have said, "in order that we may always pull well in harness together, let us agree that you shall decide all the big questions that are ever at issue between us, and I will settle all the little ones—and," she added, thoughtfully, "I will decide which are big ones and which are little ones."

THE PLAGUE IN CALIFORNIA.

THE commission of experts appointed by the Secretary of the Treasury to investigate the condition in San Francisco as regards the existence of plague, has reported that there have been ten cases of plague in that

city since the beginning of the year, all of which have proved fatal. The disease has been confined to Chinatown, and has been only of the bubonic, or more mildly infectious, type; but proper precautions have been taken to prevent any grave developments, and the condition has never been such as to justify grave alarm. A committee of business men has consulted with the commission at Washington, and vigorous action has been adopted. All this is as it should be, and if this course had been adopted from the first, it is probable that, instead of inflicting injury on this important city, it would rather have prevented much detriment that has doubtless ensued upon the alarm created by the publicity given to ill-advised controversies.

THE RESPONSIBILITY OF THE WRITER OF FICTION.

A STATEMENT cited by the *Evening Post* for March 28th, if correct, points a very serious moral. It is there said that Dr. Wyllie, professor of medicine at the University of Edinburgh, summoned to visit a patient in a very low state, on inquiry, elicited the fact that the patient's favorite reading was *Sherlock Holmes*. The young man was in a very low state, and his tell-tale arm was dotted with hypodermic punctures. His admiration for the most popular of paper detectives had betrayed him into the cocaine habit. Dr. Wyllie uttered a severe stricture on Dr. Conan Doyle's knowledge of the action of drugs: "If such a man as Sherlock Holmes had existed, dosing himself as depicted by his creator, in a few weeks his opinion on anything would not have been worth having. Cocaine," said Dr. Wyllie, "is even more disastrous than morphine. It renders its subject vainglorious and pleased with himself, but blunts the intellect and blasts the imagination."

But there is even a more serious impeachment than ignorance or misrepresentation of the effects of the drug; and that is, heedlessness of the imitative suggestion it conveys. We are all familiar with the pernicious effects of suggestion as exercised on youth by trashy dime novels; but, whatever excuse can be made for lay purveyors of such putrescent literature, one ought surely to expect a literary physician to avoid opening the floodgates of suggestion of this sort.

THE ISOLATION HOSPITAL OUTRAGE IN ORANGE.

WE are glad to learn from the *New York Times* that five of the persons concerned in the recent wrecking of an isolation hospital in Orange, New Jersey, have been indicted and are likely to have to answer for their part in the wanton destruction of the hospital. Two manifestations of rank savagery have to be repressed in this instance—the assumption that a pest-house endangers the community and the contempt for law and order evinced in the forcible destruction of the hospital under the influence of that assumption.

News Items.

Society Meetings for the Coming Week:

MONDAY, April 8th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Harlem Medical Association of the City of New York; Gynecological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, April 9th: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Societies of the Counties of Jefferson (quarterly), Oneida (annual—Utica), Ontario (quarterly), Rensselaer, and Tioga (quarterly), N. Y.; Newark (private) and Trenton, N. J., Medical Associations; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Bergen (annual—Hackensack) and Cumberland (annual), N. J., County Medical Societies; Fairfield, Connecticut, County Medical Association (annual); Northwestern Medical Society of Philadelphia; Practitioner's Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, April 10th: New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Medical Society of the County of Albany; Tri-States Medical Association (Port Jervis, N. Y.); Pittsfield, Massachusetts, Medical Association (private); Philadelphia County Medical Society; Kansas City, Missouri, Ophthalmological and Otolological Society.

THURSDAY, April 11th: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; New York Laryngological Society (New York); Medical Society of the County of Cayuga, N. Y.; South Boston, Massachusetts, Medical Club (private); New London, Connecticut, County Medical Society (annual); Pathological Society of Philadelphia.

FRIDAY, April 12th: New York Academy of Medicine (Section in Neurology); Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, April 13th: Obstetrical Society of Boston (private).

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-commissioned Officers of the United States Marine-Hospital Service for the Fourteen Days ending March 28, 1901:

AUSTIN, H. W., Surgeon. Detailed as chairman of a board, to be convened from time to time as necessary, for the purpose of re-examining rejected immigrants.

CLARK, TALIAFERRO, Assistant Surgeon. Granted leave of absence for thirty days on account of sickness.

EAGER, J. M., Passed Assistant Surgeon. Upon expiration of leave of absence to proceed to Naples, Italy, for duty, relieving Assistant Surgeon V. G. HEISER.

GOODMAN, F. S., Hospital Steward. To report to the director of the Hygienic Laboratory, Washington, for duty.

HEISER, V. G., Assistant Surgeon. Upon being relieved from duty at Naples, Italy, to proceed to Washington and report in person for duty.

LAVINDER, C. H., Assistant Surgeon. Granted leave of absence for ten days from March 28th.

McMULLEN, JOHN, Assistant Surgeon. Upon being relieved from duty at Wilmington, N. C., to proceed to the Mullet Key Detention Camp, Florida, and assume command. To report at Washington *en route* to Mullet Key.

MATHEWSON, H. S., Assistant Surgeon. Granted leave of absence for three days from March 27th. To rejoin station at San Juan, Porto Rico.

MURRAY, R. D., Surgeon. Granted leave of absence for five days from April 9th.

RUSSELL, H. C., Assistant Surgeon. Granted leave of absence for eighteen days on account of sickness from February 21st.

Marine-Hospital Service Health Reports:

The following cases of small-pox, yellow fever, cholera and plague were reported to the surgeon-general during the week ending March 30, 1901:

Small-pox—United States and Insular.

Los Angeles, California.....	Mar. 19.....	15 cases.	
San Francisco, California.....	Mar. 2-9.....	8 cases.	
Washington, District of Co-			
lumbia.....	Mar. 18.....	16 cases.	
Jacksonville, Florida.....	Mar. 16-23.....	2 cases.	
Chicago, Illinois.....	Mar. 16-23.....	10 cases.

Small-pox.....	41	6	41	10
Tuberculosis.....	278	165	286	195

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from March 23 to March 30, 1901:

ALLEN, IRA A., Captain and Assistant Surgeon, is granted leave of absence for one month, to take effect on or about April 20, 1901.

BEASLEY, SHADWORTH O., Major and Surgeon, will report to the commanding general, Department of California, for transportation to Manila.

CROSBY, WILLIAM D., Major and Surgeon, will relieve HENRY S. KILBOURNE, Major and Surgeon, of his duties as medical superintendent of the army transport service, New York, and will proceed to the Presidio of San Francisco.

FOGG, JOHN S., Captain and Assistant Surgeon, will proceed to San Francisco for transportation to Manila.

GARLINGTON, JOSEPH C., Acting Assistant Surgeon, is relieved from duty at Fort Mott, N. J., upon the arrival of JOSIAH W. RICHARDS, Acting Assistant Surgeon, and will then proceed to Fort Terry, N. Y., to relieve JOHN J. GILHULEY, Acting Assistant Surgeon, who will then proceed to his home for annulment of contract.

HACK, CHARLES W., Captain and Assistant Surgeon, is assigned to duty with the first detachment of recruits to be sent from Columbus Barracks, Ohio, to San Francisco for transportation to Manila.

LONGINO, T. C., Captain and Assistant Surgeon, will proceed to San Antonio, Texas, to accompany troops to be sent from that department to San Francisco, where he will report for transportation to the Philippine Islands.

TANNER, WILLIAM T., Captain and Assistant Surgeon, United States Volunteers, is assigned to duty with the Third Battalion, Eleventh Infantry, and will proceed to Washington Barracks, to accompany that battalion to the Philippine Islands, where he will report to the commanding general, Division of the Philippines, for assignment to duty.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending March 30, 1901:

CRAWFORD, C. A., Assistant Surgeon. Detached from the *Dixie* and ordered to the *Constellation*.

DAVIS, E., Assistant Surgeon. Detached from the Naval Hospital, Mare Island, California, and ordered home, with permission to delay *en route*.

DECKER, C. J., Surgeon. Order detaching him from the *Monocacy* and ordering him to the *Oregon* is revoked, and he is ordered to the *Newark*.

EVANS, S. G., Passed Assistant Surgeon. Detached from the *Concord* and ordered to the *Monocacy*.

GROW, E. J., Assistant Surgeon. Detached from the *Glacier* and ordered to the *Isla de Luzon*.

HIBBETT, C. T., Surgeon. Detached from the *Newark* and ordered to the Naval Hospital, Cavite, Philippine Islands.

LEACH, P., Surgeon. Order detaching him from the *Oregon* and ordering him to the *Monocacy* is revoked.

LEDBETTER, R. E., Assistant Surgeon. Detached from the *Constellation* and ordered to the *Chicago*, via the *Dixie*, to relieve J. R. WHITING, Assistant Surgeon.

MCCLANAHAN, R. K., Assistant Surgeon. Ordered to the Asiatic Station, via the *Solace*.

PICKRELL, G., Surgeon. Detached from the Naval Hospital, Mare Island, California, and ordered home.

SPEAR, R., Passed Assistant Surgeon. Detached from the *Isla de Luzon* and ordered to the *Concord*.

WHITING, J. R., Assistant Surgeon. Detached from the *Chicago* and ordered to the *Dixie*.

"Pink Eye."—An epidemic of "pink eye" is said to have appeared in Philadelphia.

Lake Forest College and Ferry Hall Seminary, Illinois, have been closed in consequence of an epidemic of mumps. All the sufferers appear to be girls, not one of the young men having taken the complaint.

Unlicensed Practitioner Fined.—An unlicensed practitioner who was arrested in February at Stanley, Wis., for practising medicine without a license, has been fined fifty dollars. The fine has been withdrawn on his promise not to continue to practise.

The Cause of Cancer.—Professor Gaylord, of the University of Buffalo, claims to have discovered the cause of cancer. He was to lay his evidence before the faculty of the medical department of the University of Buffalo on the 4th inst.

A Medical Library for Milwaukee.—The Milwaukee Medical Society has appointed a committee to investigate and report upon a proposal which has been made for the establishment of a medical library in a new office building where quarters have been offered rent free.

A Bill to Abolish Coroners in New York City.—Assemblyman Henry, on April 3d, introduced at Albany a bill to abolish the borough coroners and coroners' physicians in New York city, and establish in lieu thereof a staff of medical examiners, thirteen in number, at an annual salary of \$5,000 each.

Vaccination Prosecutions in England.—The authorities of Leicester, the great anti-vaccination town of Great Britain, began the prosecution on April 3d of 60,000 defaulters under the vaccination acts. Six test cases had been started, but all had been withdrawn for various causes.

To Compel Hypnotists to Take Out Licenses.—The Senate committee on public health, at Albany, on April 3d, favorably reported Senator McCabe's bill compelling all persons professing to practise hypnotic treatment to take out a license. No license will be issued to hypnotists who have not put in four years of study and passed a successful examination.

The New Yale Medical School Building.—The contract for the new Yale Medical School building at New Haven has been given to the firm which has already put up about thirty buildings for Yale. The work will cost \$96,000. Recently the Yale corporation received a gift of \$100,000 from an anonymous donor for this new building.

Commencement Exercises.—The commencement exercises of the University Medical College of Kansas City, Mo., were held on March 26th. There were seventy graduates. After the exercises the Alumni Association gave its annual banquet in the Hotel Baltimore.—The University of Louisville, medical department, held its commencement exercises on March 28th at Macauley's Theatre, Louisville, Ky.

The Pennsylvania State Medical Council.—The State Medical Council met in the Internal Affairs Department at Harrisburg, Pa., on April 2d, and organized

by the election of Dr. Henry Beates, Jr., of Philadelphia, as president, and Dr. H. S. McConnell, of New Brighton, Beaver county, as secretary and treasurer, in place of Dr. Foster, of Pittsburgh, who was not reappointed.

Surgical Instruments are Taxed.—Judge Colt, in the United States circuit court at Boston, has dismissed the petition brought by the Massachusetts General Hospital for a review of the decision of the board of general appraisers, holding that a case of imported surgical instruments was not entitled to exemption from duty under paragraph 638 of the Dingley tariff act. The goods are dutiable at 60 per cent. under the act. The instruments were for use in the hospital.

A Plan for Nursing the Sick Poor of Cleveland, O.—The Graduate Nurses' Association of Cleveland (O.) is making an effort to provide adequate nursing for the sick poor of that city by the organization of a system of district nursing. The society is composed of women whose daily work carries them among the sick, and many of them among the poor. It is proposed to place the organization of the work in the hands of a board of directors composed of representative men and women of Cleveland.

The New York Medical Society for Clinical Research is the name of an association which has recently been organized with the following officers: President, Dr. Gutman; vice-president, Dr. Mandel; secretary, Dr. Lubman; and treasurer, Dr. Spivac. A library and laboratory have been established with a view to encouraging young physicians in original clinical research. Any licensed practitioner who is a graduate of a recognized medical college is eligible for membership.

A Letter Blamed for an Epidemic of Small-pox.—An epidemic of small-pox at Saginaw, Mich., seems to have been traced to a letter. The official in charge of the quarantine squad traced the fact that the first patient was a young lady who had recently had a letter from her lover, a soldier of the United States army in Alaska, in which he stated that he was just recovering from small-pox. The epidemic seemingly started by this letter is said to have had altogether thirty-four victims.

The Anti-spitting Crusade.—On April 1st the board of health of New York city sent out seventy policemen of the sanitary squad in citizens' clothes for the purpose of arresting all violators of the law regarding spitting on the floors of street and railroad cars and other public vehicles, ferryboats or public buildings. About twenty arrests were made in Manhattan and Brooklyn boroughs, the offenders being arraigned in the police courts. Some were held in \$500 bail for examination, some in \$50 bail, some were compelled to pay small fines, and others were discharged with a warning.

Dr. J. T. Burdick Assumes Charge of State Soldiers' Home Hospital.—Dr. James T. Burdick, of Brooklyn, on April 1st assumed charge of the hospital at the State Soldiers' Home, Bath, N. Y., as surgeon-in-chief. Dr. O. W. Smith, of Union Springs, who has held the place since September last, on retiring, entered a protest with the secretary of the board of trustees, alleging he had the right to withdraw his resignation before it had been acted upon by the board. Dr. Smith, about three months ago, resigned, and then sent a letter withdrawing the

resignation, but the board accepted it, and appointed Dr. Burdick.

Kansas College of Physicians and Surgeons.—The list of the graduating class at the seventh annual commencement of this college is as follows: C. D. Vermillion, D. A. Iliff, J. T. Peery, Dora E. Bowman, Henry Wilson Owen, J. Gertrude Ingraham, Arthur J. Lind, W. Hal McLeod, Andrew S. Pavlish, Leonard S. Wagar, William A. Swarts, Ralph L. Funk, William T. Todd, A. D. Updegraff, J. Candor McLaughlin, Joseph A. Beebe, J. Carroll Montgomery, J. H. Holliday, Fred H. Evans, M. A. Stockwell, J. Edward Attwood, E. C. Wickersham, G. M. Anderson, Oscar Francis Marcotte, T. Arthur Bayley, S. Carroll Whinery, J. S. Fulton, Earl Delaskia Tanquary, Mamie J. Tanquary, Bertha Eliza Wiggins, Anna M. Beveridge.

Death of the Christian Science Bill.—On April 3d, by a *viva voce* vote in the Assembly at Albany, it was decided to recommit the Bell measure, which has also become known as the anti-Christian Science bill, together with its various amendments, to the committee on public health. When Mr. Bell called up the bill he offered three amendments. The first of these permitted only licensed physicians to use or prescribe medicines or drugs; the second prohibited any but a licensed physician from treating contagious or infectious diseases, or performing operative surgery, and the third amendment recognized the practice of osteopathy under certain restrictions. When a vote was taken to recommit the bill it was carried by so large a majority that there was no call for a division. There is no prospect that the bill will be heard from again at this session.

Dr. Abraham Jacobi's Golden Anniversary.—Dr. Abraham Jacobi completed his fiftieth year as a physician on Thursday, April 4th. On April 4, 1851, he graduated from the medical department of the University of Bonn. His semi-centennial anniversary as a physician was observed on Friday, April 5th, at the Academy of Medicine, where he received and entertained his friends in the medical profession. An interesting feature of the reception was that it was given by Dr. Jacobi, and not by his friends. Dr. Jacobi entertained his friends by reading a paper on German Text-books Half a Century Ago; History and Reminiscences. On Saturday, May 5, 1900, the seventieth anniversary of the birth of Dr. Jacobi was celebrated at a dinner held at Delmonico's, which was attended by more than four hundred friends and professional associates.

A Court Held in a Hospital.—St. Catharine's Hospital, in Brooklyn, was temporarily turned into a police court on March 29th, when a man, forty-four years old, a patient, was examined on a charge of attempted suicide. Mr. Lemon, the magistrate of the Ewen Street Police Court, accompanied by his official stenographer, a clerk of the court, a police captain, two court officers, and the assistant district attorney, conducted the examination. They were joined by Dr. Daly, who took the party to the man's cot. Two nuns were at his bedside. He could scarcely speak, and when the complaint was read to him and he was asked if he had tried to end his life, he replied feebly that he was guilty, and muttered something about not knowing what he was doing at the time. When the magistrate dismissed the case, the action brought a faint "Thank you" from the patient, who had

shot himself a month ago because his physician told him he had consumption. The court proceedings were held in the hospital to relieve the police from keeping a patrolman stationed there.

The Special Lectures at the New York School of Clinical Medicine.—The first of the series of special lectures at the New York School of Clinical Medicine was held at the school, No. 328 West Forty-second Street, on Friday, April 5th, when a clinical lecture was delivered on the Examination of the Male Urethra by the General Practitioner, with clinical demonstrations, by Dr. Ferdinand C. Valentine. On Friday evening, April 12th, Dr. Thomas D. Crothers will lecture on Medical Questions of the Responsibility of Alcoholics, Opium and other Drug Takers. The rest of the series are as follows: April 19th, Complicated Fractures: Diagnosis and Modern Treatment, by Dr. Thomas H. Manley; April 26th, Diagnosis and Surgical Treatment of Prolapsed Kidney: With Clinical Demonstrations, by Dr. Augustin H. Goelet; May 3d, Treatment of Strangulated Hernia, by Dr. Carl E. Pfister; May 10th, Pelvic Trilogity in the Diagnosis of Diseases of Women, by Dr. A. Ernest Gallant; May 17th, The Technics of Major and Minor Amputations, by Dr. Robert H. Cowan; May 24th, Treatment of Obesity, by Dr. Heinrich Stern; May 31st, Diseases of the Stomach: Practical Examinations and Treatment, with Demonstrations on Patients, by Dr. Freeman F. Ward; June 7th, Psoriasis and Acne, Effective and Practical Methods of Treatment; Clinical Demonstrations, by Dr. W. R. Inge Dalton.

The Rocky Mountain Industrial Sanatorium and its Plans.—The avowed object of an organization of Denver (Col.) physicians in establishing and maintaining the Rocky Mountain Industrial Sanatorium, which has just been incorporated there, is to save the lives of tuberculosis sufferers. The organization aims to be national in its scope, and has the indorsement and support, it is asserted, of many of the foremost physicians of the United States. Its purpose is to aid those tuberculosis patients in poor or moderate circumstances who come to Colorado and other mountain States in the hope that the climate and altitude will aid in effecting a cure, and who, almost invariably, either from lack of means or proper direction, are immediately surrounded by conditions which preclude improvement or recovery. Their plan provides for the erection of a sanatorium about twenty miles from Denver, to be conducted as an industrial colony. A large amount of money will be required. This, it is expected, can be raised by the "cottage endowment plan." To secure these endowments by individuals, fraternities, clubs, societies, churches, college alumnæ, labor unions, etc., the Young Woman's Sanatorium Auxiliary has been organized. A branch of this auxiliary will be established in every city and town in the United States.

The Standardization of X-ray Methods.—S. H. Monell, M. D., chairman on the committee on standards of the Röntgen Society, in order to standardize the methods of x-ray work, has invited experts to send to him their suggestions on something over a score of points. Included among these are: Standard x-ray examination table, adjustable for all parts of the body; standard method of posturing each part of the body for a standard picture; standard means of fixing parts immovably during a standard exposure; standard complete definition of what a "standard exposure" should be (of medicolegal value); standard landmarks to be pictured in the negative as in-

herent proof that a standard exposure was made (a medicolegal necessity); standard technique for picturing correct relation of bones and joints; standard technique for picturing contrast for diagnosis of soft parts; standard technique for picturing the different calculi, vesical, renal, and gall-stones; standard technique for x-ray eye work; standard technique for x-ray heart and lung diagnosis; a standard leaflet of brief directions which the physician who does not do his own developing can send with his plates to any fair photographer as a ready guide to proper treatment of an x-ray negative to secure the picture; and, standard technique for therapeutic administration of x-rays with proper precautions.

The Bubonic Plague.—Foreign reports show that the plague is pretty well scattered over the world. There were fifteen new cases and nine deaths in January in Rio de Janeiro. Because of its appearance in Cardiff, Wales, the Canary Islands have proclaimed quarantine against vessels from Wales. Deaths from the plague are reported from Hongkong, while at Cape Town it has been spreading quite rapidly; in Mauritius there were sixteen new cases and fifteen deaths for the week ending February 1st. There were reports of the plague at three different places in Australia. It prevails in parts of Russia, and in the British East Indies, in Argentina, in the Straits Settlements, and has until recently been more or less prevalent in Japan and in Turkey. In the Patna district in India, 5,007 persons have died of the plague in three months, while there has been almost as large mortality in adjoining districts. In Bombay city 1,645 have died in that time, and 1,835 in Belgaum district.

Small-pox.—There seems to be little abatement of the disease in New York city, several new cases being reported almost daily. The health board's plan to have a new hospital on North Brother Island was defeated on April 2d by the Board of Aldermen.—Several new cases are reported at Newark, N. J., various points in Wisconsin, at Cleveland, O.; New Castle, Del.; in Webster county, West Va., where the circuit court at Addison adjourned because of the prevalence of the disease, and at Harrisburg, Pa., where a number of employees of a steel company quit work rather than submit to vaccination.—The Grand Jury of Orange, N. J., have brought in indictments against the five men believed to be implicated in the burning down of the pest-house on March 10th.—Pupils in the Philadelphia public schools must submit to compulsory vaccination. That is the opinion of the supreme court, which, on April 1st, dismissed the appeal of Charles T. Field from common pleas court decision refusing to order Martha L. Robinson, the principal of the Keystone Grammar School, to admit Mr. Field's daughter, who had not been vaccinated. Quoting from a previous decision, the court said: "School directors, in the exercise of a sound discretion, may exclude from the public schools pupils who have not been vaccinated." The school directors are the judges of the wisdom of the plan.—According to the monthly publication of the Marine-Hospital Service in the Treasury Department, small-pox still continues to be prevalent in many parts of the United States. Of the cases reported for the three months ending March 29th, there were 1,190 in Colorado, 2,251 in Kansas, 1,985 in Minnesota, 578 in Nebraska, 416 in New York State, 636 in Ohio, 690 in Oklahoma, 102 in Pennsylvania, 308 in Tennessee, 432 in Texas, 597 in Utah, 257 in Virginia, and a smaller number of cases in each of a number of other States.

The Baltimore County Medical Association.—The monthly meeting of the Baltimore County Medical Association was held on March 21st. Dr. H. Burton Stevenson presided. Interesting papers were read by Dr. R. Percy Smith, Dr. L. M. Allen, and Dr. J. W. Harrison.

The Associated Physicians of Long Island have accepted the invitation extended by Sag Harbor to hold their annual June session there, and a committee of citizens has been appointed to take the matter of entertainment in charge. About one hundred physicians are expected.

The Medical Association of the Greater City of New York.—At a stated meeting of this association to be held at the Academy of Medicine on April 8th, a paper will be read on Food as a Factor in the Causation of Disease, by Dr. Elmer Lee, to be discussed by Dr. R. E. Van Gieson, Dr. H. S. Stark, Dr. Edward Quintard, and Dr. C. N. B. Camac. Dr. Henry W. Borg will present a paper on Gliosarcoma of the Base of the Brain, Pressing upon and in Front of the Left Lobe of the Cerebellum, and Dr. Howard Lillenthal will make some remarks on the surgical aspects of the case.

The New York Academy of Medicine.—The section on surgery of the New York Academy of Medicine will meet on Monday evening, April 8th. The order of business will be: Presentation of patients: Case of cancer of the rectum, removed five years ago, with no recurrence, by Dr. J. F. Erdmann; a case of cancer of penis, with removal of glands by Lennander's method, by Dr. V. C. Pedersen; and a paper on Cancer of the Rectum, with Demonstration of New Methods of Examination, by Dr. J. P. Tuttle. The section on otology will meet on Wednesday, April 10th. The order of business is as follows: Exhibition of specimens and new instruments; presentation of specimen of tuberculosis of the ear, with history of a case, by Dr. H. L. Swain; Tinnitus Aurium; Some Remarks on its Causes and Treatment, by Dr. Thomas J. Harris; Tympanic Vertigo, Due to Obstruction in the Eustachian Tube, by Dr. William P. Brandegee.

Births, Marriages, and Deaths.

Married.

ELEY—FORREST.—In Crittenden, Virginia, on Thursday, March 28th, Dr. L. L. Eley and Miss Edith Forrest.

MURRAY—WOODS.—In Fair Oaks, Pennsylvania, on Monday, March 25th, Dr. Charles S. Murray and Miss Sarah Woods.

WISEMAN—STARCK.—In Hermann, Missouri, on Sunday, March 24th, Dr. F. W. Wiseman, of St. Louis, and Miss Ella Starck.

Died.

BALDWIN.—In Dover, N. J., on Monday, March 25th, Dr. Edwin C. Baldwin, formerly of Baltimore, in the eighty-seventh year of his age.

EVELYN.—In Cleveland, on Sunday, March 24th, Dr. Robert S. Evelyn.

LIGHTHILL.—In Newark, N. J., on Tuesday, March 26th, Dr. Edward B. Lighthill, in the seventieth year of his age.

LUCKETT.—In Washington, on Saturday, March 30th, Dr. William Fleet Lockett, in the sixty-third year of his age.

MAUGHS.—In St. Louis, on Saturday, March 23d, Dr. G. M. Maughs, in the eightieth year of his age.

NELAN.—In Pittsburgh, on Thursday, March 28th, Dr. James R. Nelan, in the fiftieth year of his age.

Pith of Current Literature.

Medical Record, March 30, 1901.

Some Fallacies of Therapeutics. By Dr. George L. Peabody.—The fallacy in the use of bitter substances as appetizers is one of the author's instances. Strychnine salts—if they have any effect in the way of sharpening the appetite after they reach the stomach—are efficacious only by virtue of a possible local irritant action. The author explains the action of these salts as being due to the sense of taste, or to the stimulation of the saliva, which, in turn, stimulates the secretion of the gastric juice, and this increased flow of gastric juice announces its readiness for work by calling for food to work upon. If this is the explanation, it discredits the use of similar agents in any other form than one which will stimulate the sense of taste, hence the uselessness of all methods of administering them in pills or capsules. The author refers to the popular ignorance of the fact that the phenomena of intoxication are in themselves incidents of little pathological moment; what the heart, arteries, and tissues generally object to is the damaging effect of the alcohol upon them, whether their owner gets drunk or not. In regard to tannic acid, the author demonstrates that there is no warrant for the belief that after its absorption it can produce styptic or hæmodynamic effects upon remote organs; we can no longer hope to check bleeding from kidneys or uterus by giving tannin *per os*. The futility of giving ergot to arrest pulmonary hæmorrhage is commented upon, and the therapeutic uselessness of lithium carbonate and acetate is pointed out. The author regrets the present-day fallacies relating to gaseous or aerial disinfection; and he asserts, as his concluding instance, that the inhalation of oxygen is often practised upon very absurd premises. The sphere of usefulness of oxygen inhalation under normal atmospheric pressure is very limited.

Ionization in its Physiological and Pathological Relations. By Martin H. Fischer.—The theory of ionization offers a new field for investigation in the realm of medicine. Its application to the problems of physics and chemistry has elucidated many obscure points, and, in the solution of the problems of medicine, the author believes, it will yield yet greater results. In this article the author adduces some of the evidence to show that in dealing with the action of dilute solutions of inorganic substances we are dealing with the action of their constituent ions. This fact, he says, is ever to be borne in mind when we consider physiological, pathological, and pharmacological problems involving the presence of inorganic substances.

Creosote in Pneumonia: A Résumé. By Dr. I. L. Van Zandt.—The author has given creosote in pneumonia—one drop every three hours—with very good results, and he is somewhat disappointed if his case is not ready for dismissal by the third or fourth day. In cases that persist longer, there is generally an amelioration of symptoms and the coming of an appetite. There is generally a gradual decline in the fever, with only slight moisture of the skin, a critical sweat being rare. Of sixteen patients treated, four were dismissed on the second, five on the third, one each on the fourth, fifth, sixth, seventh, and eighth, and two on the tenth days. Several other writers quoted give similarly encouraging reports.

Orchid Culture in its Relation to a New, Improved, and Completely Effective Method of Disinfection. By

Dr. J. M. W. Kitchen.—The author has found that, in the application of destructive vapors to disinfecting greenhouses, the greater the number of points of generation the greater the success, and he suggests that the same principle be applied to house disinfection, using several generators in a room, in corners, closets, and under beds.

Medical News, March 30, 1901.

Report of the Committee of the Medical Board of Bellevue Hospital, Appointed January 2, 1901, to Investigate and Report upon Questions Relating to the General Administration of the Hospital.—The inefficiency of the paid employees is pointed out as one of the things which is apt to render permanent improvement difficult. Complaint is made of the poor accommodations furnished to the staff, doctors and employees alike, and corrective changes are suggested. An increase in the *per capita* allowance is asked for. The illustrative statistics add special emphasis to the recommendations set forth.

Vaccination, Clinically Considered. By Dr. Frank S. Fielder.—In an extended article this subject is considered. The points particularly emphasized are: 1. Complete natural immunity to vaccination is practically unknown, and, in primary cases, delayed vesiculation, raspberry excrescence, and abortive course, mean poor virus. 2. Generalized vaccinia, aside from cases in which the eruption is spread by self-intoxication, is very rare. Cases of doubtful diagnosis may be tested by the inoculation of lymph from one of the vesicles into another subject. 3. Immunity is acquired about the time the areola is at its height—eight to ten days after vaccination. If small-pox appears at this time it will be mild. If the eruption appears before the disease has reached the areolar stage, the disease will not be much modified by the vaccination. 4. Vaccination of the pregnant woman does not protect her child. The fœtus may have small-pox *in utero*. A child born while the mother has small-pox is not protected, and will probably develop the disease before there is time to secure immunity by vaccination. 5. The duration of immunity to small-pox is probably five years, while the duration of immunity to revaccination is, according to the author, probably two years, or under. A person who is immune to small-pox can often be successfully revaccinated. Revaccination is as important as primary vaccination. 6. All vaccine virus should be subjected to rigid physiological tests before issuance, and should be retested monthly so long as it is on sale. 7. Vaccination should be performed under aseptic precautions, and the virus must be thoroughly rubbed, scratched, or pricked in. Vaccination shields do more harm than good. 8. Cases of infected vaccination should be cared for by the physician—not by the mother. 9. The destruction of the vesicle does not impair the protective power of vaccination, and if signs of mixed infection appear, the vesicle should be opened and the wound cleaned and treated upon general surgical principles.

The Method of Preparation of Vaccine Virus in the Vaccine Laboratory of the New York City Health Department. By Dr. J. H. Huddleston.—The calves are chosen for their health and the good quality of their skin. After vaccination they are killed, and if disease is found at autopsy, the virus obtained from them is rejected. The posterior abdomen and the inside of the thighs of female calves are the surfaces chosen for inoculation, and aseptic precautions are taken in an

operating room with modern equipments. On the sixth day after vaccination the virus is collected, weighed, and emulsified by passing it through a mill on which a mixture of sixty-six per cent. of glycerin and thirty-three per cent. of water flows. The proportion of virus to glycerin and water is usually one to three. Fresh virus always contains a large number of saphrophytes, but the majority die in a few weeks; those that remain are non-pathogenic. The virus is tested before its issuance on five unvaccinated children, and, after issue, retests are made at more or less regular intervals.

Boston Medical and Surgical Journal, March 28, 1901.

The Embryological Basis of Pathology. By Charles Sedgwick Minot, LL. D.—In his discussion of pathological differentiation, the author concludes that: (1) The process in its essential features is identical with the process of normal differentiation; (2) the character of a tumor depends primarily upon the layership of the cells producing it; (3) normal differentiation impedes and limits the formation of tumors, precisely as it does of further normal structures, so that tumors arise most readily from undifferentiated tissues and may then be heteroplastic; arise less readily from differentiated tissues and are then always homoplastic; and arise un-readily, or not at all, from the most highly specialized tissues. Substituting the term "differentiated tissue" for "tumor," each of these three conclusions might be advanced as a law of normal development. To the physician, physiological morphology promises to surpass greatly in practical importance even the bacteriology of our time, and the author believes that when we understand the physiological factors which bring about structure, we can acquire control over cellular differentiation, and shall ultimately be able to prevent some of the most formidable diseases over which now we have little control. The diseases more particularly referred to, the author designates as morphogenetic—due to errors of morphological differentiation.

A New Method of Treating Fractures. By Dr. Leonard F. Hatch.—The author's principle is to convert all compound fractures into simple ones. In the case of simple fractures he makes them compound and then makes them simple. He asserts that we should not be deterred from operating on fractures by fear of sepsis, and that it is unscientific to adopt a blind way when a better presents. Operative intervention would be warranted if it did nothing more than to relieve the pain and swelling, which it certainly does. It shortens the process of repair at least one week, and it reduces the chances of deformity and non-union to a minimum. Fifteen illustrative cases are appended. The results are encouraging and, in several cases of fractured patellæ, the advantages of the operative method are clearly demonstrated. The author also writes in favor of the ambulatory splint for fractures of the leg.

Mumps in Pneumonia; Boroglyceride. By Dr. Charles W. Dulles.

A Brief Summary of Nine Cases of Lobar Pneumonia Treated by Ice Pack. by Dr. George L. Collins.—In these cases contemporary signs of bronchitis were not considered to contraindicate the use of the ice pack. High temperature was the indication in each case. Lowered temperature was the indication for removal. The number of white corpuscles invariably began to fall with the temperature, but reached normal in no less than one week after the temperature was normal. The

ice pack had no apparent effect in either shortening or prolonging the duration of the physical signs.

Journal of the American Medical Association, March 30, 1901.

Recent Advances in Dermatology which are of Service to the General Practitioner. By Dr. L. Duncan Bulkley.—Referring to phototherapy and the x-rays, the author states that it is perhaps too soon to form a correct opinion of the real value of this method of treatment. He recalls the enthusiastic reports attending the earlier use of Koch's tuberculin in lupus, and he believes that there is reason to fear that the hopes held out by the Finsen phototherapy may also prove illusory.

Hyperacidity a Cause of Skin Diseases. By Dr. W. R. Inge Dalton.—The author is inclined to think that the bond which connects the diatheses of the dermatoses with gout, rheumatism, diabetes, arthritis, and asthma is generated by indiscretion of diet; that the chyme passing in a hyperacid condition from the stomach through the pylorus into the second stomach entails such increased labor upon the duodenum that its contents cannot be rendered sufficiently alkaline for physiologic metabolism. This acid dyscrasia he believes to be the *fons et origo* of the pathologic lesions, which lead certainly to nearly all diseases of the skin, save the contagious exanthemata.

Acute Suppurative Folliculitis of the Scalp. By Dr. William S. Gottheil.

Operations for Injuries to the Median and Ulnar Nerves. By Dr. R. Brindley Eads.—In these cases, provision of ample operating space is the first requisite to success. Suppuration may be prevented by cleanliness, hæmostasis, and avoidance of chemical irritants and drainage tubes. Chromicized catgut and fine silk furnish the best suture material. Tension may be overcome by position, and loss of substance by nerve stretching and bridging by the flat method. Immediate suture of clean nerve ends accurately approximated is conducive to early functional restoration. Relaxation by position, rest, and protection by suitable splints, are conducive to successful union. Asepsis in primary, and antiseptis and asepsis in secondary, nerve suture should be the practice of to-day.

Pathological Conditions Found in Meat Inspection. By D. E. Salmon, D. V. M.—A brief review of the meat inspection service illustrating the importance of having experienced and educated men on guard, to withdraw affected carcasses from the meat supply of the country.

The Treatment of Prolapse of the Rectum. By Dr. Joseph M. Mathews.—The author concludes that: (1) In all cases of prolapse of the rectum of the second or third degree, colopexia is to be preferred to all other procedures; (2) it is the least dangerous of any surgical procedure advised for prolapse; (3) the uninterrupted suture should be used in preference to the interrupted, especially in cases where the mass is large or the walls of the gut much thickened.

Sanitary Conditions of Peking. By Dr. John Inglis.—The conditions are those of unspeakable filth, and the author believes that one of the conditions that ought to be required of China before admitting her to the society of enlightened nations, is that she should make her capital less dangerous as a place of residence by ridding it of the unsanitary conditions that give rise to the enormous prevalence of those diseases that are

the product of filth. Sanitary science applied to Peking would make it as healthy a city as New York or Chicago.

Thyroid Tissue in the Larynx and Trachea. By Dr. Otto T. Freer.

Open Treatment of Suppuration of the Knee Joint. By Dr. W. J. Mayo.

Quantitative Tests for Proteolysis. By Dr. A. L. Benedict.

The Rage for Rapid Operating and the Importance of Saving Time in Surgical Operations. By Dr. John S. Miller.—The author points out that, in a complicated abdominal case, the anæsthesia and the exposure and manipulation of the peritoneal cavity for from half an hour to three hours, with a physically bankrupt patient, is a very important factor in the prognosis. Time, therefore, is as important an element to success as asepsis or correct methods in operating.

Venereal Disease as a Social Problem. By Dr. W. C. Gates.

Circumcision in Restricting the Spread of Syphilis. By Dr. Harold N. Moyer.

Report of the Special Committee of the Section of State Medicine of the American Medical Association, Appointed to Inquire Whether and When the Gonorrhœic may be Permitted to Marry, and Whether the Matter is a Proper One for Regulation by Statute.

Purulent Otitis—Its Treatment and Prevention by the Family Physician. By Dr. H. Gradle.

Primary Union in a Gunshot Wound. Report of a Case. By Dr. Albert Soiland.

Case of Typhoid in an Infant. By Dr. Minnie C. T. Love.

Philadelphia Medical Journal, March 30, 1901.

Atmocausis: Its Value in the Treatment of Severe and Uncontrollable Uterine Bleedings (Uterine Arteriosclerosis). By Dr. Samuel W. Bandler.—While the value of atmocausis in other conditions is still a question of personal experience, the author asserts that there is no doubt that uterine bleedings, especially the bleedings of the climacterium, and the uncontrollable hæmorrhages occurring at this period and in earlier years, are positive indications for its use, especially when curettage and other local methods are of no avail. As the author's experience and the investigations of others seem to demonstrate that the greater proportion of such cases is due to local degenerative changes, he concludes that atmocausis, if not a specific, is at least the best method of treatment for uterine arteriosclerosis.

The Coexistence of Carcinoma and Fibroma in the Corpus Uteri. By Dr. W. A. Newman Dorland.—This coexistence may manifest itself in one of three distinct ways, given in their order of frequency as follows: 1. Fibromyoma of the corpus uteri with carcinoma of the cervix. 2. Fibromyoma of the corpus uteri, with associated adenocarcinoma of the endometrium. 3. True cancerous degeneration of an adenomyoma, the malignant changes originating in glandular vestiges included in the uterine growth, or the carcinomatous disease invading the benign growth by extension from an endometrial adenocarcinoma through contiguity of tissue. The author's case belonged to the third class.

Shock in Abdominal Operations. By Dr. Fenton B. Turck.—The author emphasizes two things. One is the decreased resistance against infection when shock is present. The second is the increased resistance against in-

fection, produced by the internal application of heat while preventing shock, or reducing shock when present. Especially is this most marked when the heat is applied within the colon, stomach, or the abdominal cavity, the latter two locations being the most effectual.

A Practical Modification of the Phenylhydrazine Test for Glycosuria. By Dr. Robert N. Wilson.

How to Prevent Stammering. By Dr. G. Hudson Makuen.—Few, if any, children stammer from the outset. Though a tendency to stammer is inherited in many cases, in all cases stammering is an acquired defect, and a child stutters because he has not yet learned to combine the art of ideation with that of oral expression. As the trouble arises from faulty mental action, the first indication is to direct the mental process into normal channels. The author asserts that careful direction and management at the very inception of the trouble will almost surely prevent the formation of the habit.

Bell's Palsy Associated with Complete Anæsthesia in the Territory of the Fifth Nerve. By Dr. James Hendrie Lloyd.

Lancet, March 23, 1901.

Public Health and Housing: The Influence of the Dwelling upon Health in Relation to the Changing Style of Habitation. By Dr. J. F. J. Sykes.—The third of the Milroy lectures upon this subject. After discussing the influence upon the public health of the various domestic conveniences (water closets, sinks, etc.), of the usage and misuse of dwellings, and of pressure of population and overcrowding, the author briefly summarizes the question of the healthy housing of the people as follows: The relief of the pressure of population will ultimately be brought about by the improvement of the means of transport between the suburbs and urban centres; the building of additional houses in the suburbs; the attraction to the suburbs of the better classes and those able to live at a distance; and the slow but ultimate relief of the pressure in the middle zone by the movement and circulation of the population and the gradual vacating of houses occupied by single families and subletting in separate dwellings. The remedy for the dilapidation and deterioration of dwelling houses will be brought about by the reconstruction of the worst areas and houses into healthy flats; the adaptation of the best streets and houses of an unhealthy "floor" type to a modern "flat" form of construction to suit the altered mode of usage; and the supplementing of sanitary laws and bylaws with the dwelling as the basic unit.

Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. By Dr. J. M. Bruce.—The second of the Lettsoman lectures upon this subject. In this article the author describes the clinical characters and course of the affections of the heart and arteries in connection with various influences, such as tobacco, alcohol, gout, obesity and glycosuria, cardiac strain, syphilis, and nervous strain.

Blackwater Fever. By Dr. J. W. W. Stevens.—The author concludes that blackwater fever is essentially a malarial infection in which quinine is the most common immediate determining cause of intoxication. Bearing in mind that the absence of parasites does not necessarily exclude malaria, there is actual evidence of the existence of a malarial infection in blackwater fever, brought from the following five points of view: (1) existence of parasites during the attack; (2) pigment and uninuclear percentage increase; (3) parasites before the

attack; (4) parasites after the attack; and (5) post-mortem evidence.

Protection from malaria will ensure protection from blackwater fever. Complete protection from malaria may be attained without the taking of any quinine, by paying scrupulous attention to clothing and the use of the mosquito net. It is only exceptionally that the action of quinine can be excluded in cases of blackwater fever; in such cases it is suggested that isolation may be responsible for the attack. In all the author's cases quinine had been given, and the interval between its administration and the onset of hæmoglobinuria was very constant—*i. e.*, from four to ten hours.

Three Cases of Acute Diffuse Septic Peritonitis Resulting from Appendicitis; Operation; Recovery. By W. G. Richardson, M. B.—The three cases here reported are strikingly similar and are typical of the "fulminating" form of acute appendicular inflammation which is the most fatal of all varieties. In the initial stages they were not distinguishable from ordinary cases of appendicular inflammation in which recovery could take place either by resolution of the inflammatory process or by limitation of the disease to the formation of an abscess; yet in the more advanced stage, and without warning, the life of each patient was placed in immediate danger and death could only be averted by immediate operation, performed with the minimum amount of preparation that could be desired. In each of these cases there was a premonitory stage, lasting for a few hours, during which the patient felt unwell and uneasy in the abdomen. This was followed by the sudden development of acute symptoms, which subsided somewhat after several hours of severe pain. This lull was followed in about twenty-four hours from the initial acute attack by strikingly violent and sudden increase of all symptoms, and in seven or eight hours the abdomen was found to be full of pus. In each case the appendix was seen at the operation to be acutely inflamed, without any surrounding adhesions, and to have a gangrenous perforation through its walls. In all the three cases here reported the abdomen was simply mopped out with gauze, and gauze wrung out in normal saline solution was used as a drain, instead of a drainage tube. The gauze was easily and painlessly removed on the fifth day, and all the patients made good recoveries. The author makes it a rule to remove the appendix in all very acute cases of appendicular inflammation which at the end of twenty-four hours do not improve in *all* the symptoms. He believes that by so doing a large number of lives have been saved.

Resection of the Superior Cervical Ganglion of the Sympathetic for Glaucoma and its Results. By H. W. Dodd, F. R. C. S.—The author reports a case of glaucoma, occurring in a woman aged forty-four years, in which the removal of the superior cervical ganglion on each side was immediately followed by a marked reduction to normal of the tension of the eyeballs. The patient's eyeballs remained soft for about two months, when symptoms of glaucoma reappeared, and a month later the eyes had returned to the same state as they were in before the operation was performed. Therefore, although in this case the immediate effects were extremely favorable for a few days, the permanent result of the operation for the curc of the glaucoma was *nil*. The central origin of chronic glaucoma may be a fact, but if it is so, the removal of the superior cervical ganglion apparently does not interrupt the connection with the eye. Either the connection is not by this route or some other means of communication is established very soon after the resection of the ganglion.

The Elimination of Arsenic through the Hair and its Relation to Arsenical Poisoning. By E. Knecht, Ph. D., and W. F. Dearden, M. R. C. S.—Samples of hair taken from six people (males) were submitted to analysis. Two samples were from well-marked cases of arsenical beer poisoning, another from a patient who had been taking one ninth of a grain of arsenic a day for a long time, and three from healthy individuals. In the first three, arsenic was found to be present in the proportions of from 0.3 to 1. in 10,000. Arsenic was also found in the hair of the healthy individuals, but in the most minute quantities. The estimation of arsenic in the hair may prove to be of immense value in medico-legal cases, especially in the case of exhumed bodies, as the hair is one of the last parts of the body to decompose. The method employed was Sanger's modification of the Marsh test.

A Short Account of a Fatal Case of Laryngeal Diphtheria Complicating Measles. By G. J. Maguire, M. B.—The author reports the case of an infant, aged eighteen months, suffering from measles, who suddenly developed laryngeal stenosis leading to suffocation. Tracheotomy was performed, but to no purpose. No membrane could be seen. At the autopsy, however, the larynx was found to be almost occluded by a thick, diphtheritic membrane, cultures from which showed the presence of the diphtheria bacillus. Had there been no post-mortem examination in this case it would have escaped recognition and a focus of infection would not have been notified to the local health authorities.

British Medical Journal, March 16, 1901.

The Causation of Cancerous and other New Growths. By Dr. J. G. Adami.—In this article the author discusses the various theories as to the causation of new growths and their classification, and advances a theory of his own. The main arguments in favor of the parasitic origin and infectious nature of malignant growths are as follows: 1. The increase in frequency in malignant tumors in civilized communities during the last eighty years is out of proportion to the possible action of any factor, save the gradual spread of some infective agent. 2. The incidence of the disease is frequently found to be localized to certain villages, and even to certain houses. 3. The lesions produced by the growth of malignant tumors within the organism are comparable with those induced by certain known infective agencies, and a close analogy can be drawn between the tubercle and the dissemination of tuberculosis, and the primary cancer nodule and the metastatic cancers or sarcomatous growths. 4. In a large proportion of cases certain intracellular and extracellular bodies are to be recognized, which are most numerous in the young growing edge of the tumors. 5. In rare cases the experimental inoculation of fresh cancer material from one individual to another has succeeded.

Although there are objections to each of these arguments, yet the author favors the parasitic theory. The strongest objection to the old cell "rest" theory is that, while the misplaced cells may be a predisposing cause of tumor formation, they cannot be the primary cause. Some change in the surrounding conditions is demanded. But, whatever the origin of the tumor proper, however it is started, whether by a parasite or from a cell "rest," what makes the tumor is the assumption by the primary cells of that tumor of the habit of growth in place of the habit of work, and, according to the extent of this replacement, so do we get the various grades of

tumor formation from the most benign to the most malignant. The author carefully sums up the various points brought forward, one after the other, in arriving at this conclusion. According to this theory, microbes and their products may be one of the causes originating localized cell proliferation in the first place, provided that (1) they bring about stimulation rather than irritation, or irritation of so mild a type that the cells are stimulated to increased metabolism which does not go on to degeneration; and (2) provided that the microbes and their products continue in action for a sufficiently long time to set up the habit of growth. According to the stage of cell development in which this habit becomes impressed upon the cell, so do we have the various grades of benign and malignant tumor formation. But this continuance and persistence of microbial action must not be regarded as essential. If microbes do originate malignant tumors, they do not continue in the living state. Once the habit of growth is acquired, the presence of the microbe is no longer needed. According to the author, the line of research which promises the surest results in the future lies in the direction of testing various methods of arresting the growth of the tumor cells without injury to the organism in general, a work such as has been so ably initiated by Coley in this country.

On the Occurrence of Pyrexia in Cancer and other Diseases of the Liver, and in Cases of Gall-stone. By Dr. C. O. Hawthorne.—The author discusses the occurrence of fever in cancer of the liver, and calls attention to the fact that pyrexia does not necessarily mean the presence of any complication. There are cases of cancer with accompanying pyrexia in which no complication can be discovered after death, and, on the other hand, it is common to find in the neighborhood of a cancerous liver inflammatory changes of the existence of which during life there was entire absence of specific evidence. The pyrexia may be distinctly intermittent and preceded by a sharp rigor, suggesting the "intermittent hepatic fever" of Charcot; it should be remembered that Charcot does not confine the occurrence of this intermittent fever to cases of gall-stone. A combination of jaundice, intermittent fever, and hepatic enlargement demands very careful consideration before deciding on gall-stone on the one hand, or malignant disease on the other. Pyrexia also occurs in abscess or hydatid cyst of the liver, and has been noted in cases of cirrhosis of that organ, even when of the atrophic or multilobular type.

Digestion Leucocytosis in Cancer of the Stomach. By Dr. C. Douglas.—The author has studied the occurrence of digestion leucocytosis in cancer of the stomach. It has been stated by several observers that the normal increase in the number of the leucocytes during the digestion of a meal does not occur in cancer of the stomach. The author found that in eleven cases of cancer of the stomach digestion leucocytosis was absent in only six (54.5 per cent.), while it was well marked in four (36.3 per cent.), and inconstant in one (9.1 per cent.). He concludes that digestion leucocytosis essentially depends on the digestive and absorptive powers of the stomach, and that it may or may not occur in cancer of the organ, according to the degree of impairment of its functions.

The Palliative Treatment of Carcinoma Uteri. By G. R. Leighton, M. B.—The author reports a case of inoperable cancer of the uterus, in which large doses of opium were given for the purpose of prolonging life and relieving pain. The tincture of opium was used, and

the patient gradually worked up to eight ounces, or 264 grains of opium, a day; on some days twelve ounces, or nearly 400 grains of opium, were taken. The patient's condition was improved in every way, and her life was prolonged at least two years. Throughout the whole of the last two years there was no difficulty with the bowels, no head symptoms, and a plain milk diet was well taken.

The Application of Romanowsky's Stain in Malaria. By W. B. Leishman, M. B.—The effects produced by Romanowsky's staining are due to a red dye which is extracted from alkaline solutions of certain kinds of methylene-blue, when to such a solution is added a small quantity of a very weak watery solution of eosin. Its great value as a differential stain for the malarial parasite lies in its intense affinity for nuclear chromatin. Two solutions are necessary. A. A one-per-cent. solution of "medicinal" methylene-blue in distilled water, rendered alkaline by the addition of 0.5 per cent. of sodium carbonate. This should stand in a warm room for some days before using. B. A 1:1,000 solution in distilled water of "Eosin extra B. A." These stock solutions will keep indefinitely. For use, each solution must be further diluted with distilled water in a proportion of one to twenty-five, and an equal volume of each diluted solution is poured on the coverglass specimen of blood in such a way that they come in contact with the film at the moment of mixing. The specimen is left in the stain for from half an hour to an hour; it is then decolorized in absolute alcohol for two seconds, washed in water, dried, and mounted. Or, instead of using alcohol, the specimens may be decolorized by leaving them in running water for some time. The red corpuscles will be found to be colorless, while the nuclei of the leucocytes and the blood plates will be stained a ruby-red. Should malarial parasites be present, they will be readily recognized; their bodies are stained blue, their nuclei ruby-red. The ring forms can be recognized with the greatest ease. The stain has a specific action upon the red corpuscles infected by tertian parasites. Bright red dots or points appear throughout such an infected cell (Schüffner's points). By the use of this stain, mixed infection with different varieties of malarial parasite is readily diagnosed. The article is accompanied by a colored plate which shows clearly and beautifully the appearance of malarial parasites stained by Romanowsky's method.

The Influence of the Dwelling upon Health. By Dr. J. F. J. Sykes.—The third of the Milroy lectures upon this subject.

March 23, 1901.

The Diagnosis and Treatment of Intussusception. By C. P. B. Clubbe.—The onset of intussusception in children is nearly always sudden, being manifested by an attack of pain, followed by vomiting. A natural stool is usually passed soon after the first attack of pain. The attacks of pain become more frequent, and within a few hours some blood is passed by the bowel. The pulse rate and temperature are usually normal. Examination of the abdomen discloses the presence of a sausage-shaped tumor, in the line of the colon. Should the abdomen be too resistant for a satisfactory examination, chloroform should always be given. In some cases the intussusception may protrude through the anus, and be mistaken for a prolapsed rectum. Intussusception may occur during an attack of diarrhoea and a diagnosis of dysentery be made, based on the presence of blood and slime in the movements. The author believes injections to be a useful and safe mode of treatment: in eight per cent. of his

cases, they have brought about a cure. The injections may be given by means of an ordinary enema syringe or an irrigator, and may consist of warm oil and water. An anæsthetic should be given, the buttocks raised, and from ten ounces to one pint of fluid injected. Should the tumor have disappeared, a minute dose of morphine should be given, and the child put to bed. If there is no return of the symptoms in forty-eight hours, the case may be considered cured. If there is any return of the tumor within that time, proceed at once to the operation. When the tumor is small and in the line of the ascending colon, incise to the right of the rectus muscle. In other cases the incision should be in the middle line. Deliver the tumor through the incision, and, by squeezing from below, force out the intussusciptions. Do not attempt to pull out the entering bowel. Where reduction is impossible, the gut must be resected. After the intestines have been returned, close the bowel with through-and-through silkworm-gut sutures. These should never be removed before the tenth day.

Autoreduction of Hernia "En Masse" as a Cause of Abdominal Obstruction. By W. J. Walsham, F. R. C. S.—In this communication the author calls attention to a cause of abdominal obstruction which has hitherto received little consideration—*i. e.*, where the patient has reduced the hernia himself *en masse*, and has then come under notice as suffering from obstruction. During the past few years the author has met with seven such cases, three of which are reported in this article. An early diagnosis is of the greatest importance. Given an accurate diagnosis and early surgical intervention before the integrity of the intestinal wall has been seriously affected, the strangulated gut can be at once cut down upon, the operation can be quickly completed with very little disturbance of the abdominal contents, and with almost a certainty of success, whereas the reverse would probably be the case if the diagnosis was only made during a prolonged exploration attended by free manipulation of the intestines and consequent general implication of the peritoneal cavity.

Some Practical Points in the Diagnosis and Operative Treatment of Perforated Gastric Ulcer. By R. C. B. Maunsell, M. B.—The points in reference to diagnosis to which the author draws attention are: 1. The pain, which begins in the epigastrium, spreads, but does not shift its position. 2. There is no pain on micturition, which is a frequent sign in peritonitis of the lower abdomen. 3. Thirst is not intense, and there is no tossing about, as in hæmorrhage. 4. There may be no distention in muscular subjects, the tympanites and free gas being only shown by the encroachment on the thoracic area. 5. The pulse cannot be relied upon in forming an early diagnosis. 6. The statement sometimes made that a "stomach note" excludes perforation is unwarrantable, as a perforated and a collapsed stomach are by no means synonymous terms. 7. Liver dullness is diminished or absent in almost every case. The best time for an operation is as soon after the diagnosis as it can be methodically undertaken. It is never too late to operate unless the patient is moribund. The important part of the operation is the cleansing of the peritoneal cavity. The author douches first, and then carefully wipes out the pelvis, superior surface of the liver, and inferior surface of the diaphragm with large gauze pads held in the hand. Through-and-through fishing-gut sutures should be used to close the abdomen, as they exert no capillary action between the non-aseptic peritoneal cavity and the wound.

A Case of Hour-glass Stomach: Non-malignant; Gastro-enterostomy. By C. P. Childe, F. R. C. S.—The

author reports the case of a woman, aged fifty-one years, upon whom he performed a gastro-enterostomy, thinking the case to be one of malignant disease of the pylorus. The patient sank steadily after the operation and died on the fifth day. At the autopsy, the case was found to be one of hour-glass stomach, due to cicatricial contraction of an ulcer of the stomach situated near the pylorus. At the operation the jejunum was stitched to the second or distal compartment, thus failing to benefit the condition of things in the slightest.

Ulcer of the Stomach; Acute Hæmatemesis; Gastrotomy; Arrest of Hæmorrhage at the Bleeding Spot; Venous Thrombosis in both Legs; Recovery. By H. B. Angus, M. B.—The author reports the case of a woman, aged nineteen years, the salient points of which are covered in the title of the article. There are two classes of such cases which demand surgical aid: (1) When hæmatemesis is often repeated until it is threatening life; (2) copious recurrent arterial hæmorrhage. The venous thrombosis in the saphenous veins of both limbs was not considered to be of septic origin, the constitutional disturbance being slight and there being no pus formation.

A Case of Gastric Fistula; Operation; Death. By C. F. M. Althorp, M. B.—The author reports a case in which he attempted to close a gastric fistula. The patient developed pneumonia and died on the sixth day. At the autopsy the wound in the stomach was found to be infected, and showed no attempt at healing.

Perforated Ulcer of the Stomach. By W. H. Horrocks, M. B.—The points of interest in the case here reported are: 1. The absence of any indication of gastric ulcer before perforation. Latent ulcers of the stomach are generally situated near the cardiac end, and close to the lesser curvature. 2. The absence of any apparent exciting cause for perforation. 3. The pain and tenderness correctly localized the position of the ulcer, and the marked tension of the abdominal wall at this part made the diagnosis more certain. 4. The repeated movements of the patient spread the extravasated material over the whole abdomen. 5. The cleansing power of the peritonæum over its lower zone was markedly shown.

A Case of Subphrenic Abscess; Operation; Recovery. By Dr. H. J. Campbell and Dr. T. J. Wood.

Four Cases in which the Murphy Button was Used. By G. P. Newbolt, F. R. C. S.—The author has used the Murphy button in four cases. In three of these the result was all that could be desired; in the fourth case (one of intussusception in a boy aged four years) the patient died within twelve hours of the operation. In each instance Lembert sutures were used over the button, relieving the tension of that part of the intestine.

A Case of Acute Intestinal Obstruction Due to a Papillomatous Ovarian Cyst and a Carcinoma of Small Intestine, Treated by Ovariectomy and Enterectomy; Recovery. By H. Savory, M. B., and W. G. Nash, F. R. C. S.

Case of Extreme Stenosis of the Small Intestine in an Infant. By Dr. E. W. H. Groves.—Chronic intestinal obstruction in an infant, apart from peritonitis or intussusception, is extremely rare, so that the case here reported is of great interest. The stenosed area of the ileum was three quarters of an inch long and admitted a probe with the greatest difficulty. The jejunum and part of the ileum were much dilated. The condition was almost certainly congenital. The child practically died of starvation.

Notes on the Anatomy and Surgery of Meckel's Diverticulum. By G. A. Clarkson, F. R. C. S.

Diseases and Disorders of the Heart and Arteries in Middle and Advanced Life. By Dr. J. M. Bruce.—The second of the Lettsomian lectures upon this subject.

Gazette hebdomadaire de médecine et de chirurgie,
March 10, 1901.

Dementia of Puberty.—M. Paul Lerieux, in a review of the subject, says that the dementia of adolescence must be ascribed to cortical lesions which are due to some form of self-intoxication, probably of sexual origin. The author thinks that the thyroid extract should be tried as a remedy. [The article is merely a résumé of authoritative writings on the subject.]

Clinical Study of Deciduoma Malignum.—M. G. Métoz, in his thesis, reviews the ætiology, pathogenesis, symptoms, and treatment. The examination of a patient who complains of hæmorrhages, he says, should exclude epithelioma of the cervix, submucous fibroids, and metritis, other diseases having been eliminated. A careful intra-uterine examination should follow, and a microscopic study of removed *débris* should be made. Curettage, followed by applications of zinc chloride, should first be done. If bleeding continues and new foci of disease can be demonstrated, hysterectomy should be performed without delay.

Wiener klinische Rundschau, March 10, 1901.

Unusual Case of Adrenal Tumor.—Dr. A. Schittenhelm reports the case of a man who died of a medullary carcinoma of both adrenal bodies. He presented no symptoms beyond a dull pain in the back, cachexia, and increasing weakness. None of the usual signs of adrenal disease were present. Five days before death, however, the patient was seized with violent cough with expectoration, severe diarrhœa, and high but irregular temperature. Numerous metastases were found in different organs.

Toxicity of Expired Air. By Dr. Emanuel Formanek. (*Continued article.*)

Pyloric Spasm in Infants. By Dr. A. Köppen. (*Continued article.*)

Centralblatt für Chirurgie, March 16 and 23, 1901.

Study of Röntgen Plates.—Dr. K. Ludloff recommends the use of an opera glass at a distance of from three to ten feet from the Röntgen plate. The picture upon it becomes intensely more distinct in all its details. Much will be seen which will escape ordinary vision.

Morphine Before Ether.—Dr. W. Reinhardt uses one hundredth of a grain of atropine combined with one third of a grain of morphine, subcutaneously, one hour before the administration of ether. It aids in the narcosis, and the atropine is at the same time a cardiac and respiratory stimulant. No bad effects were observed and the secretion of mucus during anæsthesia has been decidedly diminished.

Benzine in Surgery.—Dr. Felix Franke uses benzine in preference to ether for the removal of fat or grease from the skin. It is cheaper, it does not cool the skin as disagreeably as ether does, and is never painful, even when applied over inflamed surfaces or in open wounds. The odor is occasionally disagreeable, but this is its only drawback.

Technics of Apply Splints. By Dr. Ferdinand Bähr.

Centralblatt für Gynäkologie, March 9 and 16, 1901.

Two Cases of Hæmatoma of the Abdominal Wall during Pregnancy.—Dr. W. Stœckel reports these cases, in which, without violence or injury of any kind, hæmatomata developed in the layers of the abdominal wall. In one case the right epigastric artery was the source of hæmorrhage; in the second, the anastomotic network between the superior and inferior epigastric arteries.

The Control of Sterilizing Apparatus. By Dr. Sticher.

Remarks on the Disinfection of the Hands. By Dr. P. Strassmann.

Riforma medica, February 14 and 15, 1901.

The Spectroscopic Appearances of Blood Charged with Carbonic Oxide and Allowed to Decompose. By Dr. Carlo Raimondi.—The spectroscopic appearances of blood charged with carbonic oxide and allowed to decompose are different from those observed in normal blood. Carbo-oxyhæmoglobin is very resistant. It may be identified when hæmoglobin and hæmatin are decomposed and show only traces of recognizable residue. The recognition of this fact is important, from a medicolegal point of view, in cases of suspected carbonic oxide poisoning. A future paper will be devoted to the consideration of the appearances of the blood in different stages of decomposition.

February 16, 18, and 19, 1901.

Concerning Secondary Meningitis following Lobar Pneumonia. By Dr. Giuseppe Pollaci.—The author has found four cases of meningitis in fifty-five autopsies on persons affected with lobar pneumonia in the years from 1880 to 1896. A study of these cases has enabled him to draw the following conclusions: A diagnosis of meningitis complicating lobar pneumonia cannot be made when only one or two of the symptoms that indicate an inflammatory involvement of the brain membranes are present; but if the case presents the symptom-complex of meningitis in its entirety, there is no doubt that a meningeal inflammation exists. We must remember that cerebral symptoms may be due to the toxins of pneumonia, and not to the meningitis.

Vratch, February 10, 1901 (*February 22, New Style*).

Concerning Diseases of the Cerebellum. By Dr. P. I. Schatiloff.—The clinical localization of lesions in the central nervous system is still very imperfectly worked out, in spite of recent advances. This is especially the case with diseases of the cerebellum, for very often the clinician must content himself with vague statements concerning the nature and location of the lesions, as the disease frequently runs its course without any symptoms of importance. The author, therefore, considers it wise to review the modern data of cerebellar physiology before reporting his case. (*To be continued.*)

On the Affections of the Upper Respiratory Passages in Rheumatism. By Dr. E. B. Blumenau.—Attention was called to the connection between affections of the throat and acute articular rheumatism as early as 1855 by Trousseau, and by Clark and Ogle. A commission appointed by the British Medical Association in 1885 found that an inflammation of the tonsils precedes acute articular rheumatism in almost twenty-five per cent. of all cases, and, since then, the publication of numerous cases of this kind leaves no doubt that there is a clinical

form of amygdalitis that deserves the designation "rheumatic sore throat." It is well known that the tonsils are an avenue of entry for a number of various bacterial poisons, as that of scarlatina, diphtheria, etc.; but as the bacterial cause, if any, of rheumatism is still unknown, the relation between rheumatism and amygdalitis is not quite clear. It is possible, however, that the germs of putrefaction and the diplococcus of Fraenkel which are found in the secretions of inflamed tonsils may have something to do both with the amygdalitis and the rheumatism. Yet one cannot say with certainty that the various inflammations of the joints that are described as rheumatism are really one affection, for even the fact that the salicylates do not prove efficient in every case of rheumatism shows that there must be various causes at the back of these joint affections. There is no doubt, however, as to the clinical and ætiological connection between certain cases of amygdalitis and acute articular rheumatism. The tonsils are presumably the place of entrance of the rheumatic poison. The author examined twenty patients with acute articular rheumatism on the first day of their entrance into the hospital, and found that a sore throat had been present in three of these before the onset of the joint pain. In addition, he reports three cases in which there had been amygdalitis, followed by rheumatism, one case of inflammation of the cricoarytenoid articulation due to rheumatism, and one case of inflammation of this joint due to influenza followed by typhoid fever.

On the Physiology and Pathology of the Interventricular Sæptum. Syphilis of the Interventricular Sæptum. By Dr. M. J. Breitman.—No text-book on physiology speaks of the function of the interventricular sæptum in the contraction of the heart, and it is impossible to remove a portion of the sæptum for experimental purposes. This experiment is performed for us in a very striking manner by syphilis. A gumma may develop in the sæptum, or cicatricial changes may occur in it, while the rest of the heart may remain perfectly normal. The altered sæptum ceases to functionate properly, and the activity of the heart undergoes certain changes which can only be referred to these lesions in the sæptum. The clinical symptoms of syphilitic sæptum are identical, whether there is a gumma or a cicatricial process, except that they are more marked because the area affected is greater. Alterations in the sæptum may not give rise to any symptoms, and may cause sudden death in apparent good health. The effect of these changes is always an interference with the contractions of both halves of the heart muscle, leading in fatal cases to failure of the heart's action. In cases in which such changes in the sæptum give rise to symptoms, there is a well-defined clinical picture. In very rare instances the whole heart muscle is interfered with as a result of changes in the sæptum, and this indicates that in some way the lesion has affected the nerves of the heart. Such cases are characterized by irregular pulse, brachycardia or tachycardia, præcordial anxiety, and attacks of syncope. As a general rule, changes in the sæptum affect the right ventricle before the left is influenced, because the former is the weaker of the two halves. In such cases dyspnoea is a prominent symptom. The symptoms of perforation of the sæptum are the same as those of patent foramen ovale, and therefore need not occupy us here. As regards the effect of syphilitic changes in the auricles, it is probable that they correspond to the results of changes in the ventricles, although they are less marked.

Hydrorrhœa Nasalis. By Dr. A. F. Eckert (*continued*).—The disease in question is quite rare, Bos-

worth having collected only eighteen cases in 1889, including two of his own. Since then, the clinical reports published bring the number of cases on record to forty-two. The symptomatology of these cases is not at all uniform, the only symptom that is present in all cases being the discharge of watery fluid from the nose. An entire series of these cases presents cerebral symptoms of a severe character, and the author's case, therefore, cannot be classed with these. In others, a fracture of the base of the skull was found at the autopsy. According to Freudenthal, the source of the serous fluid cannot be readily determined without a chemical analysis, and such an analysis showed in his case that the fluid was of cerebrospinal origin. In the author's case the chemical characters of the fluid did not correspond to those of cerebral fluid, for it did not contain any sugar. In Freudenthal's case the fluid was observed to escape between the nasal sæptum and the middle turbinal bone, just as in the author's case. There is no doubt that, in the cases recorded, the sources of the fluid were widely different, although in all the discharge escaped from the nose. The connection between cough and hydrorrhœa nasalis is not quite clear. The treatment consists in the use of cocaine, the application of the constant electric current, the local use of aristol, and the administration of strychnine and atropine, as well as attention to general health.

Letters to the Editor.

ELECTRICITY IN GOÎTRE.

241 WELLESLEY STREET, TORONTO, March 5, 1901.

To the Editor of the *New York Medical Journal*:

SIR: In your issue of February 23d I notice a communication from Dr. Jehiel Lefler in reference to a case of sudden death in goître under electrical treatment, reported by me in the October number of the *Canada Lancet*. Had Dr. Lefler, before reviewing the article in question and criticizing the treatment adopted, taken the care to read the original article, he would not have displayed the lack of knowledge of the facts of the case which his letter indicates. In the beginning, he digresses somewhat to mention his own uniformly satisfactory results in the treatment of exophthalmic goître, stating, however, that in order to obtain the best results possible and to be positively free from any and all danger, a properly selected instrument and a competent electrician are absolutely and positively essential, thus making the quite unwarranted assumption that these requisites were wanting in the case under discussion; hence the fatal result. Briefly, I should like to correct some of the doctor's mistakes or misapprehensions. In the first place, the case was not one of exophthalmic goître, but one of ordinary colloid goître, without the symptoms of Graves's disease, and was so reported; consequently, his discussion of the increased dangers in the electrical treatment of that disease is quite foreign to the case reported.

The instrument used was a Waite and Bartlett apparatus—battery, controller, and meter—the one used in the Toronto General Hospital. That the treatment was carried out with skill and care, I think that the name of the electrician who operated in the case is a sufficient guarantee, Dr. C. R. Dickson, a past president of the American Electrotherapeutic Association, and electrician to four different hospitals in Toronto. If electricity had anything to do with the fatal issue in this case, I think we may fairly assume that it was not due to

any fault or lack of skill in technique on the part of the operator or to an unsuitable apparatus.

Dr. Lefler's opinion as to the cause of death is precisely the same as the one expressed by me in the autopsy report—irritation of the recurrent laryngeal nerve with spasm of the glottis and consequent asphyxia.

It is scarcely necessary for me to say that I am quite in accord with the doctor as to the necessity for skill and care in the use of electricity in these cases. It is well to bear in mind, however, that sudden death in goître, apart from any treatment, occasionally occurs, either from direct pressure on the trachea or on other important structures in the neck, and in the case reported by me the patient had nearly died on a previous occasion in an attack that came on without any evident exciting cause, much in the same way as the one that ended fatally.

In conclusion, Dr. Lefler is to be congratulated on the uniformly happy results he has had in the use of electricity in the treatment of exophthalmic goître, an experience very different, I am sure, from that of most clinicians who have tried this agent.

H. B. ANDERSON, M. D.

SEXUAL INTEMPERANCE.

LEAVENWORTH, KANSAS, March 20, 1901.

To the Editor of the *New York Medical Journal*:

SIR: Truth comes to us in fragments. We have lately received pieces—or solid chunks—of it from Dr. Drennan on the above-mentioned subject.

In your issue of February 16th her critics have also given us bits of truth. It seems now to be generally admitted, even by the theologians, that the doctrines of evolution are true. The special training and experience of the medical fraternity would seem to lead it irresistibly to the adoption of evolution as the very cornerstone of the physician's foundations of thought and belief. Nevertheless, when theological views coincide with the facts of science, as a part of Dr. Rose's quotations prove they sometimes do—the medical profession should give them a cordial and grateful reception. Dr. Talmey's contention that man is not the only male animal who abuses himself and his female can be shown to be true. Instances of the abuse of the female would be much more common but for the fact that such female is endowed by Nature with more adequate physical means of defending itself, as compared with the human female, against the undesired embraces of the male. The human female must appeal to a higher court—the moral nature of her companion—although too often her appeal is unheeded. But to the statement that animals live in polygamy, there are many exceptions, as witness the class of birds, excepting the rasorial or gallinaceous. Then, too, many species have a season specially devoted to procreation, as in the *Cervidæ* and *Phocidæ*. All the lower animals seem to be largely under the influence of this law, except as modified by artificial environment. No doubt it is true that thousands of women, each of whom gives birth to a child every year for several successive years, may be found who enjoy good health. It is equally true that thousands of women miscarry for several successive years and yet retain good health. Still, these results for both classes are the exception and not the rule. It is also true that thousands of women are crushed, mentally and physically, by too frequent parturition, the children which they bring forth in dread and sorrow inheriting more or less the acquired infirmities of their mothers. Beecher said: "If a man

is born right at first, he does not need to be born again, and to be born right you must begin with his grandfather."

In the opinion of your correspondent the main arguments of Dr. Drennan have not been weakened by her critics. There is one lesson that every one must learn—the great lesson of self-control. It is often difficult, but no one is safe, morally or physically, until he has thoroughly learned it. He who considers the pleasure of sexual intercourse as primary, and procreation as secondary, is never satisfied. There is "no bottom to the cistern of his lust." Like begets like. If parents wish their children to have the virtue of self-control, they must first learn to practise it themselves. Perhaps it is true that the majority of men in the prime of life could not be induced to totally abstain from sexual intercourse during those periods when the wife usually has a feeling of repugnance to the sexual act. So much the worse for the men, their wives, and their children. "He is a free man whom the truth makes free, and all are slaves besides."

WALTER F. MORGAN, M. D.

INCONTINENCE OF URINE AND CLITORIDECTOMY.

20 WEST FORTY-FIFTH STREET,
NEW YORK, March 26, 1901.

To the Editor of the *New York Medical Journal*:

SIR: I notice in your issue of March 23d an editorial on Extirpation of the Clitoris for Incontinence of Urine, incited by a recent report of such an operation by a French surgeon on a woman twenty-eight years of age, the removal of the almost constantly erect clitoris being at once followed by a complete cure of the urinary incontinence. You conclude your editorial by saying, very properly, that "some indication is desirable before an epidemic of clitoridectomies for enuresis sets in." The French surgeon's experience is not unique, for his case reminds me of a similar one in which I performed the same operation for the same urinary condition, with the same favorable result, some years ago.

A girl, fifteen years of age, was admitted to my service at Mount Sinai Hospital for complete urinary incontinence, the cause of which was unknown. The girl's behavior and peculiar facial expression, as well as the congested appearance of the external genitals, especially the clitoris, aroused in me the suspicion that masturbation might be the cause of the enuresis. I therefore caused her to be watched, and she was detected by the nurse several times in the act of masturbation. As it was impossible to restrain her from this act without putting her in a strait-jacket, and as the enlarged and turgid clitoris showed that the practice had been indulged in for some time, I decided to try the experiment of removing the clitoris, feeling that this was justifiable under the circumstances, especially if the result was favorable, and that, even if unfavorable, I need not fear the fate of Baker Brown, of London, who, it may be remembered, some forty years ago, was expelled from the London Obstetrical Society for removing the clitoris of several young women who suffered from nymphomania. Fortunately, we have progressed in many ways during the last forty years, and medical men are no longer ostracized for performing operations which offer a reasonable chance of success, however problematical they may appear to be at first.

I removed not only the clitoris, but also the labia minora, which were much hypertrophied, and the girl at

once regained control of her bladder. Before she left the hospital, completely cured of the enuresis, her altered behavior and facial expression, due to the cessation of masturbation, were plainly noticeable. She remained under observation for about a year, and continued in perfect health. Of course, I do not mean to advise clitoridectomy for enuresis unless it is fairly evident that the irritation of the clitoris by masturbation or disease is the cause of the urinary incontinence.

PAUL F. MUNDÉ, M. D.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

Meeting of March 7, 1901.

The Vice-president, Dr. CHARLES L. DANA, in the Chair.

Alcohol as a Food.—The VICE-PRESIDENT introduced the topic for discussion by referring to the need of hearing more of the scientific aspect of this question and less of the purely sentimental side. He said that in his personal study of about 350 cases of alcoholism in Bellevue Hospital he had noted that over two thirds of this number had begun drinking before the age of twenty, and that the habitual drunkard could not stand, on the average, more than about fifteen years of such life, or about 3,000 intoxications, before the system succumbed.

Dr. HERMANN M. BIGGS pointed out that the type of drinking had changed in recent years, for, whereas in the early years of his service in Bellevue Hospital there had been much cirrhosis of the liver and a common history of free indulgence in spirits, at the present time the vast majority of the alcoholic patients gave a history of taking from one to three drinks of whiskey a day and of four or five pints of beer. This change in the habit of drinking had been associated with an alteration in the character of the lesions. Cirrhosis of the liver had gradually given place to such degenerative effects as disease of the heart, blood-vessels, and kidneys. A search through the records of the health department had shown that in the last twenty years there had been but slight increase in the death rate from alcoholism, hepatitis, and hepatic cirrhosis, in spite of the large additions to the population, while in this period there had been an increase of almost 150 per cent. in the deaths from disease of the heart and vessels, with a striking augmentation of the number of deaths from kidney disease. And this was true not of our country alone. During the same period lager beer had largely replaced the weiss beer formerly consumed in Germany, and this change had been associated with a very large increase in the number of deaths from disease of the kidneys.

Dr. M. ALLEN STARR commented upon the very different effects of whiskey, brandy, and gin on the individual, and instanced this as proof that the physician, in his study of alcoholism, must bear in mind that he was not dealing with the effects of alcohol *per se*, but with the effects of this agent in certain combinations. Alcohol seemed to affect the parts of the brain which were the most highly organized, the lower centres of the brain and spinal cord not being apparently susceptible to its influence. Berkeley had shown that alcohol acted on the brain by dissolving, as it were, the dendrites, and

so rendering the cells incapable of receiving impulses from other cells. Speaking of the care and treatment of inebriates, Dr. Starr said that it was not very common to find a recovery from chronic alcoholism in the form known as periodical drinking—*i. e.*, where there was a complete cessation of the drinking in the interval. These cases were examples of moral obliquity rather than of true insanity. He was of the opinion that moral suasion was often more potent in such cases than medicinal treatment. As these individuals were neurasthenic, if their neurasthenia could be relieved, their ability to resist the drink-craving would be correspondingly augmented. The only reformed drunkards of whom he had knowledge had been saved, not by medical, but by religious influence. An effort should be made to secure the legal commitment of chronic alcoholics to institutions in which they could be prevented from procuring liquor.

Dr. ALEXANDER LAMBERT said that, of the 24,300 patients admitted to Bellevue Hospital last year, over twenty-five per cent. had been in the alcoholic wards. He had tried the experiment last summer of threatening the "repeaters" with the workhouse if they were again admitted to the alcoholic ward, and this had had the effect of reducing the average number of this class for the next six weeks from sixty to twelve. As soon as these persons had discovered that this was only a threat, and was not to be put into execution, the number of such admissions had quickly risen to the former figure. It seemed to him that the outlook from treatment must be discouraging, unless we had some law permitting the detention of the alcoholic subject until he was sufficiently recovered to allow of his safe discharge from custody. Statistics were then quoted to show the enormous number of defective and diseased children among the progeny of alcoholic parents.

Dr. JAMES EWING said that he had been studying the effects of alcohol on the ganglion cells. On gross examination, the brain of one who had died of delirium tremens presented a characteristically marked venous engorgement, and Nissl's or Golgi's stain revealed changes apparently identical with those produced by sunstroke, tetanus, and rabies. There was a complete disappearance of the chromatophilous bodies, and the distribution of the lesions pointed to a general circulating poison as the cause. As a rule, the spinal cord did not exhibit such marked lesions as the ganglion cells in the cortex of the brain. Certain experiments on the lower animals, while failing to produce delirium tremens because of the alcohol acting as a fatal irritant, still, apparently, justified the deduction that alcohol acted chiefly on the more highly organized cells of the nervous system. In the brain of the chronic alcoholic were found evidences of wear and tear in the presence of large deposits of pigment in the ganglion cells.

Dr. JOSEPH COLLINS discussed the subject of *The Law and the Inebriate*. He quoted extensively from the laws of various countries regarding the habitual inebriate, and insisted that this class of persons could be effectually reached only by legislation. Legislation of this order had been desultory and entirely unsatisfactory in our own country; it had been of a fairly effective kind in most of the provinces of Canada, while New Zealand and Switzerland had led the world in this very important matter.

Dr. S. A. KNOPF called attention to the important part played by alcoholism in the production of tuberculosis. He averred that statistics proved that twenty-five per cent. of children committed to sanatoria for the

treatment of tuberculous diseases were the offspring of alcoholic individuals. It was a prevalent but erroneous opinion that alcohol was a very useful agent in the treatment of consumption. If given in sufficiently large doses to control the temperature, it would make the patient a confirmed alcoholic. For the treatment of inebriates, he would depend upon moral suasion and hypnotic suggestion. Poor tenements and poor cooking, such as was practised by the tenement-house population, were largely responsible for alcoholism.

Dr. GEORGE L. PEABODY said that he agreed with Dr. Knopf regarding the last point made, and he also thought that ignorance of the effects of alcohol, even among otherwise well-informed persons, was an important factor in the production of alcoholism. In these days of working under great pressure, the fatigue experienced at the close of the day was a strong temptation to indulgence in alcoholic drinks. It should be known and appreciated that most of the so-called "biters" on the market contained from forty to fifty per cent. of alcohol. Ladies were often led into taking sherry wine simply because it was called a wine, when in reality it was a spirit, containing from thirty to forty-five per cent. of alcohol. The speaker then referred to the "gold cures," and said that he had been informed by a physician who had been in one of these institutions that it was the practice in places of this class to give daily hypodermic injections of a golden-colored liquid which contained strychnine and atropine, but no gold. After this treatment had been continued for a certain length of time the patient was told that the desire for liquor had been largely controlled, and that he could help himself to some liquor in the presence of the physician if he desired to satisfy himself of the truth of the contention that the treatment employed had produced such an effect on his system that liquor would no longer agree with him. Those who accepted this invitation, from whatever motive, were then given what they supposed to be the regular hypodermic injection of "gold solution," but, as a matter of fact, a good dose of apomorphine had been smuggled into the solution. The effect of such treatment, both physical and mental, could easily be imagined.

Book Notices.

The Medical Examination for Life Insurance and its Associated Clinical Methods, with Chapters on the Insurance of Substandard Lives and Accident Insurance. By CHARLES LYMAN GREENE, M. D., Clinical Professor of Medicine and Physical Diagnosis in the University of Minnesota. With Ninety-nine Illustrations. Pp. xiv-9 to 426. Philadelphia: P. Blakiston's Son & Company, 1900. [Price, \$4.]

THOSE of us who look beneath the surface of things about us for the causes which underlie them must often have reflected upon the phenomenal growth in this country of the various forms of life insurance, mutual and stock companies, assessment and benefit societies.

To us the explanation is not difficult. Probably no race or nation of men has a keener sense of moral responsibility than our own, and none is less disposed to lay up wealth against a time of need. The American is fond of the comforts of life, and he is not willing to forego them for the benefit of those who succeed him, except in so far as is absolutely necessary to protect the helpless during their period of need. He believes that

his children should go out to battle with the world just as he has had to do, and, once they are started, his sense of responsibility for their success ceases. To our mind, the peculiar capacity of life insurance to afford protection during this period of helplessness is that which has made it so important and distinctive a part of our civilization, and, if our view is correct, we may expect that it will grow and increase in importance with the growth of our nation in population and in wealth.

But we, as practitioners, have much more than a philosophical interest in life insurance. It is the one great industry to the success of which the technical skill of the physician is an indispensable requisite, and from which the profession derives no inconsiderable portion of its revenues. It is therefore the one business in which physicians should have at least some training and for which they should, if possible, prepare themselves during their student days. Curiously, it is only recently that the medical schools have become alive to this need and have taken up examining for life insurance as a part of their proper work. From the standpoint of these reflections, the book which lies before us may be said truly to "fill a long-felt want." It is a text-book of life insurance for students and practitioners, and its author is to be congratulated upon the excellence of his work.

The book opens with a brief historical review of the business from the earliest times and an intelligent statement of the scientific foundations upon which it now rests—for the vague guesswork of a hundred years ago has been replaced by a definite knowledge of the laws of mortality among large numbers of men.

This opening chapter is very readable and should give the student a better grasp of the subject than he has ever had before. The succeeding chapters are devoted to an interesting discussion of the relations of the medical examiner to the agents and the companies, and especially to the applicants for insurance. The difference in the point of view of the physician toward his patient and toward the applicant for insurance is well described—and, to our mind, this is the very kernel of the subject. However well trained in his profession a physician may be, he is not a good medical examiner until he has acquired this point of view, and, on the other hand, if he has it, he may be a very good examiner even if his medical attainments are but scanty.

The other important branches of the subject, "a review of the questions usually asked in medical blank forms," "heredity," "occupation," "the rôle of inspection in physical diagnosis," "the examination of the chest and abdomen," and "the examination of urine," all are well treated of. It may be that a mistake has been made in the chapters on examinations of the heart and lungs in that they are too exhaustive. Fortunately, it is an error on the safe side. Our own idea is that physical diagnosis is a necessary part of the medical training of every physician, whether he studies life insurance or not, and he acquires his knowledge from his instructors in the class-room and the clinic and from special text-books on that subject. When, later in life, he wishes to learn over again any portion of the subject, he at once makes use of his old friends, the text-books of his student days. What he needs in a life insurance text-book is not a formal restatement of the entire subject, however thoroughly done, but rather a brief outline of the salient points of diagnosis—in short, he wants suggestions. We have not seen in many a day a book so full of suggestion, so reminiscent of the widest range of clinical experience, and we regret that that

tone was not introduced to the same extent into this single portion of the work. As we have already said, the fault, if fault it is, is on the side of too great thoroughness. Dr. Greene is evidently a careful student and teacher of diagnosis, and he has done his work so thoroughly that even this criticism may smack too much of captiousness.

In "the examination of urine" our author very sensibly avoids any reference to some of the more delicate tests for albumin, and very pertinently says that the essentials of a good test for albumin are "simplicity, a reasonable degree of delicacy, and decisiveness." Examiners will do well to follow his advice.

A chapter is devoted to "the insurance of substandard lives," a subject which is sure in the fulness of time to occupy a very large place in life insurance medicine and to tax more fully the resources of the practitioner than the present routine selection of standard lives. If a life is unexceptionable, it requires the exercise of but moderate skill to determine the facts and submit a record of them to the company interested; but, if it is impaired far beyond the limits of an average healthy life, only the nicest discrimination and the most mature judgment will suffice to place a proper valuation upon it. Until very recently our English cousins had this substandard field all to themselves. Within a few years, however, as Dr. Greene points out, one of the great American companies has undertaken to insure almost all types of impaired lives, and it seems to us that this position must sooner or later be adopted by life organizations generally. When this time does come, it is to be hoped that the standard of the profession in life insurance examining will be found to have advanced sufficiently to fully satisfy the demands of the business.

The book is well printed on good paper, has been carefully indexed, and is altogether an admirable exposition of the subject. It should be found in the library of every examiner for insurance.

Sexual Debility in Man. By F. R. STURGIS, M. D., formerly Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York, etc. Pp. 14 to 432. New York: E. B. Treat & Company, 1900. [Price, \$3.]

DR. STURGIS has written a most readable book; while it does not lack interest or spice, it is, nevertheless, scientific and deeply grounded. The work opens with three chapters on the anatomy and physiology of the male sexual organs. These are followed in turn by chapters on masturbation and onanism, spermatorrhœa, pollutions, prostaticorrhœa, sexual impotence, and sterility.

The author takes the view that masturbation is not followed by sequels of such dire consequence as have been generally preached and believed. While functional results are not rare, and even, in exceptional cases, more serious disturbances follow the habit, the general denunciation of masturbation is not agreed to by the author.

Spermatorrhœa he regards as a disease *sui generis*, and separates it distinctly from pollutions. The author does not share the groundless notion that spermatorrhœa leads inevitably to impotence and sexual uselessness.

The treatment of the various conditions considered is lucidly and fully given, and hopefulness mainly characterizes what he says. All measures are to be tried; none to be neglected, if necessary.

The book is most interesting and should have, as it no doubt will, a wide audience. The printing and illustrations are good.

Eye, Ear, Nose, and Throat. A Manual for Students and Practitioners. By WILLIAM LINCOLN BALLENGER, M. D., Assistant Professor of Otology, Rhinology, and Laryngology in the College of Medicine of the University of Illinois (College of Physicians and Surgeons); Professor of Otology, Rhinology, and Laryngology in the Chicago Eye, Ear, Nose and Throat (post-graduate) College, etc., etc., and R. G. WIPPERN, M. D., Professor of Ophthalmology and Otology, Chicago Eye, Ear, Nose, and Throat College. Series edited by BERN B. GALLAUDET, M. D., Demonstrator of Anatomy and Instructor in Surgery, College of Physicians and Surgeons, Columbia University, New York; Visiting Surgeon, Bellevue Hospital, New York. Illustrated with 150 Engravings and 6 Colored Plates. Philadelphia and New York: Lea Brothers & Company, 1900.

THIS manual belongs to the series of pocket textbooks issued by this well-known firm of publishers. It is fully illustrated and its mechanical work is beyond criticism. The authors have done their part of the work well and have wisely confined themselves to concise presentations of the various topics, avoiding all mooted points and the various discussions which fill up so much space in many books. While these are of interest to specialists and find an appropriate place in large treatises, they are not of utility in such a manual as the one here noticed. The book will serve as a valuable introduction to more pretentious ones.

Hygiene der Prostitution und venerischen Krankheiten. Bearbeitet von Dr. A. BLASCHKO. Mit 1 Kartenskizze und 2 Kurven im Text. Handbuch der Hygiene herausgegeben von Dr. THEODOR WEYL. Zehnter Band. Erste Lieferung. Jena: Gustav Fischer, 1900.

THE author of this monograph was one of those who attracted great attention at the Brussels conference last year by his unalterable opposition to the legalized regulation of prostitution and by the tenable position he assumed. The present work may be considered as a review of his attitude on the subject. He discusses in fullest detail the failure of regulation to regulate, giving as reasons the instigation by the legal measures to concealment of venereal disease, to the propagation of secret prostitution, to the inadequacy of examinations, and to the failure of physicians to report cases coming under their notice. The author gives a sketchy history of prostitution, discusses the distribution of gonorrhœa and syphilis, and, in his philosophy, regards prostitution as a necessity and a safeguard to the community. The work contains, also, directions for the treatment of the two principal venereal diseases and gives methods of preventing the spread of these ailments.

Although the author offers no remedy looking to the restriction of prostitution, the work must be regarded as an authoritative statement from one who has thoroughly canvassed the subject. To the resident of New York it should be especially interesting at this time.

BOOKS, ETC., RECEIVED.

A Manual of Practical Hygiene for Students, Physicians, and Medical Officers. By Charles Harrington,

M. D., Assistant Professor of Hygiene in the Medical School of Harvard University. Illustrated with Twelve Plates and One Hundred and Five Engravings. Pp. vi-17 to 729. Philadelphia and New York: Lea Brothers & Company, 1901.

A Treatise on Appendicitis. By George Ryerson Fowler, M. D., Professor of Surgery in the New York Polyclinic, etc. Second Edition, Revised and Enlarged. Pp. 7 to 235. Philadelphia and London: J. B. Lippincott Company, 1901. [Price, \$2.50.]

The Technique of Surgical Gynæcology. Devoted exclusively to a Description of the Technique of Gynæcological Operations. By Augustin H. Goelet, M. D., Professor of Gynæcology in the New York School of Clinical Medicine, etc. Pp. 7 to 340. New York: International Journal of Surgery Company, 1901.

Hypnotism and Suggestion in Therapeutics, Education, and Reform. By R. Osgood Mason, A. M., M. D., Fellow of the New York Academy of Medicine, etc. Pp. vii-344. New York: Henry Holt & Company, 1901.

Hypnotism. A Complete System of Method, Application, and Use, prepared for the Self-instruction of the Medical Profession. By L. W. De Laurence, Instructor at the School of Hypnotism and Suggestive Therapeutics, Pittsburgh. Illustrated. Pp. 5 to 256. Chicago: The Henneberry Company, 1901. [Price, \$1.50.]

Retinoscopy (or Shadow Test) in the Determination of Refraction at One Meter Distance, with the Plane Mirror. By James Thorington, A. M., M. D., Professor of Diseases of the Eye, Philadelphia Polyclinic, etc. Fourth Edition, Revised and Enlarged. Fifty-one Illustrations, Twelve of which are Colored. Pp. xviii-19 to 89. Philadelphia: P. Blakiston's Son & Company, 1901. [Price, \$1.]

Miscellany.

Osteopathy and Medical Gymnastics and Massage.—The following argument was prepared by Dr. H. V. Barclay, of New York, to be presented at a hearing on the Seymour bill in Albany on February 27th:

"I have the honor to appear before you as a representative of the New York Medical Gymnastic and Massage Society, a society incorporated under the laws of this State May 8, 1898, and founded for the advancement of medical gymnastics and massage, its membership being open to physicians and to those who hold no medical diploma.

"Having acquainted ourselves with the history, practice, methods, and claims of osteopathy and its institutions, of learning, our society has decided to send representatives here to protest most strongly against the passage of the present bill, intended to give them rights and privileges. Our reasons for so doing are: 1. That osteopathy, in spite of its claims to the contrary, is not a new school, nor a complete school, of medical practice; they are therefore not in position, as they confess themselves in their alleged text-books, to treat all forms of disease. Osteopathy, in principle, is nothing else or more than a certain form of massage and gymnastics, which, as we know, is a mechanical treatment, known from the earliest days of history, and which is based on scientific principles and the results of experience and modern research, and now recognized and employed by the medical profession all over the civilized world. But

osteopathy is not even a complete system of medical gymnastics and massage, since its operations embrace only a few manipulations, chiefly pressures applied to nerves and bones, and certain movements intended for passive stretching of contracted muscles and fasciæ. In reading their text-books I have not found a single thing of value but what has been known in the past.

2. We oppose the passage of this bill because osteopathy, as you have already heard mentioned in the remarks of physicians representing the Medical Society of the County of New York, claims to cure and benefit a large number of diseases which, on account of their causes and pathology, are entirely unsuitable for such treatment; nay, it is harmful and dangerous to patients suffering therefrom, and numerous instances have come to the knowledge of the members of our society in which positive harm has been done. The osteopathic practice is, therefore, a menace to public health.

"As a matter of fact, any impartial person who will take pains to investigate the practices and claims of osteopathy will find that the system rests largely on false claims and pretenses, which, if not wilfully held forth, can only be due to ignorance. And that this is so is not surprising, when we learn that instruction in osteopathy can be had at this day, as it could be and has been had in the past, in courses lasting from two to six months, personal attendance often not being necessary; and many are those who hold diplomas from this kind of schools. And these are the people who shall be allowed to practise legally and independently according to this bill. But even if those who in future may desire to obtain a license to practise osteopathy must qualify as provided by this bill, they will, nevertheless, be entirely unfit to be allowed such privilege, for the reason, as before stated, that their practice reduces itself to a very small part of regular medical practice, and as operated and practised by them is very often either entirely wrong or open to serious objections and doubts, which has been sufficiently demonstrated by other speakers.

"Masseurs and gymnasts who are not physicians will always be necessary and will be welcomed and supported by the regular medical profession, since, on account of the nature of their work, no physician, with the exception of those who have specially devoted themselves to this practice, will have the time, physical strength, technical dexterity, and skill requisite. But, while osteopaths are opposed to the regular medical profession and desire to apply their treatment exclusive of other treatment, the regular masseur and gymnast sees in his line of work only a part of regular therapeutic measures, and, although his is very often the only treatment required, he is not opposed to other beneficent treatment by the physician. Indeed, he is glad to have the physician at his side and have him point out the diagnosis, and is always grateful for information that will assist him to carry the treatment to a successful issue; in other words, he desires to cooperate with and work in harmony with the medical profession, who need him as much as he needs them. This is as it should be. The best men of our craft are already recognized and respected by the medical profession, upon whom they depend for their work, and had the medical profession at large recognized us in the past as they appear to do now, I dare say that osteopaths, common rubbers, and charlatans of various descriptions would never have had a chance to gain entrance into this State."

Twisting of the Pedicle in Hydrosalpinx.—M. Cathelin (*Revue de chirurgie*, February), as the result

of a detailed clinical study, formulates the following proposition: Every tense subumbilical tumor, fluctuating, dull on percussion, and mobile, with previous painful paroxysms and ending in an outburst of severe pain, extremely intense in the lower part of the abdomen, with vomiting, constipation, and without fever, should call to mind a hydrosalpinx with twisted pedicle.

Modern Gunshot Wounds.—Dr. E. F. Robinson (*Annals of Surgery*, February) thus sums up his conclusions in an article on Gunshot Wounds in the Philippino-American war: 1. The modern gunshot wound is generally aseptic, and should be treated on this supposition. 2. Asepsis is due chiefly to the character of the bullet, and the early application of first-aid dressing; and, in a minor degree, to the velocity of the projectile. 3. Primary hæmorrhage from modern gunshot wounds is exceedingly rare, the blood-vessels being displaced rather than cut by the rapidly moving projectile. 4. The "explosive effect" of the modern bullet is much less common than recent military literature would indicate. This peculiar destructive effect is produced by the character of the tissue struck, as well as by the great velocity of the bullet. 5. Gunshot wounds of chest are rarely infected. Simple antiseptic treatment, with aspiration of pleura in cases of severe hæmorrhage, is all that is necessary. 6. Gunshot wounds of knee-joint are usually aseptic, but, if infected, demand immediate amputation to save life. 7. Excision of elbow is always a justifiable operation in severe shattering or infection of that joint. Resection of bones of other joints is rarely necessary, erosion or amputation being preferable. 8. Injuries of nerves from gunshot wounds can often be benefited by operative interference or resection. 9. In modern military surgery, abdominal section for gunshot wound is not justifiable; the patient's best chance of recovery lies in conservative treatment without operation.

The State of the Liver in Erysipelas.—M. Roger and M. Garnier (*Revue de médecine*, February) consider that an important difference can be established between the streptococcic liver and the other varieties of liver infections. In streptococcic infections, the liver is only relatively attacked; it influences the course of the infection even more than it is influenced by it. The lesions that present prior to the cells being attacked aggravate considerably the prognosis of erysipelas. However, it is important to establish a distinction between erysipelas and the other streptococcus infections. Fatty degeneration is more frequent and more marked in the subjects of erysipelas; but it is probable that it was preexistent in a number of cases and that it only explains the mechanism of death by exposing to us hepatic insufficiency. A difference, on the other hand, must be made between the streptococcus infections of adults and erysipelas of young children; in the latter, the changes, save in one case, are but slightly marked, their cells seeming to resist the streptococcic toxins better than those of adults. In short, whatever form they assume, the streptococcic infections, even when prolonged, provoke diffused more frequently than very profound lesions; the changes are uniformly disseminated throughout the lobule. The erysipelatous liver is thus distinguishable from the divers anatomical types that we have described in studying the scarlatinal liver.

The Treatment of Chlorosis.—Dr. Seymour Taylor (*Clinical Journal*, January 2d), in a clinical lecture, de-

livered at the West London Hospital, says that the conclusions which he has arrived at in the treatment of chlorosis may be briefly summarized as follows: First, the carbonate of iron is the most efficacious remedy. Second, whatever preparation of iron may be prescribed, it must be fresh and free from oxidation. Third, until the intestinal canal is clear and the digestive functions are in good order, no preparation is of much or any avail. But this is not all. Chlorosis refuses to come within such a simple limitation as this implies, and consequently we meet with cases in which all these precautions have been taken and yet failure results from our treatment. The reason, he finds, is that there is more than one type of chlorosis. There is the type in which dyspepsia and stomach symptoms are the most pronounced, and these are more pronounced still as the pallor increases. Secondly, there is the neurotic type, in which hysteria and other nervous manifestations are so common. This patient is often thin and ill-nourished. There is yet a third type in which pallor and breathlessness are the marked features. These patients are for the most part plump, well-nourished young women. All these varieties show, sooner or later, if left to themselves, symptoms which, to say the least, are highly suggestive of gastric ulcer. In the dyspeptic class he invariably treats the dyspepsia first. It may be that it requires a week or month or even longer before we restore the proper functions of the stomach, but until this happy period arrives he is averse to the exhibition of any ferruginous remedy. He has records of a good many failures mentioned in this line of practice. Therefore he gives a simple stomachic mixture containing bicarbonate of sodium, hydrocyanic acid, and gentian, to which may be added cascara, euonymin, or other purgative, if necessary. At the same time the patient is rigidly dieted. The patient of the neurotic type is often more difficult to relieve. The want of nutrition may be attributed in part to dyspepsia, which is also present, and in part to the disinclination to take food, which is a frequent symptom; this condition borders on the anorexia nervosa which Gull described. Here valerian is of great use, and the ammoniated tincture may be added to the prescription. Afterward, when food is being assimilated, we may add cod-liver oil after meals, and possibly also iron, such as steel wine, which we often give to delicate children. The third type may begin to take iron earlier than the others, and arsenic may be given in addition. Some physicians contend that arsenic is the saving remedy, and that, when iron fails to relieve, it can be supplemented or supplanted by arsenic. Whether this is so or not, arsenate of iron beginning with $\frac{1}{36}$ th of a grain three times a day is a valuable remedy.

But, whatever preparation of iron is selected, the careful estimation of the percentage of hæmoglobin in the blood is strenuously insisted on. This estimation should be made at least once a week, and the preparation changed from time to time if no progress be made.

In other words, the measure of the utility of a prescription will be given by the hæmoglobinometer. If the weekly examination of the blood shows a steady—it may not be a great—increase in the amount of hæmoglobin, then that prescription may be continued. But if, on the other hand, the amount of hæmoglobin stands still, or is even diminished, another preparation of iron must be found. Dr. Taylor finds that the percentage of hæmoglobin after careful administration of a proper and suitable preparation of iron, varies from 1 per cent. to 3 per cent., the average being 2.11 per cent. This computation is taken from forty-three cases in his out-patient work.

THE NEW YORK MEDICAL JOURNAL, APRIL 13, 1901.

Original Communications.

GERMAN TEXT-BOOKS HALF A CENTURY AGO; HISTORY AND REMINISCENCES.*

By A. JACOBI, M. D.,

NEW YORK.

IN the year 1847, when I commenced the study of medicine, it was not what it is to-day; least of all was it cosmopolitan, it was thoroughly national. There was an English medicine, there was a French medicine, and there was a German medicine. The sober and practical turn of the Anglo-Saxon mind was never drawn away from its direct methods of clinical observation and teaching. Not even John Hunter's categorical dictum, "Do not think, try"—that means experiment—was an exception to this general rule; and no theoretical teaching like that of Brownianism, though British in its origin, ever controlled English thinking as it did that of the continent.

In France, while the greatest man in its political life was spreading all over Europe the results of the great revolution through violence and murder, a young scientist revolutionized medical science by his genius and hard work. That is what Bichat did when he studied the physiology and histology of the organic tissues. After him, there are three names that will immortalize France, though her political existence may have disappeared from the records of the world. Laennec, preceded only by Auerbrugger and Corvisart, who had long been forgotten, remodeled diagnosis by percussion and auscultation. Magendie created experimental physiology and pharmacology by introducing alkaloids, such as quinine, morphine, veratrine, strychnine, piperine, and emetine, and bromine and iodine into practical therapeutics. Broussais overthrew ontology—though he proclaimed one of his own—localized disease, urged preventive and abortive treatment, studied the anatomical lesions of morbid processes, substituted the method of anatomical thinking for the merely clinical and empirical observation of the sick, and thus was the intellectual author of that reasoning and knowledge which later were known under the name of the Vienna school. Indeed, not only did Broussais transmit to the latter his anatomical way of thinking, but, unfortunately, he also taught them to be satisfied with the observation of coarse anatomical lesions and with the name of a diagnosis, adding the assurance that those lesions must terminate fatally; that, indeed, every case of sickness would either get well spontaneously or was absolutely hopeless, and that treatment was powerless.

These famous men, surrounded or followed by dozens

*Read at a reception given by Dr. Jacobi to his friends, in the New York Academy of Medicine, on Friday evening, April 5, 1901, in commemoration of the fiftieth anniversary of his graduation in medicine.

of other great minds, gave France its superiority during the first half of the century down to the time when I began my studies. Meantime, Germany—poor and forlorn, divided into hundreds of political shreds, large and small, tyrannized and robbed by her dukes and bishops and princelings of every calibre, annihilated by Napoleon, whom she finally expelled through the unbounded enthusiasm of what was considered a holy war—Germany evolved a peculiar romantic fanaticism which controlled her literature for a decade, with unfavorable results on science. Then came decennia of brutal political reaction and cruel suppression of every ideal effort, police and military violence, and the dungeons filled up with the flower of the country. Schiller long before had extolled "freedom, though in chains"; chains, indeed, were plentiful, and that sort of freedom made Germans transcendentalists. Their method of studying Nature was imagination. Even Kant, the mathematical thinker, taught them to construe things *a priori*. Then came Schelling.

According to Schelling, "the greatest problem of the science of Nature is the development of the first law, from which all the rest of the laws of Nature may be deduced," or, in other words, it is the greatest problem "to find Nature in its greatest simplicity." Such a law, whose existence he simply postulates, must (so he says) "have a more sublime foundation than that of sensual experience; that foundation can be attained only by speculation on the basis of transcendental philosophy." It need not be said that a system built on this poetical and metaphysical theory could not but have, when applied, the saddest influence on medicine and the study of Nature in general.

The books of several decades of that period are absolutely obscure, abstruse, unintelligible, and verbose. That they ever taught anybody is impossible; it is impossible to-day to translate them into any—even the German—language. Inflammation, for instance, in the words of the elder Marcus, was the condition in which the "electrical essence is affected in the dimensions."

The whole literature was full of such nonsense, and full of contempt for the unphilosophical, practical foreigners, for Bright and Laennec.

There was, however, a professor of theology, Paulus, in Heidelberg, who, in spite of living in metaphysical occupations and accustomed to accept traditions, saw these errors of medicine distinctly. He saw danger to medicine in Schelling's philosophy, called its influence "tragic" and "pickpocketism," warned against speculative theories invented in the study room, and attributed the low status of German medicine, when compared with the French, to faulty methods.

Hill, Schoenlein, the clinician, and Liebig, the chemist, having prepared the medical minds, the Vienna school, Rokitansky, Skoda, Hebra, and many others roused immense enthusiasm. Broussais's French doctrines, good and bad, were readily accepted. Only his

ontological gastro-enteritis, the *fons et origo* of every ill, was replaced by Rokitansky's doctrine of the crases of the blood, which after a very few years was unmercifully slaughtered by Rudolf Virchow.

In Rokitansky's opinion, there was nothing in medicine worth knowing except the anatomical lesions. Skoda's ill success in his careless experimentation with remedies also contributed to the confirmation of Broussais's nihilism, in spite of the vigorous protests of Laennec.

At that time, Dietl (1804-1878), professor in Cracow, expressed himself (1851) as follows: "The ampleness of our knowledge is not proportionate to the results of our practical labors. Our ancestors cared much for the success of their treatment; we, for the result of our investigations. Our tendency is purely scientific. The physician must be judged according to the amount of his knowledge, and not according to the result of his cures; it is the investigator, but not the healer, that is to be appreciated in the physician. As long as medicine is art, it will not be science. As long as there are successful physicians, so long are there no scientific physicians. Our power is in knowledge, not in deeds."

These articles of a narrow-minded creed met with the strong approval of Joseph Hammersik, who had been professor in Prague since 1849, and was removed in 1853 on account of the grossness of his nihilism, which was recognized, together with other irregularities, as a positive danger to the sick in the hospitals.

As a result of their teachings, what had been observed in France during the prevalence of crude anatomism was repeated in the German-speaking countries, viz., this therapeutic nihilism found its adherents among the young and utterly inexperienced. History always repeats itself. To-day we are just emerging from a period in which a subordinate branch of ætiological research, of the greatest import, it is true—I speak of bacteriology—like a young Napoleon, threatened to fill the whole field of medical science and art, and so disordered the monomaniac minds of the young that they saw no medicine, past, present, or future, except in the northern exposure of the laboratory windows or in the bottle wilderness of the dingy laboratory of their own school, in their own city, of their own country.

The learned and older and wise men, such as Helm (1875), of Pavia and Vienna; Hebra (1880), of Vienna, and Duchek (1882), of Vienna, while readily accepting and practising both anatomical and diagnostic teachings, reestablished the belief in the responsibility and the results of the practitioner.

Oppolzer's name should never be forgotten among the great and wise benefactors of medical practice (1871); he taught in Prague, Leipsic, and Vienna, and as early as 1848 thus expressed himself in his inaugural address at Leipsic: "Those are greatly mistaken who believe that a modern physician is he who examines a

patient most carefully, auscultates and percusses, and is satisfied when the autopsy corresponds with his diagnosis. Such a medical man does not comprehend that the most sublime aim of all medical service is the healing of the sick."

In connection with Oppolzer, the name of Wunderlich, of Leipsic, should not be forgotten. He was one of the first, perhaps *the* first, outside of Austria, to appreciate the labors of Rokitansky, Skoda, and Kolletschka. In a little book on French medicine and the young school of Vienna, he proved not only the presence of many new facts in their writings, but of absolutely new points of view.

That was the time in which the physicians of Germany, ignorant, nebulous, unacquainted with all that had been done in France, and with the fact that the Vienna school was only the continuation and evolution of Laennec, looked upon Vienna as the new Mecca and on its teachings as absolutely new discoveries. About that very time a number of old journals died of inanition, and new ones took their place.

Never was there among the teachable minds such a sudden intellectual revolution. After a very few years the first volume of Virchow's *Archiv* made its appearance. What it means for the history of medicine in the second half of the nineteenth century, and for all time to come, you all know. No matter how many errors have been committed since, from that time on there are no "schools" in scientific medicine. It became clear to all that there could not be parties in medicine any more than in physics, chemistry, astronomy, or mathematics, and that intriguing, blind, or eccentric persons might be able to blind the ignorant, semi-instructed, or credulous public, but not to influence the quiet, systematic biological methods of hard-working investigators.

In that time, from 1847, I had the good fortune to begin the study of medicine, in which I am still engaged. Modern medicine was born about the middle of the century; it has been young since, and will always remain so, for its methods are biological, those of the study of Nature such as she is. It has freed itself of every sort of transcendentalism. It can afford to do without metaphysics and creed, and is, therefore, as tolerant as it is becoming more profound and more independent.

Not long before Stieglitz, an old and widely learned practitioner, had expressed himself in 1840 in the following terms: "German medicine has sunk so low and is so emasculated as to make any shaking up desirable. Whatever gives it a new direction will be wholesome, though new errors or perversities may result therefrom."

But recovery from the turbid ocean of what was called "nature philosophy" was close at hand. In 1842 two new journals appeared, viz., Roser and Wunderlich's *Archives of Physiological Medicine*, and Henle and Pfenger's *Magazine for Rational Medicine*. Both of these gathered around their flags not only many of the young and unprejudiced, but also the numerous middle-aged

or older men who had followed the new paths hewn in the thicket of German nebulosity by the anatomical and diagnostic results of Parisian and Viennese industry and genius. It was the time of a general upheaval in science, religion, and politics. Oppolzer's address was delivered in 1848, the very year of the German revolution. I still see an older friend in Greifswald, who, from the table on which he had posted himself, waved the newly-arrived pamphlet and exclaimed: "Here is another revolution, a real declaration of independence!"

Among the number of the older men of the reformers was Krukenberg, in Halle (who died in 1865), a clear, skeptical, and consistent man, the upholder of the unity of medicine. August Hirsch says of him, quoting a biography, that the separation of medicine and surgery appeared to him unnatural and repulsive, and he threw all the powers of his sarcasm over those who profited by the hypocritical claim of jealous superiority. You need not believe, however, that, to judge from general appearances, he meant to castigate the surgeon. At those distant times, when surgery had not yet profited by the later results of laboratory and experimental chemical and physiological research, he alluded to the clinician and not the surgeon.

Two other men were Romberg (1843), in Berlin, whose text-book on diseases of the nervous system appeared from 1840 to 1846, and whom I saw but once when I was a young man, and my own dear old teacher, Friedrich Nasse (1851), in Bonn. He was as learned as he was humane; theoretical and practical, pious and critical, a follower of Messmer and of Laennec, experimenter and teacher, and, as I experienced in my own person, first a good hater and then a loving protector.

He was born in 1778, and died a few weeks after he graduated, on April 4, 1851, Carl Otto Weber, the great investigator and surgeon of Heidelberg, who died in 1867 of diphtheria contracted by sucking out the wound of a tracheotomized child—the patient recovered, the physician died—and me. Nasse was a disciple of Reil, a moderate follower of Schelling's philosophy, at those times a good physiologist, pathological anatomist, and a thorough clinical teacher, and, at the same time, a believer in animal magnetism to such an extent as to try to make his hearers enthusiastic over it. Once he wished me to go to Holland to magnetize a young hysterical lady, which office I declined. On the other hand, he made me inject the subcutaneous tissue of rabbits with putrid material, to study its effect.

His writings were many, from those on animal magnetism (together with Ennemoser, who explained the relations of Adam to Eve by that alleged force, and taught how to magnetize the trees in the field and the child within the mother) to experiments on the elimination connected with the respiratory changes of the blood (Meckel's *Archiv*, 1816), regeneration of nerve tissue (Müller's *Archiv*, 1839), combustion and respiration

(1846), and a large number of essays on physiological and psychiatric subjects. He was the strongest adherent of Laennec, and never tired of drilling us for hours daily, for the eighteen months I worked under him, in auscultation and percussion and chemistry, in spite of the element of mysticism in the great man's nature. Indeed, the facilities for clinical instruction in my university were far superior to those of most German universities, not to speak of our own medical schools in this year, 1901. Almost all of the second half of the third year of study, and all of the fourth year, were filled exclusively with clinical and operative work; from morning to night we were engaged in the medical, surgical, or obstetrical hospital wards, in the operative courses, or in practice among the poor of the town, who were attended by the clinic. We had to report on every case, and our histories and our prescriptions were scrutinized, the latter not only for their appropriateness, but also for their expressiveness. Every prescription for which the apothecary charged more than "drei Silbergroschen," about seven cents, was closely criticised. You see, our young men at present are less favored. It seems we shall have to wait a long time before every medical school will have its own hospital for the constant employment of eager students.* During the years in which I studied medicine, from 1847 to 1851, viz., three semesters in Greifswald, two in Göttingen, and three in Bonn, some of the principal discoveries or applications of old ones were made. Some should be mentioned. In 1847 ether anæsthesia was used in obstetrics by Hammer, in dentistry by Delabarre; prismatic glasses were employed by Kreke and Donders; chloroform was introduced into obstetrics by Simpson; the scapula was extirpated by Fergusson; faradization was recommended by Duchenne; unstriped muscle fibres were described by Kölliker; Semmelweiss discovered in the autopsy of Professor Kolletschka, who died of sepsis, the same lesions that are found in puerperal fever. In 1848, Crusell, of Finland, explained the indications of galvanocaustics; the quantitative analysis of urea was taught by Bunsen; and Malmsten discovered the *Trichophyton tonsurans*. In 1849 Arnott taught local anæsthesia by cold; Bernard performed the "piqûre" of the fourth ventricle and caused diabetes; Pollender found bacilli in animals infected with anthrax; Hutchinson invented the spirometer; and Meigs found thrombosis to be a cause of death in puerperal women. In 1850 another American, William Detmold, of New York, opened an abscess in the brain and was roundly abused as an American swindler, even in the sixth volume of Virchow's *Archiv*; the velocity of nerve irritation was measured by Helmholtz; the finger was described by Notta; and I. Walker proved the infectious character of secondary syphilis. In 1851 Helmholtz invented the ophthalmoscope and studied the duration and course of the induced current. Virchow

*In many other respects that period of which I speak is quite remarkable.

discovered the sheath of the cerebral vessels; Bernard explained the vasomotor function of the sympathetic nerve; and Romberg published his studies on *tabes dorsalis*.

An interesting fact connected with the history of the grand and lovely man is the fact that he advised (*Hufeland's Journal*, 1811) the use of the thermometer in scarlatina as a result of the observations made in Bielefeld, 1809, where he practised medicine before being called to the professorship of clinical medicine in the newly established university of Bonn, in 1818.

What there was of experimental general pathology at those times had been established by John Hunter. But there was no ætiological basis for the theory or practice of medicine. Until the middle of the century the majority of diagnoses were symptomatic. Cyanosis, fever, icterus, diarrhœa, apoplexy, dropsy, paralysis were considered full-fledged and scientific diagnoses. Not long before my time Puchelt said that *gastricismus* changed into a gastric fever, and gastric fever into typhus.

All this old Nasse would not allow. Both his teaching and his friendly sarcasm made us look for causes, for an anatomical diagnosis and for proper indications.

Altogether, this mixture of many sound, and oft-times unsound, theories and tendencies was usual in those early times of his, when hardly any German university was free from the influence of Schelling's philosophy.

Among my teachers thus influenced to a certain extent was Moritz Ernst Naumann (1861), who wrote a general pathology, in six big volumes, but did not expect us to know all of them—for he was a kind, humane, and genial man; also August Franz Joseph Mayer, an anatomist; Weber, the anatomist, who, after having learned that I, though a poor boy, was the possessor of his anatomical atlas with life-size pictures, forgave me for having studied anatomy and dissected in other universities.

Christian Heinrich Bischoff was the professor of *materia medica*. One March morning, in 1851, my friend Weber and I paid the prescribed calls previous to the approaching oral examinations, Weber in his own, I in a borrowed swallow-tail and silk hat. You permit this, and other reminiscences. *Senectus loquor*—and you told me last year I was seventy.

Weber was Bischoff's nephew, so he addressed him with "uncle." "I am not uncle, I am for you these months *der Herr Geheimrath*. Your ignorance is not relieved by the honor of your relationship to me." And to me he said: "My dear sir, what shall I say to you who have insulted me, the honored man of science, in my own lecture-room, and told me in the presence of a hundred hearers you would never come again, and marched out? Don't you see that you cannot help being absolutely ignorant, even more so than this other young man?"

Nothing was left to us but to beat a hasty retreat and

to learn his unintelligible, preposterous text-book by heart. So we did. This is my diploma.

Harless was the professor of the history of medicine. He told us both that we had never attended his lectures; he excused me on account of not having been in Bonn more than three semesters, but Weber had no such plea, having had all his eight semesters there. He assured us solemnly that he had been the prop of science, "*die Stütze der Wissenschaft*," for fifty years; and he did not see much help for us; but still, you see, this is my diploma.

Our surgeon was Karl Wilhelm Wützer, whose memory should ever be green. He was a splendid anatomist and a skilful operator. After Jobert de Lamballe, he was the most patient and, therefore, in spite of clumsy instruments, successful operator for vesicovaginal fistulæ. His great experience made him believe in the ubiquity and omnipotence of syphilis, therein preceding Fournier and Erb. I still see him scrutinizing us with his piercing but good-natured little eyes, and quietly suggesting, "Everybody is a little syphilitic."

He wrote very little. The time when every teacher, would-be teacher, and looking-forward-to-the-near-time-of-being teacher, had to write a text-book, had not yet arrived. Our text-book on surgery was, therefore, *Chelius*, without any title but *Chelius*. My edition, the one before you, is of the year 1846. I believe, before it disappeared and gave way to Billroth's and to Bardeleben's books, there were two dozen editions. I had another teacher of surgery before him who hardly ever wrote a line and who won the fond admiration of all. That was Baum, in Göttingen. He was the director of a country hospital in the far East when he was called to the professorship of surgery in the University of Greifswald.

When Dieffenbach died in Berlin, in 1847, Baum was proposed with Bardeleben as his successor. In the same year he left Greifswald for Göttingen; there I followed him to enjoy his teaching and that of Frerichs, who at that time, with Virchow in Würzburg and Rokitsansky in Vienna, was the only man who taught in Germany pathological anatomy and histology. Baum was a good, practical teacher, a fine operator, a lovely, sweet character, and learned beyond what we thought to be the legitimate right or destiny of any single man. All his immense library went into the possession of an American, Nicholas Senn; I think it forms part of the vast donation in books that that singularly gifted and active man has presented to the Rush Medical College. Thus is the distance between two hemispheres and two half centuries bridged over. Never think or say that the doings or the sayings of an individual man must needs amount to nothing. History, it is true, makes men; but there are men that contribute to making history.

Let me add a few more words on hill-clad, jovial Göttingen. There I enjoyed the lectures and the laboratory exercises of Woehler and of Wiggers, who was only

laboratory professor, and the assistant of the immortal chief, Wachler. Wachler contributed a great deal to the recognition of the unity of the universe by teaching the identity of inorganic and organic matter. It was he who synthetically constructed urea and laid the foundation of organic chemistry. Perhaps you will appreciate the enthusiasm the quiet, quaint little man could rouse in his students on taking a look at these text-books of his; it was the greater, the more I had suffered in Greifswald, in 1847, from the fossil that taught what he thought was zoology and natural history. He wanted us to swallow the doctrine that nitrogen and carbon were only compounds of hydrogen and oxygen, and even hydrogen was not simple. His teaching was quite congruous with what he introduced as an incontrovertible example; he did not see why all the elements could not be derived from one element, as all mankind, white, black, green, and red, came from the one Adam.

Conrad Heinrich Fuchs, who died in 1855, was my clinical professor in Göttingen. He published several essays on historical and pathological subjects, a text-book on the morbid changes of the skin (1840), and one, in two volumes, on *Surgical Nosology and Therapeutics* (1844-1846). It follows the Schönleinian system, is very learned, and contains much that is original, but suffers from the exaggerated application and display of his philosophical learning in this, that he coined any number of jaw-breaking technical terms. But his scientific conscience was sound.

At the meeting of 1841 of the Association of German Naturalists and Physicians, during the discussion of a paper read by Haeser on the parasitic nature of diseases, he expounded what he and others meant when they called themselves the "naturhistorische Schule"—natural-historical school of medicine. It was not to be taken as an exclusive theory, but the name indicated only the tendency of modern medicine to introduce and follow the same methods that were employed in the rest of the natural sciences.

I may here also mention the other clinician of Göttingen, Professor Conradi. His best and really good part was his first assistant, Dr. Schraeder; he percussed and auscultated with us and made the diagnoses for his superior officer, who was strong in ætiology. Conradi would never rest until the patient, worried and weary by his persistent cross-examinations, would reluctantly admit that some time before falling sick he had drunk something cold. Triumphantly the little, old, wrinkled man would turn to us, smile knowingly, and whisper: "Ja, ja, ein kalter trunk."

In Göttingen I also attended the lectures and demonstrations of Conrad Langenbeck, the father of Max and the uncle of the famous Bernard Langenbeck. Langenbeck was, in my time, until Baum came and took surgery—listen, if you please—professor of anatomy and of surgery and of ophthalmology. That was the period in which the bacilli and the cocci had the best of it. He

taught and worked before the era of anæsthesia, when accuracy and lightning speed were the characteristics of the operator. The story was told of an amputation of the thigh of his, which was performed in the presence of an eminent British guest. When Langenbeck took the knife, the Englishman opened his spectacle-case; when he had adjusted his glasses, the limb was off.

The most brilliant of my Göttingen teachers was Hermann Lotze (1817-1881), philosopher and naturalist. As early as 1842 he wrote his *General Pathology and Therapeutics as the Science of Natural Mechanics* (*Allgemeine Pathologie und Therapie als mechanische Naturwissenschaften*). He was one of the few I have met in my life that gave the lie to the observation that the most eloquent men were seldom successful teachers.

Rudolf Wagner was our physiologist and embryologist (1805-1865). In 1835 he discovered the germinal macula in the human ovum, and in 1853, together with Meissner, the tactile bodies. In his discussions with Carl Vogt, the German-Swiss zoologist, anthropologist, and revolutionist, in which he displayed his biblical piety, he was sadly worsted, but his fame will last on account of his actual services. The greatest of them is, perhaps, the *Handwörterbuch der Physiologie*, in these four volumes, to which Frerichs and many others contributed their classical labors.

Let us return to Bonn. Our obstetrician was Hermann Friedrich Kilian, who died in 1863. He was a good Lutheran in this, that he loved wine, woman, and song: "*Wer nicht liebt Weiber, Wein und Sang, der bleibt ein Narr sein Leben lang.*" He was a jovial storyteller, mostly on obstetrical lines. They all began with the words "In a cold, dreary, stormy November night." When he began to look solemn, we would all hum "In a cold, dreary, stormy November night," and never were mistaken. He was rather human. He thought so much of himself that he could not endure the good repute of others, even of students. When he was told that two candidates for the honor of the doctorate were excellent men and would pass a brilliant examination, he felt he must be of a different opinion and show their worthlessness. So, after the oral examination, he proclaimed that Weber and Jacobi were failures after all, and he had always known it. But the general wrath excited in university circles by that pronunciamento was too much even for him, and when he came to criticise our examination papers he gave vent to his overjoyed enthusiasm over their alleged excellence.

His text-book was learned and practical; its teachings were of the greatest service to me in the many hundreds of five- or ten-dollar cases I attended nearly half a century ago, in the tenement-houses of New York, not infrequently perched on a wooden stool all night in the company of the parturient woman and the bugs and roaches of her dwelling, waiting for the baby that I had to take, to wash, and to dress, for better, for worse.

Of other medical officers of the University of Bonn,

I should mention Dr. Schaefer, the first assistant of the surgical clinic, admired and beloved by all of us on account of his skill and the practical sympathy he showed us. The next was Dr. Louis Lehmann, the assistant to the obstetrical clinic. He died only last year, at what people call an advanced age, though he was only seventy-five, at the mineral spa of Oeynhausen, where he lived several dozens of years and published, besides a text-book on the spas of Europe, a number of scientific papers connected with that topic. The third and most illustrious of them was Dr. Hermann Weber, the first assistant of the medical clinic, now Sir Hermann Weber, of London, where he has lived since 1851. He is the eminent climatologist and consulting authority on subjects connected with mineral springs, climate, tuberculosis, etc. In Bonn he favored me and was interested in me, as he told me some time ago, because he found me different from the rest and rather queer. In the clinical town practice, of which I had a good deal, he was of great service to me. But lately we discussed the case of poor old "Abraham" of the "Judengasse," a man of seventy-eight years, who had double pneumonia. The treatment at that time consisted in many big doses of tartar emetic and of venesections, of which I made two on his foot. He had tartar emetic, two venesections, and me for a doctor, and, still, he got well. Doctors have their fate, like books; and sometimes it happens that their "work follows after them." Sometimes, however, they follow their work, as, for instance, that young doctor whom Kussmaul mentions in his charming *Reminiscences*. He relates: "The young doctor was stopped by two funerals. Anxious to get on, he inquires whose funerals they are. 'But, Herr Doctor,' says a bystander, 'they are the patients you saw yesterday.' 'Not possible!' says the doctor; 'I had three of them.'" The story does not say whether he did follow his work, but, sometimes indeed, our work follows after us. There was, for instance, in the pauper practice of Bonn, a family named O——, to which I was sent to treat a young child. It was in 1850. There were the retarded and irregular pulse, the vomiting, the occasional flush, the slow rolling of the eyes, and the ominous up-and-down movement of the upper lid of tuberculous meningitis. When I expressed my sorrow at the unavoidable termination, I was told that they had lost eleven children before, mostly of the same disease. The case was not closed with the autopsy, for when I had been in New York a few months, there called Mrs. O——, who had migrated while I preferred to be idle in Prussian state prisons, and was engaged in building up a respectable and successful business. She told me she thought highly of me because I recognized the illness of her last child, though I was only a "clinicist," and engaged me as her doctor. We were good friends for forty years, thinking much of each other—she of my medicine, I of her picture frames—until she died a few years ago.

I now introduce a few of my old books, such as I

have not mentioned before. Carl Friedrich Canstatt, who died in 1850, first a general practitioner and finally professor in Erlangen, whose great handbook, in four volumes, with a supplement, you see here, was never affected by metaphysical theories. This great work, which he commenced in 1841, like his *Diseases of Advanced Age* (1838) and previous ophthalmological papers, was founded on pathological anatomy and chemistry, physical diagnosis, and practical experience. It was, therefore, the bible of German medicine, until finally Niemeyer, with his lucidity, directness, and beauty of language, and, lastly, Strümpell, who exhibits the same wonderful qualities, took his place in the esteem of the medical public. It is a great work, and the wonder is that one man could furnish it, so learned, practical, crude, and of immense size. It compares favorably with the brilliant cyclopædias that every country has brought forth in the last decades.

My chemistry professor, Friedrich Ludwig Hünefeld, under whom I studied in Greifswald from 1847 to the autumn of 1848, published a *Chemistry of Jurisprudence* which was highly esteemed in my time; but this book here, by Heinrich Schürmayer, of Heidelberg, on *Forensic Medicine*, was superior to the few works that had appeared on the same subject since Johann Peter Frank (1821), Adolph Henke (1843), and Wildberg (1850) tried to establish the new doctrine on a sound, scientific basis.

Johannes Lenni's books on zoology and on botany were much used. The author was a Catholic priest. Lehmann's *Physiological Chemistry* was an epoch-making work, and is classical this very day. Eydam's *Electricity and Magnetism* contained everything known up to 1843. Von Gaal's, with an appendix by Neller, on physical diagnosis, was a superior work, with good plates.

One of the special text-books much used at that time was Werthmüller's *Augenheilkunde*. To me it was of special value and proved of more than local service—that is, however, what every specialistic work should be—for, strapped over my revolting abdomen, it protected me against seasickness when, in forty-three days, I crossed the Atlantic on the good Boston three-master *Trimountain*, Captain Rea, in September and October, 1853. That trip closed my European life, the last two years of which, after my graduation, had been an entire loss to me.

When, nearly a year ago, Osler praised me publicly for not having written anything for publication in the seven years following my graduation—not even this paper, which contains my experience in a cholera hospital with which I was entrusted after returning from a short dissipation in the Schleswig-Holstein war in 1850, has ever seen the light—he did not know that in nearly two years of those seven I never saw a square inch of paper or more than an infinitesimally small pencil which I concealed in my hair. When I saw the light again, the French Republic had been destroyed nearly two years

and the world had changed its shape. But medicine had meanwhile contrived to further evolve the new methods in which I was raised, and I found myself at home again under the folds of its flag inscribed with the gospel of biological research. Thus, I had something to live for. I rejoiced in the fact that medicine was no longer, would never again be, the victim of a single theory or the work of an individual man, but the results of ever so many thousands laboring in all countries and languages with the same methods for a common aim. That is what kindled the hope and enthusiasm of the forlorn young refugee who, in October, 1853, landed under the shadow of Bunker Hill, though there was nobody to receive him but the crisp autumn air of a free country, and though the shore was not covered with sick people that waited for his arrival or looked forward to his ministrations.

A SHIELDED PISTON SYRINGE FOR URETHRAL AND VESICAL IRRIGATION.

By J. RILUS EASTMAN, M. D.,

INDIANAPOLIS.

THE usefulness of permanganate of potassium irrigation in the treatment of gonorrhœal urethritis has been established beyond cavil. There remain, however, differences of opinion as to certain details of technics involved in the execution of these irrigations.

Since Janet, a few years ago, enunciated his now well-known precepts concerning the use of permanganate solution—hot, often copiously, and under pressure—considerable time and art have been devoted to the invention and perfection of apparatus for the accurate application of these principles. The result is a departure from the older methods of treatment in gonorrhœa, amounting to revolution.

Janet's original irrigation apparatus consisted of an ordinary rubber fountain syringe bag, to which was attached a rubber tube bearing a blunt or conical hard-rubber nozzle. The anterior urethra was irrigated by fitting the nozzle to the meatus and releasing a pinch-cock, and the posterior irrigation accomplished by distending the anterior urethra with the solution and elevating the syringe-bag or reservoir to a height sufficient to overcome the resistance of the cut-off muscle—seven or eight feet.

The apparatus devised by Valentine is somewhat more complicated. It consists of a glass percolator jar held in a sliding frame. The force of the irrigating stream is regulated by raising or lowering the jar. A piece of rubber tubing, six feet long, is attached to the funnel-shaped lower end of the percolator, and into the distal end of the tubing is introduced a blunt glass nozzle of any desired one of several forms. The tubing is provided with a notched trigger pinch-cock and with a glass finger-bowl-like protective shield, which is placed just back of the butt of the nozzle, serving to prevent

soiling of the operator's apparel by the permanganate solution as it spurts from the meatus. Valentine has more recently devised, for home use, an irrigator fashioned upon the general principles indicated above, but constructed almost entirely of soft rubber. His contrivances and writings have been largely instrumental in bringing the irrigation treatment into popular favor in America.

Chetwood, likewise, has devised an excellent appliance for urethral irrigation. This consists of a blunt nozzle with an afferent and an efferent tube, which permits moderate distention of the urethra and provides for the emptying of the urethra without withdrawal of the instrument. The shielded hard-rubber nozzle used by Lydston is simple, ingenious, and useful.

In all the appliances mentioned above, the fountain syringe principle is employed, the sliding frame, percolator, and peculiar nozzles representing modifications

FIG. 1.

only. They may, therefore, be considered together. They have in common several objectionable features:

First, They are not easily sterilizable.

Secondly, In any solution of potassium permanganate there may be present small crystals. These will gravitate to the bottom of the syringe-bag or percolator and will be first to enter the patient's urethra, perhaps causing distressing irritation. If the weaker irrigation solutions were always made from strong "stock solutions" this accident might be avoided, to be sure; but the strong solution is not always at hand.

Thirdly, In cases where it is not desired to force the cut-off muscle and irrigate the posterior canal, it is not easily possible to instantly shut off the current when the muscle is discovered to be relaxing.

Fourthly, It is difficult to accurately gauge the pressure.

Fifthly, It requires considerable time to fill the bag or percolator for each irrigation.

In view of these features, the writer has found it convenient, in irrigating according to Janet's teaching, to dispense with every complicated apparatus and to use a large metallic piston syringe armed with a rounded, blunt nozzle and provided with a movable protective shield. This instrument possesses the following advantages:

First, It is easily and entirely sterilizable.

Secondly, The solution is taken from the top of a column of liquid, as, for example, in a large graduate (see Fig. 1), and crystals that may be present in the bottom of the receptacle are not taken up.

Thirdly, With the piston syringe the pressure exerted may be finely gauged by the resistance against the operator's thumb pressing the piston.

Fourthly, The force of the current may instantaneously be lessened or the stream entirely cut off.

Fifthly, The use of the instrument is attended with no inconvenience or loss of time.

Sixthly, It is easily transportable.

Seventhly, It is simple in construction and application.

It consists of a five-ounce metallic piston syringe with detachable blunt nozzles. A thin-spun metal shield (see Fig. 2) surrounds the barrel. The shield is made movable, in order that it may be held up while the nozzle

FIG. 2.

is introduced into a graduate or other vessel for filling. The syringe being filled, the shield is pushed down along the barrel and fastened by a slot-and-pin catch about an inch behind the tip of the nozzle.

With this instrument the precepts of Janet and Valentine can be carried out to the letter—*i. e.*, the so-

lution of potassium permanganate can be introduced hot, often, copiously, and under pressure. It greatly simplifies the technics of irrigation. With the Valentine apparatus the procedure is made unnecessarily laborious, absolutely nothing being accomplished which cannot be done equally efficiently with the simpler shielded piston syringe. The latter has been made for me by W. H. Armstrong & Co., of Indianapolis.

THE CORRECTION OF THE DEVIATIONS OF THE NASAL SÆPTUM,

WITH

SPECIAL REFERENCE TO THE USE

OF THE

AUTHOR'S FENESTRATED COMMUNTING FORCEPS.*

BY JOHN O. ROE, M. D.,

ROCHESTER, N. Y.

THE importance of a normal nasal sæptum in the human economy is so uniformly recognized that various writers have been led to discuss the subject, and many operators have devised different methods for the correction of the numerous deformities to which the sæptum is subject.

Nearly every one of these methods is found to possess some merit and to have advantages over others in certain particular cases or conditions, but the method that has proved most efficient in the hands of the writer does not seem to be clearly understood by the majority of operators, and I therefore take this opportunity to explain its many merits and advantages.

It should be distinctly understood at the outset that no one method is equal to all the requirements of every case, for the deformities of the sæptum are so infinitely varied that such a claim for any one method would be as absurd as it would be to attempt to make one tool or implement do every kind of mechanical work.

Classification.—To classify all the numerous malformations to which the sæptum is liable is well nigh impossible. The frequent designation of different deflections of the sæptum by the terms "zigzag," "sigmoid," "letter S," "angular," "ridged," "bowed," etc., which apply to the shape of the deflection alone, are quite inadequate, for they simply describe the conformation of the deflection, without reference to its location, whether it be in the cartilaginous or osseous portion.

The only classification, therefore, which, from an anatomical standpoint, is at all satisfactory, is that made with reference to the anatomy of the sæptum as first proposed by Jarvis. According to this classification, therefore, we have: First, deviations of the osseous

* Read before the Twenty-Second Annual Meeting of the American Laryngological Association, Washington, D. C., May 3, 1900.

portion—that is, the perpendicular plate of the ethmoid and vomer, either alone or combined; secondly, devia-

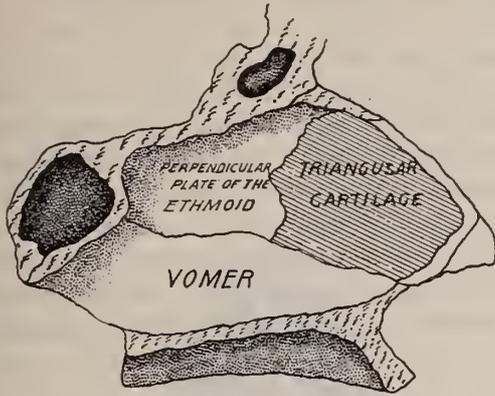

FIG. 1.—Showing the component parts of the sæptum.

tions of the cartilaginous portion—that is, the triangular cartilage; and, thirdly, a deviation of the osseo-cartilaginous portion, comprising the anterior part of the perpendicular plate of the ethmoid and the posterior part of the triangular cartilage, the anterior superior portion of the vomer and the lower border of the triangular cartilage, the region where these different portions are joined (Fig. 1).

Figs. 2, 3, and 4 are diagrammatic illustrations of a horizontal section through the centre of the sæptum, the length of the osseous and cartilaginous portion being at this point about equal. If the section were through the lower border of the sæptum it would be almost entirely bony, owing to the forward prolongation of the anterior portion of the vomer. In some instances there may be a combined deviation of the entire sæptum, termed "bowed sæptum" (Fig. 5), when it describes one long curve, both vertically and anteroposteriorly, from one end to the other. Other classifications, therefore,

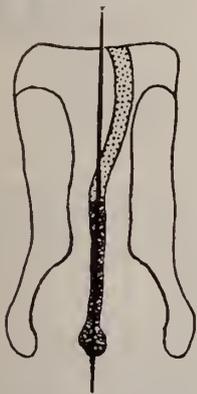

FIG. 2.—Deviation of the posterior portion of the vomer.

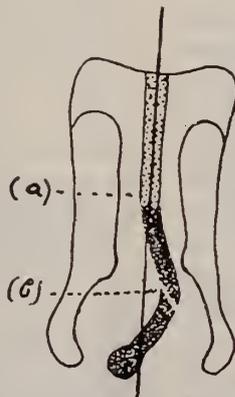

FIG. 3.—Deviation of the triangular cartilage, with dislocation at its columnar attachment.

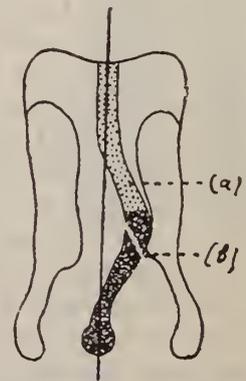

FIG. 4.—Deviation of the osseocartilaginous portion.

(a) (a) The osseous portion to be fractured in changing the direction of the deflection of the cartilage. (b) (b) The oblique line of incision through the cartilage.

need not be considered. Such conditions as exostoses (Fig. 6) or encondromas (Fig. 7), located on one side of the sæptum only, which give the sæptum on that side the appearance of being deflected, demand attention here only when associated with deviations of the sæptum requiring correction.

Frequency with which Different Portions are Deviated.—With reference to the frequency with which these different portions of the sæptum become distorted, it is found that the posterior part of the osseous portion is but rarely deviated alone; and even when occurring in connection with that of the other portions of the sæptum, it is found in only about five per cent. of cases.

Next in frequency comes the deviation of the cartilaginous portion alone, found in about twenty per cent. of cases; whereas the osseo-cartilaginous portion (the junction of the perpendicular plate of the ethmoid or of the vomer with the triangular cartilage) is found deviated in about seventy-five per cent. of the cases coming under observation. Twenty per cent. is a very liberal estimate for the frequency of the deviation of the triangular cartilage alone; for when the deviation is confined to the anterior half of the sæptum, the anterior portion of

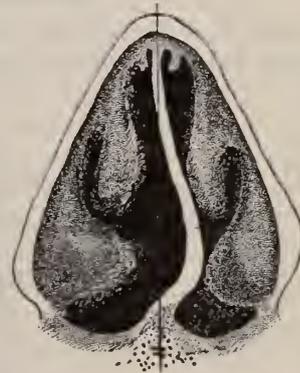

FIG. 5.—Deviation termed bowed sæptum.

the perpendicular plate of the ethmoid and of the vomer are in most cases deviated with it.

Thus it is readily seen that a method adapted for the correction of deviations of the cartilaginous portion of the sæptum alone should be employed in but twenty

per cent. of the cases, while a method specially adapted for the correction of deviations of both the osseous and osseo-cartilaginous portions is required in eighty per cent. of all deviations of the nasal sæptum.

The Writer's Method and the Principles on which it is Based.—The method which the writer has found to

meet these requirements is one which he has employed for ten years, and which he presented before this association nine years ago.* It is one that meets the dif-

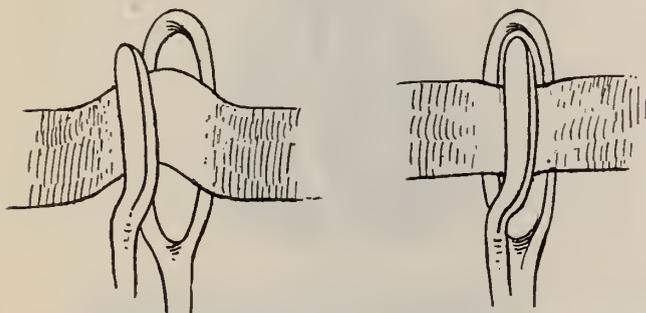

FIG. 6.—Illustrating exostosis of the sæptum.

FIG. 7.—Illustrating echondroma of the sæptum.

ferent requirements in the greatest number of cases, needing, in a limited number of cases only, to be supplemented by other methods or by the use of special instruments suited to deal with certain particular and localized conditions.

This method is based on the principles of a force being applied to one side of the sæptum, indenting it between two opposing points of resistance placed on the

FIGS. 8 and 9.—Diagrammatic illustrations of the application of the principle of the fenestrated forceps in fracturing a deviated sæptum.

opposite side, as illustrated diagrammatically in Figs. 8 and 9.

Description of the Instrument and Method of Using It.—The application of the foregoing principle to deviations of the sæptum is made by means of a fenestrated forceps, one blade of which is made in the form of an ovate ring, termed the “ring, or female blade,” and the other made in the form of a long, narrow, rounded blade, termed the “single, or male, blade” (Fig. 10); the latter fitting loosely into the former, so as not to unduly compress or lacerate the sæptum. The blades are attached to the handle by a curved neck, or stem, sufficiently long to pass around the frenum of the nostril so as to avoid compressing it when the force of the blade is applied to the sæptum. The forceps is made with blades of different sizes to meet the requirement of different-sized nasal passages or sæptum, or deflections, as the case may be.†

*Transactions of the Thirteenth Annual Meeting of the American Laryngological Association, 1891; also Transactions of the Fifteenth Annual Meeting of the American Laryngological Association, 1893, page 83.

† To simplify the instruments the necessary blades of different sizes are made separately and fitted to one handle, which George Tiemann & Co. have very admirably put up for me in one case, together with the other instruments to be used in connection therewith.

On straightening a deviated sæptum, the male blade is inserted into the nostril on the convex side of the deflection and the ring blade on the opposite side (Fig. 11), when, by closing the blades, the deflected portion is crowded into and partly through the opening far enough to forcibly indent the central portion and fracture it without disturbing or bringing a strain on other portions of the sæptum. The distance to which the single blade is forced into the ring blade is governed by a set screw in the handle, and the extent to which it should be allowed to pass into the ring blade is governed by the thickness of the sæptum, the position and degree of the deflection, and the size of the blades employed.

In straightening a deviated sæptum, no matter if

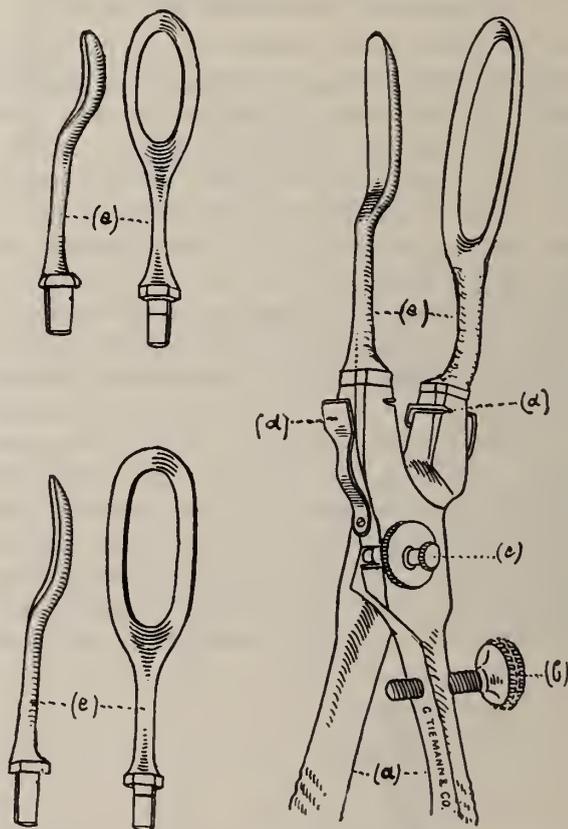

FIG. 10.—Showing the various parts of the instrument. (a) the handles with blades attached; (b) the set screw for regulating the adjustment of the blades; (c) lock permitting the handles to be detached from each other; (d) spring catch for holding the blades firmly in the handle; (e) (e) (e) blades of different sizes that fit into the handle.

the deflection is confined to the cartilaginous portion alone, it is of the utmost importance that the bone at, or adjacent to, the attachment of the cartilage be fractured. By so doing, the change in the direction of the attachment of the cartilage is made in the bone (a, a, Figs. 3 and 4), so that, so soon as the fractured bone is reunited and becomes firm, it permanently holds the cartilage in its new position. With this point made clear, the superiority of the ring forceps over the flat-bladed forceps, like Adams's forceps, must at once be apparent.

With flat-bladed forceps it is only possible, except by twisting the blades, to bring the bend in the sæptum up

to the median line, which never suffices to fracture the cartilage, and but seldom the bone, and then only when the bend in the bone is so great, and the blade of the forceps sufficiently wide, to bring a large amount of force to bear at the centre of the angle. As it is only by twisting the forceps that a fracture of the bone can be brought about, it is readily seen that, the moment the blade is twisted, the sæptum must either be lacerated or loosened at its attachment, to accommodate the greater

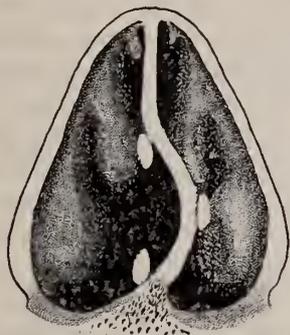

FIG. 11.—Showing in outline the position of the blades in fracturing the sæptum.

distance of the line through the centre between the blades; whereas, by means of the fenestrated forceps, very little force is required and no strain is brought to bear on adjacent portions of the sæptum, and the line of the contour of the deflection is made shorter by having the angle or bent portion crowded into the fenestrated blade, as illustrated diagrammatically in Figs. 8 and 9.

By this method, therefore, the well-known dangers recognized as attending the fracture of the vomer by flat-bladed forceps (like the Adams forceps, which requires twisting and wringing of the forceps, causing laceration of the parts, possibly disturbance of the upper attachments of the perpendicular plate of the ethmoid, and brain complications) are avoided. By this method, also, by the selection of proper-sized blades, the fracturing of the sæptum can be limited to the deflected portion only, or to any part desired, without disturbing the other portions of the sæptum.

This method, while especially adapted, as I have said, for the correction of deviation of the osseous and osseocartilaginous portions, is also of service in cases of moderate deviations of the cartilaginous portion alone, by simply fracturing the adjacent bone around the deviated cartilage and forcing the central deflection of the cartilage into the fenestrated blade. With this instrument, also, the cartilage can usually be fractured sufficiently to overcome the elasticity without the necessity of incising or lacerating it, and this can be accomplished by no other method with which I am acquainted. Then, by holding the sæptum in position by a support placed in the previously occluded side for a few days, until sufficient inflammatory exudate has been thrown out or ossification of the fractured bone has taken place, so as to maintain the angle of the deflection in its new and straightened position, the necessity of maintaining a sup-

port to the sæptum for a considerable time, until the resistance or elasticity is overcome by prolonged pressure, as generally advocated, is avoided.

Providing for Redundancy.—It is self-evident that a deflected sæptum is larger or wider and longer and has a greater extent of surface than a straight one. But, on straightening the sæptum, much of this redundancy of the cartilaginous portion can be accommodated by the mobility and flexibility of the cartilaginous portion of the dorsum of the nose and of the lower portion bounded by the frenum; whereas, in the osseous portion, the redundancy is accommodated by the impaction and crowding together of the fragments, if sufficiently comminuted by the forceps. When, however, the bend in the cartilaginous portion is large, it is not only advisable, but often necessary, to provide for the redundancy by incising the cartilage in order to allow the severed portions to slide past each other.

Methods of Incising the Cartilage to Provide for Redundancy.—The method of incising the sæptum that has given me the most satisfactory results, is by making the incisions oblique, so that the ends of the fragments will slide past each other like two wedges (Figs. 12 and 13), and at the same time permit a portion of the cut surfaces to remain in apposition for union to take place.

The greater the redundancy, and the more acute the angle of deflection, the greater will be the lapping at the end, and, accordingly, the incision should be correspondingly more oblique, to permit the proper coaptation of the cut surfaces. When the deflection is horizontal, forming a ridge on one side and a corresponding groove on the opposite side, the incision should be hori-

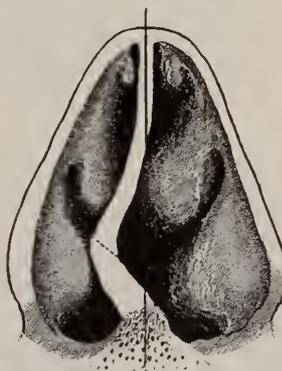

FIG. 12.—Showing the oblique incision longitudinally through the cartilage.

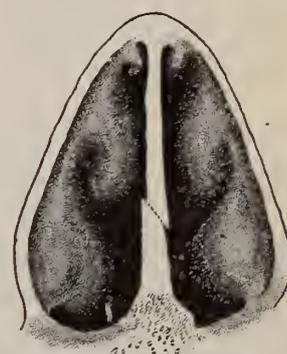

FIG. 13.—Showing coaptation of the cut surfaces after the sæptum has been straightened.

zontal only. When this groove and ridge run up and down through the centre of the cartilage, the incision should be vertical; but when the deflection consists of the combination of a vertical and a horizontal bend, so as to make it somewhat conical, as if a pressure had been applied at one point, indenting the sæptum, the incision should be both vertical and horizontal (*a, a* and *b, b*, Fig. 16), and each should be made through the sæptum obliquely and along the direction of the axis of the greatest bend or convexity. The incision of the car-

tilage should be made from the convex side with a small nasal cartilage knife (Fig. 14), with the finger in the opposite side, or in free nostril, for a guide. In order to make the incision oblique, the use of the knife is neces-

sired only to change the directions of the angle or to overcome the resistance or elasticity of the cartilage, the elevation of the perichondrium is unnecessary.

In this way a wound of the mucous membrane in the concave side of the sæptum is avoided, obviating the necessity of obstructing the nostril with any form of dressing, as the support of the fragments is maintained entirely from the previously obstructed side.

Before the incisions are made, the sæptum should be carefully explored to ascertain the amount of thickening, and whether ridges, spurs, or adhesions, are present, requiring removal, before the straightening is undertaken. This can be much facilitated by the use of suprarenal extract and cocaine. Frequently, and especially if the turbinated bodies are enlarged or the sæptum so much deflected as to obscure the vision of the convex side, the use of a small nasal sound, or of the sæptometer, will be required. Frequently, however, the most accurate information can be obtained by exploration with the finger, which, if well oiled, is readily introduced into the concave side, and the yielding nature of the cartilage and turbinated bodies will permit the little finger to be crowded well into the convex or occluded side.

In some cases the nature of the deflection may be such that all the spurs or ridges on the cartilaginous or bony portion cannot be readily removed before the operation. In such cases the sæptum can be straightened first and any irregularities that may remain removed afterwards.

The Operation for Straightening the Sæptum.—After the preliminary operations for excrescences or redundancies have been performed and any necessary incision made, the fenestrated forceps, with blades of suitable size, is introduced, with the ring or female blade on the concave side of the sæptum, the male blade being

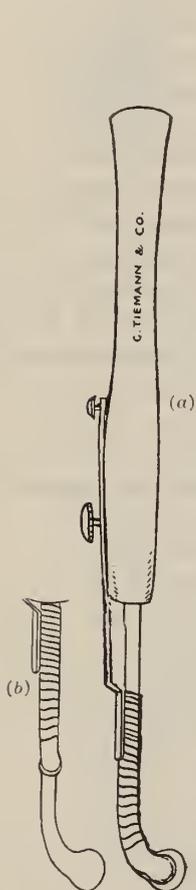

FIG. 14.—(a) Nasal cartilage knife, having a shield for regulating the depth of the incision when it is not desired to cut entirely through the sæptum; (b) shield thrown back when not required.

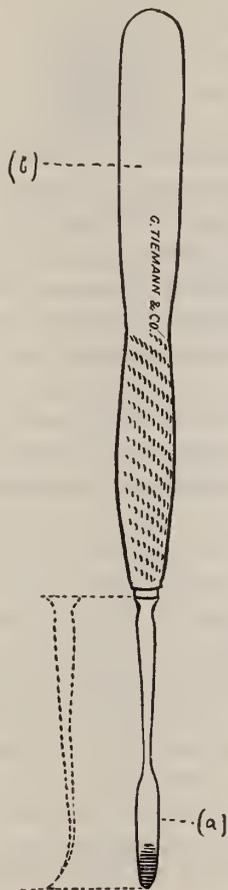

FIG. 15.—Perichondrium elevator and sæptum spatula combined. (a) Perichondrium elevator; (b) Sæptum spatula for putting the sæptum in line after the use of the forceps.

sary, for with cutting scissors it is possible only to make the incision at right angles to the plane of the sæptum.

On making the incision, if it is to be horizontal, the knife should be passed in carefully to the further point of the convexity and the cut made on drawing the knife forward; if a vertical incision is to be made, the knife should enter at the upper portion of the bend and the cut be made downward. In many cases it is necessary only to make the incision through the cartilage to the under side of the perichondrium on the other side. This can be done very readily with the finger on the opposite side of the sæptum, when, by the careful use of the knife, the approach of the blade can at once be detected as it passes through the cartilage. The perichondrium can then be raised for a short distance from each inner edge of the cut surfaces sufficiently to allow the upper fragment to slide under. This can very readily be done with a small elevator made for that purpose, as represented in Fig. 15 (a), which is passed through the incision and directed by the finger in the free nostril. In other cases, when the deflection is moderate in degree and it is de-

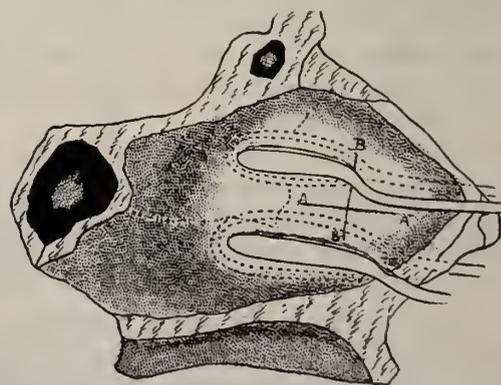

FIG. 16.—Showing the application of the forceps in fracturing different portions of the sæptum. A A and B B, horizontal and vertical incisions through the cartilaginous portion of the sæptum.

very readily crowded into the obstructed nostril on the convex side (Fig. 11). The forceps is so constructed that the blades are separable like those of an obstetric forceps, which is readily locked after the blades have been introduced. When the blades are in proper position, the lower portion, or the junction of the cartilage with the anterior portion of the vomer, should be fractured; then

the junction of the cartilage with the perpendicular plate of the ethmoid, so that all the resistance or elasticity has been entirely overcome.

In the selection of the blades in each particular case, it should be made with reference to the size or length of the deflection. In some cases, however, the deflection in the osseo-cartilaginous portion will be very much greater than the size of the meatus, so that a ring blade large enough to cover the deflection cannot be introduced, in which case a portion of the deflection can be broken up at a time, the position of the forceps being changed, or different-sized blades selected according to the site of the part to be fractured (Fig. 16), and new portions of the deflection grasped until the deflected portion has been sufficiently broken up and the elasticity removed to allow it to be placed in the median line.

In many cases there is a deflection or dislocation of the triangular cartilage at its attachment with the vomer, associated with a dislocation or deflected attachment of the vomer itself along the maxillary ridge. This can ordinarily be corrected by forcibly holding the forceps down to the floor of the nose, as shown in Fig. 17, and, by catching the lower portion of the ring blade over the stump of the maxillary ridge, a sufficient

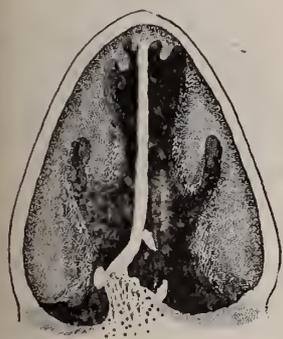

FIG. 17.—Dislocation and deflection along the maxillary ridge, and the application of the forceps in correcting it.

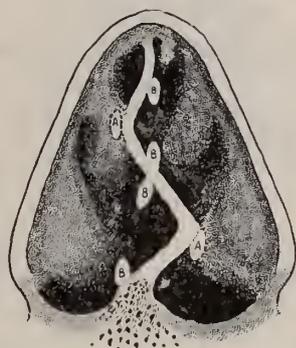

FIG. 18.—Zigzag deflection, showing how the forceps is reversed in correcting it.

pressure can be brought by the single blade to fracture the attachment and set the sæptum over to its proper position. In case ossification is too firm, the operation can be facilitated by loosening with the chisel or saw the bone at its lower attachment.

When there is a double deflection, forming a "zigzag," or "sigmoid," deflection, the centre of which is usually found along the line of the attachment of the triangular cartilage with the perpendicular plate of the ethmoid, it is necessary to reverse the blades of the forceps for the two sides, forcing one portion over in one direction and the other portion over in the opposite direction, as shown in Fig. 18. But, owing to the occasional difficulty in some cases of maintaining the parts in position after a double operation, it is frequently advisable to make each deflection a separate operation, the second one being performed when the parts are thoroughly fixed in place after the previous operation.

After the forceps is used, and before the dressing or

support is introduced, the sæptum should be carefully explored with the small nasal spatula, as shown in Fig. 15 (b), or with the finger, to ascertain if all the elasticity of the fractured portion has been overcome. If any elasticity still remains, this should be overcome by the use of the forceps at the point of resistance.

When this has been accomplished, the sæptum should be put in the median line preparatory to the introduction of the dressing. For this purpose the nasal spatula or perichondrium elevator is admirably adapted, although in many cases the flat-bladed Adams forceps, having parallel blades, is exceedingly serviceable for putting the fragments and the entire sæptum exactly in the median line.

Method of Dressing or Support.—Among the various devices for holding the sæptum in place, I have found no support so satisfactory, and at the same time so thoroughly aseptic, as a plug made of sterilized cotton or gauze wrapped around a small metal plate to give it firmness, and of the requisite size to fill the nostril comfortably. This is placed in the previously occluded nostril or the convex side toward which the sæptum has been deflected. In case there has been a double deflection, one should be placed on each side, opposite the point of previous convexity; the other nostril, or the formerly concave side, where no support is necessary, being left free for respiration.

The advantage of this form of support over the hard-rubber tube or the various other mechanical appliances that have been devised for this purpose, is that the nasal passages can be made and maintained thoroughly aseptic, which is impossible when these other appliances are used; and, moreover, the healing of the wound is not only more readily promoted, but the danger of erosion of the wound, thereby preventing healing and endangering hæmorrhage, is entirely avoided.

Simpson's Berney's compressed cotton tampons, if they have been sufficiently sublimated previously to compression to maintain them thoroughly aseptic, are an ideal dressing for this purpose; although care will have to be exercised lest too large a sponge be selected, that may, after becoming wet and expanded, force the sæptum over beyond the median line.

Preparation of the Parts for the Reception of the Dressing.—Before a dressing or support is introduced, and, in fact, before the operation is undertaken, the nasal passages should be thoroughly cleansed by syringing with a warm boric solution, 1 to 5,000, and after the operation has been performed they should be again thoroughly cleansed with the same solution. The parts are then dried with sterilized cotton, dusted with an antiseptic powder, as iodoform or urophen, and the dressing introduced. The dressing, however, before introduction, is saturated with the bichloride solution, to which may be added a small amount of tannin to check any prolonged oozing of blood, which sometimes takes place when spurs have been removed and other

cutting done preliminary to the operation of straightening the sæptum. If the nostril and the dressing have been made thoroughly aseptic and the dressing carefully and properly inserted, it can, if of cotton, be left *in situ* for from three to four days before removal. It can then very readily be removed without pain or discomfort by slightly dazing the patient with a few whiffs of chloroform. The nasal passage is then thoroughly irrigated with the bichloride solution, anæsthetized by cocaine, and a fresh plug similar to the previous one introduced. This is left *in situ* for two days longer and removed.

By this time the sæptum is usually self-supporting, sufficient provisional callus or inflammatory exudate having been thrown out to render the parts rigid enough to require no further support. It is, however, advisable to watch the sæptum, to see that there is no sagging back, necessitating further support for a few days longer. If it is necessary, a hard-rubber or aluminum tube can now be used to advantage. It should be entirely smooth and without perforation, which can serve no purpose except to afford a lodging-place for discharges to decompose in.

Local and General Anæsthesia.—In performing the operation for deviated sæptum in children, the use of general anæsthesia, preferably chloroform, is always necessary, and usually in timid adults also, although in many cases it can be performed by the use of local anæsthesia alone.

Usually, with adults, I do all the preliminary work under cocaine, aided by suprarenal extract, and then, with the whole sæptum thoroughly anæsthetized, a small

FIG. 19.—Exostosis and enchondroses at angles of deflection with enlarged turbinated bodies.

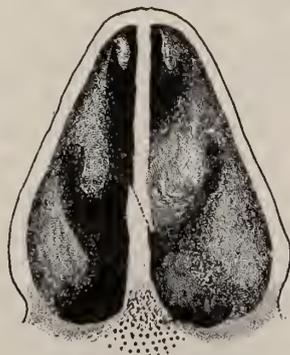

FIG. 20.—Showing transfer of obstruction by straightened sæptum in Fig. 19, if enlargement of turbinated bodies is not removed.

amount of chloroform, a few whiffs, is given, just sufficient to daze the patient while the fracturing is being done. For the other portions of the operation, chloroform is entirely unnecessary, and no pain or special discomfort should be experienced by the patient.

We may briefly summarize the *modus operandi* of straightening a deviated sæptum by this method as follows:

After the extent and position of the deflection has been clearly ascertained, the special plan of operation required in each particular case is determined upon.

If we find in the passage on the concave side of the sæptum a greatly enlarged middle or inferior turbinated body, as we frequently do (Figs. 12 and 19), this should be reduced to its normal dimensions, and the parts healed, before the operation is undertaken; otherwise, we would simply transfer the nasal obstruction to the opposite side by straightening the sæptum, as shown in Fig. 20.

If we find an exostosis or an enchondroma (Fig. 19) at the angle of the deflection on the convex side, as we usually do, this should first be removed with a saw, trephine, or cartilage knife, as the case may require.

If the deflection is confined to the osseocartilaginous portion alone, or is associated with deviation of the cartilage, by fracturing the osseocartilaginous region, so as to change the angle of the attachment of the cartilage, and holding it in place until healed, the deformity can be readily corrected.

If the deviation is confined to the cartilage alone, by fracturing the osseocartilaginous portion it can readily be put in the median line.

If the deviation of the cartilage is concave or indented, fracturing or incising the cartilage itself may be necessary.

If moderate in amount, simply incising the cartilage from the convex side through the point of greatest convexity to the perichondrium on the opposite side, under the guidance of the finger in the free nostril, so as to destroy the elasticity of the cartilage, may be a sufficient supplement to the osseocartilaginous fracture.

If the deflection in the cartilage is so large that the redundancy must be provided for, more extensive incisions through the cartilage are necessary. These should be made obliquely, either entirely through the sæptum to permit the cut ends to slide past each other (Figs. 12, 13, 19, and 20), or only to the perichondrium (Fig. 21), which is raised from one edge for a distance sufficient to allow the other edge to slide under as the case may require.

With these preliminaries completed, the sæptum is fractured and put in the median line, the parts made aseptic, the dressing or support introduced, and the sæptum maintained in the median line until ossification and fixation of the parts have taken place.

If the operation has been carefully and properly performed and all elasticity or resistance at the seat of the deformity has been thoroughly overcome, a support for five or six days, until fixation of the parts by plastic exudate has taken place, is, in ordinary cases, all that is or should be required.

Later, when the sæptum has become firm and the healing process completed, any slight irregularities can be trimmed off, leaving the sæptum on both sides straight and smooth, without concavities or depressions to serve as a lodging-place for mucus or other discharges.

Without detracting from the methods of others,

which in many cases are admirable for the correction of the particular deformity to which they are specially adapted, I shall briefly summarize the special advantages that can be claimed for the superiority of this method over other methods for the correction of the various deviations of the sæptum.

First. The facility and ease with which, in every instance, the osseous and osseocartilaginous portion of the sæptum can be fractured and all resistance removed without incising, or even lacerating, the sæptum, may be noted.

Secondly. By fracturing the anterior portion of the osseous sæptum and changing its direction by putting it in a straight line together with the cartilaginous portion, so that, when this osseous portion becomes reunited in its new position and firm ossification has taken place, the cartilaginous portion is firmly held in its new position. As osseous tissue does not readily bend, this must necessarily act as a firm post or sup-

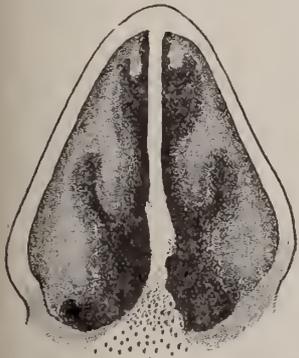

FIG. 21.—Showing bulging of mucous membrane after straightening the sæptum when the perichondrium has been raised at the time of the incision of the cartilage.

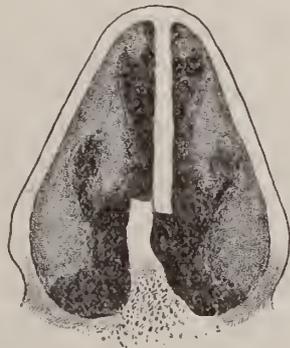

FIG. 22.—Lapping of the cut surfaces after straightening the sæptum when a right-angle incision had been made.

port, to hold the cartilage in its new position, very much in the same manner as the direction of the hang of a door is changed at its hinges, as illustrated in Figs. 3 and 4.

Thirdly. Moderate deflection of the cartilaginous portion of the sæptum can also be fractured with the forceps and the elasticity overcome, without the necessity of incising the cartilage.

Fourthly. By this instrument, wrinkles and curves can very readily be smoothed out, no additional operative measures being required, except for the removal of spurs and ridges or the breaking up of adhesions or attachments that may have previously formed.

Fifthly. By this method, dislocations of the triangular cartilage at its articulation with the vomer, or dislocations of the latter at its maxillary attachment, can very readily be reduced and the parts put in their normal position. By this method, also, except in rare cases, the extensive incisions proposed by different operators are obviated; such as crucial or rectangular incisions with cutting forceps; the horseshoe incisions through which the deflected portion is pushed, which cannot be of spe-

cial service except in limited indented deviations of the triangular cartilage; or the separation and setting over of the base of the sæptum into the free nostril far enough to leave both nasal passages of equal calibre, which simply compensates for the bend in the sæptum, without straightening it after all.

Sixthly. In those cases in which incision through the cartilage is required to provide for the redundancy, the superiority of the oblique incision, which promotes coaptation of the cut surfaces, over the right-angled incision, which does not, is at once apparent (Fig. 22).

Finally. The superiority of the fenestrated forceps over the flat-bladed forceps or the fingers, as proposed by some operators, for breaking up of the base of the fragments at their bony attachments, is apparent. It also obviates bringing strain on the sæptum and disturbing its upper attachments, thus endangering brain complications, and by completely removing the elasticity of the attachments of the deflected parts, it facilitates the more ready adjustment of the sæptum to its normal position and diminishes to a minimum the length of time a support to the sæptum is required.

THE PATHOLOGY OF INTRA-UTERINE DEATH.

By NEIL MACPHATTER, M. D., C. M., F. R. C. S.,

NEW YORK,

VISITING SURGEON, POST-GRADUATE HOSPITAL.

(Continued from page 587.)

Fatty Degeneration of the Placenta.—As a primary affection, true fatty degeneration of the placenta must be considered a rare disease, and as analogous to fatty changes taking place in other organs of the body. The occurrence of this condition presupposes an impaired vitality of cell protoplasm. The vital activity of these cells becomes depressed, gradual or rapid destruction of their protoplasm ensues, and eventually the oxidizing power is crippled or entirely destroyed. The first essential for fatty degeneration to become possible is found in the altered quantity and quality of the blood brought to the cells of the placenta. This gradually changes the character and physical condition of these cells. This being so, it is natural to suppose that fatty degeneration of the placenta results from various forms of anæmias, blood dyscrasias, and defects of the umbilical cord. The degenerative process is most frequently found in the villi and their immediate neighborhood. It is extremely probable that during the formation of the chorion a greater number of villi are developed than is afterward found to be required. The useless villi atrophy by a process of fibro-fatty degeneration, in consonance with a general law of Nature. It is possible for this process to become more active than the necessities of the case demand, and to extend to surrounding villi. Compression, and even total obliteration, of a large area of active villi

may follow. In this manner the function of the placenta as a supplier of nutrition is impaired or entirely abrogated, and the fœtus dies by a slow process of starvation. When the disease is not extensive, the child may be born alive, but of a low order of vitality and lacking in the attributes of a healthy, normal child. Considerable confusion has arisen in the minds of medical men in regard to the frequency of this disease. They have confused fatty degeneration as a primary affection with fatty metamorphosis following on the death of the fœtus, as the result of some other disease. If a distinct line were drawn between these two processes, it would probably be seen that true fatty degeneration of the placenta was not nearly so frequent a disease as has been stated by some writers. It sometimes happens that when a fœtus perishes it is not immediately expelled from the uterus. In such a case an effort is immediately initiated to cause its absorption. The first stage in this process is a degeneration into fat, which is then amenable to absorption. It is quite probable that the detachment of the membranes from the uterine wall at the end of pregnancy is affected by fatty degeneration. This can readily be seen on making a careful examination of the placenta immediately after normal labor. This is more apparent in the membranes and round the edges of the placenta. The condition is probably not a true fatty degeneration in the sense that we apply the term to the process generally. It is Nature's method of liberating the placenta and membranes from their attachments. It would seem that this separation is brought about gradually, for the nutrition and respiratory functions have to be maintained until the complete termination of pregnancy.

Edema.—The placenta is sometimes affected by dropsical enlargement. When at all extensive, the condition can readily be detected. Usually the placenta is considerably larger, more friable, and of a paler color than normal. The effect upon the child varies according to the extent of the disease. When the disease is at all extensive the child perishes long before the termination of pregnancy. Should it survive, the body will be poorly nourished, and there may be evidences of dropsical effusions into the cellular tissue. Just how this peculiar condition is brought about is somewhat difficult to determine. Barnes, who devoted considerable time and attention to its pathology, found, associated with it, hydræmia, anasarca, Bright's disease, and valvular affections on the part of the mother, and dropsy on the part of the child. Other authorities suggest that it is due to some obstruction to the circulation through the umbilical cord. It is usually in the villi that the infiltration first appears. They become dilated and cystic, but this condition should not be confounded with cystic degeneration of the villi already described.

Calcareous Degeneration.—Calcification of portions of the placenta or membranes is sometimes found. The subject is an extremely interesting one from the fact

that it may seriously interfere with the life of the fœtus. The condition is a purely passive one, for the cells take no active part in the process. The parts are gradually petrified by deposits of the earthy salts continually circulating in the blood. These salts cannot affect healthy tissue injuriously, but once diminution or extinction of vital activity takes place, salts become deposited in its substance. In the circulation these earthy salts are in solution, and consist chiefly of phosphates and carbonates of calcium and magnesium. The solvent is probably carbon dioxide. The condition is a very frequent one as a senile change. Calcareous degeneration may become quite extensive. When speaking of ectopic pregnancy, it was then stated that the whole fœtus sometimes became completely calcified. It is then known as a lithopædion. The deposits are more frequently found in the decidua membrane than in the placental substance. Stellated and irregular patches of calcareous deposits can be felt or seen on the decidua surface. Sometimes they are hard, round, and gritty; more frequently they are flat and amorphous. They can be scaled from the decidua surface quite readily. They are not limited to the decidua membrane, but appear to follow into the intercotyledonary spaces and into the villi. Occasionally the whole placenta appears to become affected. Decker and Millet, as quoted by Ercolani, found a placenta studded with chalky deposits to the number of more than two hundred. The fact that the disease so frequently begins in the decidua surface would indicate that this membrane was not in a healthy condition when impregnation took place. Chronic endometritis previous to pregnancy would lower the vitality of the cells sufficiently to permit the deposit of earthy salts. The placenta becomes intimately adherent to the uterine wall, and frequently is quite difficult to remove. The disease is more frequent toward the end of pregnancy, and, for this reason, many of the older writers maintained that it was an indication of over-ripeness or prematurity of the afterbirth. By examination, the condition can be more readily recognized by touch than by sight. When the particles are small they feel like fine sand between the fingers. All degrees between this and hard, stony masses can be found. When the disease is in any way extensive, the nutrition and respiration of the fœtus are seriously interfered with, and the child may die by a slow process of starvation or asphyxiation, or both. Should it survive, it would be ill-nourished and puny, and liable to live but a short time. The disease is not limited to any particular class of women. For a time it was thought to be associated with scrofula, tuberculosis, anæmia, poor living, and allied diseases, but these are probably not the exciting causes or starting points of this disease. It is frequently found in the placenta of women who are unusually healthy and robust.

Myxoma Fibrosum.—This disease was first described by Virchow, and consists of a fibroid hypertrophy of the villi and their stems. These enlargements are not uniform, but bulge out into distinct tumors in many parts

of the placental structure. The disease is somewhat rare, but is of sufficient importance to interfere seriously with the function of the placenta, when present.

The tumors vary in size from that of a pea to that of a hazelnut. They are attached to the main trunk by stems of varying length. When an incision is made through into the centre, the hard nodular mass bulges out of the capsule. They originate from the central part of a villus. When speaking of diseases of the decidua, it was there stated that the central, or parenchymatous, part of each villus was composed of mucus. This disease is to be regarded as a transformation of this mucus into fibroid tissue. It is much more frequently found toward the later months of pregnancy, and in this respect differs from cystic chorion. Some of the cases of sarcoma of the placenta are probably in reality instances of the central part of a villus degenerating into fibroid substances. When the disease is limited a viable child may be born, although emaciated and puny; if, on the other hand, an extensive area is involved, the child, of necessity, perishes.

Cystic Disease.—Several authors have described certain neoplasms found in the placenta and between the various membranes as cystic in character. They are obviously not true cysts, as we understand the condition. Frequently they are the remains of broken-down blood extravasations, found embedded in the substance of the placenta; or, what is equally common, between the chorion and amnion. When in the latter situation, they may attain a considerable size. Sometimes they are found to be composed of coagulated fibrin, evidently the result of a previous inflammation. Ercolani describes a case in which the contents were composed of pultaceous matter, evidently fat granules, and disintegrated fibrin. The wall was constituted of a large number of small, calcareous concretions and fibrous laminæ. These are quite rare, and but seldom interfere with the integrity or function of the placenta.

Syphilitic Placentæ.—All authorities agree that syphilis is one of the most potent influences in the death and destruction of the fœtus. It is important, therefore, to appreciate what effect this disease may produce upon the substance of the placenta. In looking through the literature of this subject, it is found that considerable diversity of opinion exists upon many points of this important matter. There are many standards given as to what constitutes a syphilitic placenta. The majority of them do not agree. It is an extremely difficult task, if not an impossible one, to state exactly what constitutes a syphilitic placenta. No two cases of syphilis affect their victims in a similar manner. There are all gradations in the virulence of the initial lesion, as there are all degrees in the resisting forces of the constitution. What makes the question more complicated, when applied to the placenta, arises from the fact that the placenta is composed of two distinct parts, one originating from the mother and the other from the fœtus. When speaking

of general constitutional conditions affecting the well-being of the fœtus, it was then stated that the influence of syphilis upon the fœtus depended largely upon the virulence of the type and whether the condition was transmitted from the mother or father. The effect of syphilis upon the placenta will also vary according to the severity of the disease, but more especially according to whether the male or female parent is responsible. These are general rules, but it must not be forgotten that occasionally idiosyncrasies occur in this disease as in others. Some authorities regard enlargement and thickening of the walls of the arteries in the fœtal portion of the placenta as characteristic of syphilis. There is no doubt that this condition is very frequently present in syphilis, but other diseases are sometimes associated with enlarged and thickened arteries. Virchow maintains that, in the elucidation of this subject, it must not be forgotten that the placenta and membranes consist of a maternal and a fœtal portion. According to him, syphilis during pregnancy produces two varieties of endometritis. The one exerting the greatest influence affects that part of the decidua which enters into the formation of the placenta. From this point the inflammatory action frequently extends to the villi, and causes them first to undergo a fibroid hypertrophy and afterward an atrophy. The second form of endometritis affects principally the decidua vera. This membrane becomes soft, thick, and swollen from vascular proliferation, but it would seem that it does not subsequently undergo fatty or other degeneration. Some doubt has been thrown on the accuracy of this theory of Virchow's by Strausmann and others, who found the same conditions present in women who had not the least trace of a venereal taint. Fränkel made a careful examination upon more than one hundred placenta in the pursuit of a typical syphilitic placenta. His conclusions are extremely interesting. The placenta from which he carried out his investigations were those belonging to syphilitic children, and he affirms that a syphilitic placenta has definite characteristics by which it can be recognized. The evidence varies according to whether the virus of syphilis was supplied to the placenta by the father or the mother. When the syphilis is derived from the father, the effects are chiefly centred in the fœtal part of the placenta. They are not, however, limited to this region, but frequently extend to the decidua. The villi become much enlarged, the epithelial covering undergoes great proliferation, and their shape becomes greatly distorted. The blood-vessels are much engorged, tortuous, and the coats considerably hypertrophied. The placenta are usually considerably larger than normal. As pregnancy advances, the condition of hypertrophy gives way to atrophy. The blood-vessels are in many places entirely obliterated, the epithelial covering fully disintegrated, and then fatty degeneration sets in.

When the syphilis is derived from the mother, it is the maternal portion of the placenta that is primarily

affected. By contiguity of surface, the disease soon involves the villi or foetal portion. In these cases the decidua becomes enormously enlarged, and eventually compresses and crushes the villi so as to interrupt their function. The consequence is that the placenta soon ceases to be a medium of nutrition and respiration, and the child perishes. When both father and mother are syphilitic before pregnancy, the maternal and foetal surfaces of the placenta are equally affected, and the change produced will, of necessity, be a mixed one. There is a general tendency to small hæmorrhagic patches in the more affected areas, and the color frequently varies from a light gray to dark brown or black. Priestley's investigations upon this subject coincide with these views so closely that I will here reproduce them in his own words: "I have on different occasions had the opportunity of examining placenta in the early months of gestation with certain peculiarities of morbid change which I considered were undoubtedly due to syphilis. For example, I examined the placenta in two separate pregnancies of the same individual. She had contracted syphilis immediately after her marriage, and at the same time became pregnant. During the early part of her pregnancy the vulva became the seat of specific sores, mucous tubercles, and warts. Later, her body was covered with patches of syphilitic psoriasis. She miscarried in both the first and second pregnancies in the fifth month. Both the placenta exhibited changes very closely resembling each other. On the uterine side of the placenta the decidua was much thickened, and there was great increase of all the cellular and fibroid structures which normally constitute that membrane. Prolongations of this dense tissue were sent down into the substance of the placenta and seemed to terminate about half way through its thickness. The effect of this dense layer was apparently to compress and contract the sinuses or lacunæ, to do away with the spongy character of the organ, and so to prevent the growth of the villi into the sinuses. The villi next to this layer were stunted and atrophied. Those near the foetal surface were hypertrophied and were beginning to undergo fibroid or fatty degeneration. In all the microscopic sections hypertrophy of the arterial coats in the foetal blood-vessels was noted, and those nearest the maternal surface were absolutely obliterated."

It must be remembered that all women afflicted with syphilis do not present lesions of the disease in the placenta, so that, with all the information at our command, we are not yet able to demonstrate with precision at all times what is, and what is not, a syphilitic placenta. There are, however, several conditions which, when present, are almost pathognomonic of the disease. They may be enumerated here as consisting of great hypertrophy of the placental villi, fibrous and beginning fatty degeneration of these villi, and thick, fibrous proliferation of the decidua layer of the placenta. When these conditions are found existing conjointly, the suspicion of

syphilitic placenta is as near to a certainty as is possible. In the elucidation of this condition, great aid toward diagnosis can be attained by making a rigid examination of the newly born child. It may be extremely emaciated and puny, and may present evidences of snuffles, but these are not constant, and are, even when present, unreliable. There is, however, a peculiar condition associated with the joints that is certainly characteristic. It may be said to be unfailing evidence in syphilitic foetuses. It consists of a pathological band of abnormal tissue situated between the shafts of the bones and the cartilages of their epiphyses. This appears to be in a constant state of irritation, due to a low state of chronic inflammatory action. There is no other condition or disease akin to this, and it may, therefore, be considered peculiar to syphilitic children. Taken in association with the evidences already stated as being found in the placenta, a proper diagnosis of syphilitic placenta can usually be determined.

In parting with the various diseases of the placenta herein enumerated, it may be stated in a broad, general way that the detrimental effect to the child will depend upon the amount of damage that is inflicted upon its tissues. Disease may affect portions of the placenta, but sufficient may yet remain intact to carry on its function. All gradations of this may occur. When the function is but partly carried on to the termination of pregnancy, the child will present all the evidences of progressive starvation. In cases in which the process is acute, and a large surface of the placenta is seriously involved in some morbid condition, the life of the child is soon terminated. At first the movements of the foetus are restless, and sometimes tumultuous, and then it gradually subsides into quiescence and death. By the aid of the stethoscope, the heart beats will be found to have ceased, and then the mother may experience a peculiar heavy feeling in the womb.

Diseases Attributable to the Cord.—The cord consists of two umbilical arteries and a vein. They are held in their relative positions and prevented from kinking by a peculiar gelatinous material, known as Wharton's jelly. The average length of the cord is from eighteen to twenty inches, but it is liable to variations. Occasionally its length is excessive and may measure fifty or sixty inches, and a case is reported in which it attained nine feet. The cord itself is usually attached to the centre of the placenta, although, on rare occasions, it may be inserted in the margin. It is then known as *battledore placenta*. Other anomalies are sometimes found. There may be two cords instead of one, or the cord may split before reaching the placenta. When the cord is of unusual length, it may become twisted about the limbs or neck of the child, so as to interfere with its free circulation. It is not an uncommon occurrence to see the cord twisted around the neck several times. When the jelly of Wharton is normal in amount and evenly distributed little disturbance will follow. Occasionally, however, the cord is so tightly drawn as to impede the circulation and

interfere with the respiration and the nourishment of the foetus. Knots in the cord are sometimes found. They are caused by the foetus passing through open loops of the cord. If at all tight, they may obstruct the circulation and cause the death of the child.

(To be continued.)

THE PREPONDERANCE OF MALE STAMMERERS OVER FEMALES.

BY DAVID GREENE,
NEW YORK.

KUSSMAUL truly remarks about stammering that "the literature of this impediment of speech has reached enormous dimensions." Yet it may be safely asserted that the subject is far from being exhausted. The speech specialist may be thoroughly familiar with all the conclusions that have been recorded by others, still, if he keeps his ears and eyes wide open during his work, he will almost continually make new and interesting discoveries; for the erroneous vocal actions of stammering are so eccentric as to present new features in almost every case. Perhaps some of the readers of the *Journal* will be interested in an account of some of the experience which I have had of late years along these lines.

Table I shows the results of an examination of 256 adult stammerers, 229 of whom were males and 27 females:

TABLE I.

	Males.	Females.
Number of cases of stammering caused by faulty inspiration.....	139	3
By faulty expiration:		
(a) Mismanagement of the voice..	25	20
(b) Defective articulation.	8	—
(c) Mismanagement of the voice and defective articulation... ..	57	4
Total.	229	27

In this table the classification of the various forms of stammering has been made to depend upon the particular region of the vocal tract in which the faulty action causing this speech defect takes place. This seems to be the most rational classification that can be devised.

Of the total number of cases examined, 229, or 89.45 per cent., were males, and 27, or 10.54 per cent., were females. These results very nearly agree with those found by Colombat, Gutzman, Coen, and other European specialists, all of whom state that "in round numbers there are, among 100 stammerers, 90 men and 10 women."

It has long been a mooted problem why there should be so many more male stammerers than females. Various theories have been advanced to explain this disparity in numbers. Some of these theories are complimentary to the fair sex, but others are not. Some investigators

have suggested that the different mode of breathing of females may be the cause of their comparative immunity from this blemish of utterance, but no definite conclusion on this point seems to have been arrived at

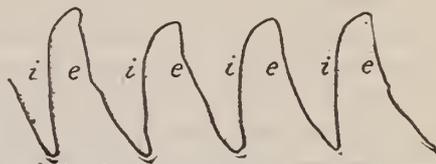

FIG. 1.—Ordinary, quiet breathing; i, inspiration; e, expiration.

by anybody. In my humble opinion, Table I throws considerable light on this subject, for it shows that faulty inspiration was the cause of stammering in 139 males, or 60.96 per cent., and only in 3 females, or 11.11

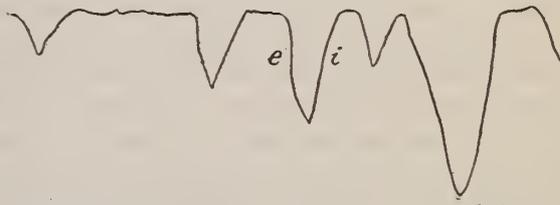

FIG. 2.—Irregular breathing caused by mental agitation while being asked a question.

per cent., of the number of cases examined. The worst case of them all was that of a young man twenty-three years old, of fine athletic build. When attempting to speak, he would first become somewhat agitated and

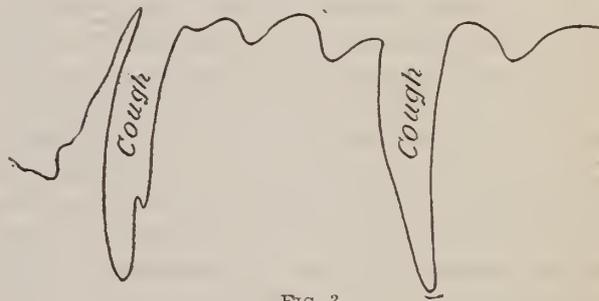

FIG. 3.

move his head and the upper part of his body from side to side, then he would give from six to ten short, hacking coughs, then he would pause for four or five seconds, and when at last he commenced to speak, the words came

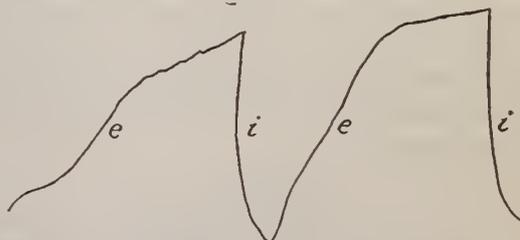

FIG. 4.—Respiration while speaking.

out in a perfectly normal way. The appended tracings (Figs. 1 to 4) show the successive actions of this young man's diaphragm during his attempts at enunciation, as recorded by means of Marey's pneumograph.

By placing your hands on the proper region of the body of a breath stammerer of this class during one of his struggles, you can plainly feel the unnatural spasmodic contractions of the diaphragm and notice an almost entire absence of any rib movement. For the time being, the two mechanisms are out of gear, as it were. When, by great effort, they are brought into gear again, the lower ribs expand, the breathing becomes costo-abdominal, and words are enunciated in a perfectly normal manner. This tendency to misdirected effort in the diaphragm is the most prolific source of stammering among men, but is rarely found among women, as may be seen from my table. It is quite natural that this should be so, for, as is well known, in the male subject ordinary, quiet respiration for vital purposes is effected almost exclusively by the activity of the diaphragm; but, in speaking, a more considerable emptying of the quantity of air in the lungs must take place, and this can only be effected through the combined processes of diaphragmatic and costal breathing. In females, costal breathing is the habitual mode of respiration, hence their lungs are generally well supplied with the quantity of air which is necessary for speaking purposes, and cases of stammering caused by deficient inspiration are very rare among them. This fact sufficiently accounts for the great preponderance of male stammerers over females.

The table of statistics which I have given shows another fact of considerable interest. The number of males in whom stammering was caused, wholly or partly, by mismanagement of the voice is 82, or 35.8 per cent., and the corresponding number of females is 24, or 88.88 per cent., of the total number of cases. Instead of setting the vocal cords into vibratory motions by means of the expiratory current, the stammerers of this class make a futile effort to produce these vibrations by means of the muscles of the larynx, and every time that an attempt is made to pronounce a word beginning with a vowel or a vocalized consonant, a noise is produced which very much resembles the bleating of a sheep. It is perfectly natural that this tendency to throw too much energy into the muscles of the larynx, as a substitute for expiratory force, should be more common among females than among males. Waldenburg, Eichhorst, Biedert, and other German scientists who have examined thousands of cases by means of the pneumotometer give the figures as in Table II, showing that the average respiratory force of females is considerably lower than that of males:

TABLE II.

I.—FORCED RESPIRATION.

	Inspiration.	Expiration.
Men.	100	120
Women.	60	80

II.—ORDINARY, QUIET RESPIRATION.

	Inspiration.	Expiration.
Men.	60	80
Women.	40	50

It is not within the scope of this article to discuss the methods of correcting stammering in general, or breath stammering in particular. However, a few words on this point may not be out of place. The struggle for breath often causes the stammerer to become red and blue in the face, to contort his limbs, etc. Yet this apparently severe type of stammering yields more readily to proper training than voice stammering, which the uninitiated are apt to consider a mild form of this disorder of speech. The student can see and feel the movements of his ribs and easily learn to control them. Gymnastic drill for the development of the purely costal type of breathing, such, for instance, as is described by Campbell in his recent work on *Respiratory Exercises in the Treatment of Disease*, will often cure the severest form of stammering from faulty inspiration in a short time. But the organ of voice is not so easily brought under control. Hence the stammering of females, which in most cases manifests itself in spasms of the vocal cords, usually proves very obstinate.

1122 BROADWAY.

THE MANAGEMENT OF GONORRHŒA.*

BY BOLESŁAW LAPOWSKI, M. D.,

NEW YORK.

ASSUMING that the patient is seen by the physician within twenty-four hours of his noticing the discharge of his first gonorrhœa, let us follow up his treatment with some explanatory bacteriological and anatomical additions. The patient appears within twenty-four hours of noticing his discharge, which bacteriologically and anatomically means that the gonococcus, which invaded the mucous membrane three or four days before, during the act of cohabitation, has passed over the tightly arranged squamous epithelium of the fossa navicularis, penetrated the double layer of the columnar epithelium down to the submucous layer, invaded *en masse* the lumen and epithelium of Morgagni's pockets, some of which reach twenty-seven millimetres in length, entered the lumen of Littre's glands, which are concealed in the tissue of the corpora cavernosa, and, disturbing the normal function of the tissue, produced an inflammatory discharge, for which the patient comes to the physician. He copes with this condition by first having the patient pass water, and then irrigating the urethra with potassium permanganate—two mechanical procedures by which he removes from the surface of the mucous membrane and from between the folds all that he can wash off. He does not by irrigations with potassium permanganate render the soil of the urethra inappropriate for the growth of the gonococcus, as the serous secretion of the mucous membrane which follows the irrigation is one of the best media for the growth of the gonococcus. Then he applies protargol to kill the gonococci remaining upon the sur-

*Read in a discussion in the New York Academy of Medicine, March 21, 1901.

face, in the glands, and in the deeper tissue. While he may destroy the gonococci that are reached by the protargol upon the surface of the superficial layer of epithelium, the gonococci in the deeper tissues are not reached, and consequently not destroyed, as protargol does not penetrate so deeply as to the tissue in which the gonococci are lodged.

The idea that protargol reaches the deep tissues is neither based upon reliable laboratory experimentation nor supported by clinical facts. The best proof of its failure to reach the gonococci is that the gonococci supposed to be killed reappear if the application of protargol is discontinued for several days. They even reappear after from two to four months of the use of protargol. The deep gonococci do not reach the surface in numbers, as the emigration of pus cells—the carriers, as they have been called, of the gonococci from the deep tissues to the surface—is checked by the treatment. But when, in spite of these objections, one professes to cure the gonorrhœa, to reach and kill the gonococcus by this method, we must be permitted to ask for satisfactory proofs. But we shall come later to this point.

Not only can an acute attack of gonorrhœa be cured, but changes in the tissues can be prevented from developing and the gonococci entirely removed from the given organ, provided (1) that the gonococcus is reached by our remedies and quickly annihilated before it has time to provoke tissue changes, and (2) that a *complete physical and partial physiological rest* is given to the organ affected.

Look at gonorrhœa of the conjunctiva. Neither in adults nor in children is there a chronic form of conjunctival gonorrhœa; the conjunctiva is restored to its normal condition, it heals up completely, because both requirements are here fulfilled. We fail to obtain the same results in acute gonorrhœa of the urethra because neither are its deep tissues accessible to us, nor can we give to the organ a partial physiological rest; each micturition, each emission, each erection produces a hyperæmia of the mucous membrane which brings out an exudation of pus cells, raises the epithelium, and opens a door for complications and the development of chronic gonorrhœa.

The most obstinate symptom in chronic gonorrhœa is the presence of the pus cells and threads in the urine. After moving the gonococcus from the deep tissues to the surface by means so admirably presented to us by Dr. Van der Poel, and after removing or destroying it on the surface by medicinal irrigations, some physicians pronounce the patient cured if after repeated examinations of the persistent threads and pus cells they do not find gonococci in them.

Other physicians maintain that the purulent discharge must be stopped or changed into a mucous discharge, for the presence of pus cells evokes always a suspicion of the presence of the gonococcus in some deep tissues, and that by more telling means, such as dilatation, or even forcible dilatation if necessary, the gono-

coccus can be brought into view. And in some cases they have succeeded in bringing the gonococcus to the surface by forcible dilatation when other methods had failed to accomplish it. But this procedure is laden with dangers for the local, and especially for remote, organs. The gonococcus has no motility. It is carried to the distant organs by the circulating blood, producing there severe, and often destructive, changes. I will read to you a list of tissues and organs in which the gonococcus has been found and its identity proved by means of the microscope and positive cultures, and in some cases by the microscope, by positive cultures, and by inoculation into human beings.

Not counting the genito-urinary organs of both sexes, it has been found in the circulating blood in seven cases (one of human inoculation); in the endocardium in seven cases (three of human inoculation, 100 clinical cases reported); in the pericardium in two cases (one of inoculation); in the pleura in two cases; in the knee in seven cases; in tendon synovia in seven cases (one of inoculation); in the perichondrium in one case; in bone marrow in one case (in the humerus); in the peritonæum in five cases; in Douglas's pouch in one case (abscess); in the spleen in one case (pure culture); in intramuscular abscesses in two cases (one after catheterism); in the buccal cavity in two cases; and in a nodule of erythema nodosum in one case.

Let me express here my appreciation of the admirable work done in the Johns Hopkins Hospital by Dr. Thayer, Dr. Blum (the first discoverer of the gonococcus in the blood), Dr. Young, and the late Dr. Lazear, whose observations and contributions have given a new trend to our conception of gonorrhœa. The parts enumerated were attacked during acute, chronic, and latent gonorrhœa, without any provocation in the genital organs, except in one case, in which infective cohabitation took place during menstruation. Moreover, I emphasize here that in many of the cases enumerated the disease was due to the presence of the gonococcus alone, as was shown by all these cases have happened within the last six years.

the obtaining of the gonococcus in pure cultures. And

But the dislodged gonococcus is not always carried away by the blood. It oftener finds its way into a neighboring open duct, and, owing to its disposition to persist and its ability to develop, will reappear in the threads at some future time. Thus the game of hide-and-seek between the physician and the "industrious little beast," as the gonococcus was called by the late Lawson Tait, goes on for years. In the vast majority of cases the physician, failing after repeated microscopical examinations to find the gonococcus in the purulent or mucous threads, pronounces the patient cured. Thus from a negative result he draws a positive conclusion.

Here we come to the main point of the discussion. What proofs does the physician give to support his opinion? It is far from being sufficient evidence when we, from negative microscopical examinations, even with

the use of Gram's method, draw the conclusion of the absence of the gonococcus, for this one out of many other reasons, that the gonococcus may be present in the threads, and Gram's method will not expose it in its classical form, and, owing to the changes of its form, it is usually taken for a diplococcus.

There is a stage in the life of the gonococcus when it is in a condition of involution, especially in chronic gonorrhœa. Such involution gonococci may linger in the tissues for years, and, owing to some favorable change in the tissues, suddenly develop a more active existence. Such involution gonococci are not decolorized by Gram's method, but grow on appropriate culture media into full-sized gonococci. For the benefit of those who express doubts as to the existence of such forms of gonococci, I will say that such a form, first described by Wassermann as found in artificial cultures, has been seen by Ghon and Schlagenhofer in a pocket of the mitral valve of the heart—a natural culture tube—in a woman who had died from endocarditis gonorrhœica. The bacteriological examination of the contents of the valvular pocket gave the gonococcus in pure culture.

Thus, only bacteriological examinations can be regarded as proof of the existence or absence of the gonococcus. I know too well that, even with bacteriological examinations, mistakes are possible, but with them we at least are doing all that it is possible to do in the present state of our knowledge. Especially must we demand a bacteriological examination when the patient seeks our advice as to marrying, which, in many cases, means permission to marry.

If, in advising the present sufferers from gonorrhœa, you will be guided by the foregoing remarks, and, in informing the future candidates for gonorrhœa, advocate the only radical cure for it, namely, not to contract a gonorrhœa, you will not only follow the modern conceptions of the treatment of gonorrhœa, but act in accord with that management of the disease which the future will witness.

Therapeutical Notes.

For Indolent Ulcers of the Cornea.—Dr. McIntosh (*Maritime Medical News*, March) recommends the following ointment:

℞ Yellow oxide of mercury 4 grains;
Atropine sulphate 2 "
Petrolatum 1 ounce.

M.

Potassium Permanganate in Lupus.—M. Hallopeau (*Gazette hebdomadaire de médecine et de chirurgie*, March 21st) recently reported to the French Society of Dermatology and Syphilography the results of his trial of Butte's method. He exhibited four patients showing very favorable results of the treatment, which seemed especially useful in the ulcerating forms; its efficacy appeared less in lupus non exedens.

Either a compress saturated with a one-in-fifty solu-

tion of potassium permanganate, or powdered permanganate itself, is applied daily for a quarter of an hour upon the lupoid spots.

Apocodeine for Constipation.—The *Progrès médical* for March 23d ascribes the following formula to Combe male:

℞ Apocodeine hydrochloride 7½ grains;
Sterilized water 12½ drachms.

M. Two cubic centimetres (about half a drachm) to be injected subcutaneously.

A Tonic in Urinary Troubles.—M. Bazy (*Journal des praticiens*, February 16th) gives the following for mulæ:

℞ Extract of cinchona, from 1½ to 2¼ grains;
Fresh extract of kola nut. ¾ of a grain.

M. For one pill. Six to be taken daily, two at each meal, for twenty days.

Or:

℞ Extract of cinchona, from 1½ to 2¼ grains;
Quinine chlorhydrosulphate. ¾ of a grain.

M. For one pill. Six to be taken daily.

Or:

℞ Extract of cinchona, from 1½ to 2¼ grains;
Powdered rhubarb ¾ of a grain.

M. For one pill. Six daily.

As auxiliaries, caffeine subcutaneously (from 7½ to 15 grains in two or three injections in a day); strychnine, ¼ th of a grain, hypodermically, twice or three times in a day; or camphorated oil, ten-per-cent., 15 drops every three or four hours.

Caffeine is the most diuretic, but is somewhat exciting, and theobromine is preferable where the diuretic action alone is desired.

The Administration of Phosphoric Acid.—Bardet (*Nouveaux remèdes*, January 8th; *Journal des praticiens*, February 9th) recommends the following "lemonade" for persons who find it difficult to take the acid by itself:

℞ Phosphoric acid 420 grains;
Tincture of orange 300 "
Syrup 8 ounces;
Distilled water, enough to make . . . 1 quart.

M.

Twenty-five drachms of this preparation contain 15 grains of the anhydrous acid. Half a claretglassful is to be taken from once to six times a day, or the liquid may be diluted with its own bulk of water and used as the habitual drink.

To avoid the sour taste and astringency of this preparation, Bardet combines the phosphoric acid with albumen according to the following formula:

℞ White of egg, } each 1 ounce;
Phosphoric acid, }
Distilled water, enough to make . . . 12 ounces.

Boil over a water-bath until complete solution occurs; filter, and then add slowly, while constantly stirring, the following mixture:

℞ Tincture of orange 6 ounces;
Syrup 12 "

Complete the quart with distilled water.

A coffeespoonful contains a grain and a half of the anhydrous acid. From ten to fifteen such spoonfuls, added to the usual drink, may be taken in the course of a meal. A hundred parts of the official phosphoric acid, he adds, contain 36.4 of the anhydrous acid.

THE NEW YORK MEDICAL JOURNAL,
62-68 West Broadway.

NEW YORK, SATURDAY, APRIL 13, 1901.

DR. JACOBI'S JUBILEE.

FRIDAY night of last week was memorable in the history of the New York Academy of Medicine. Then was celebrated the fiftieth anniversary of Dr. Abraham Jacobi's graduation in medicine. The real anniversary fell on the day before, April 4th, but a regular meeting of the academy was to be held on that evening, and, although the academy, for whose proud standing and solid prosperity Dr. Jacobi has done so much, would have felt that it was doing itself an honor in postponing its accustomed work and giving up the evening to its beloved ex-president, he himself would not have it so, but insisted on putting off the celebration until the next night. This is what might have been assumed from his rare delicacy, equaled only by his comprehensive hospitality as shown in the wording of the invitation addressed to "the fellows of the New York Academy of Medicine and their and his friends." A goodly number of physicians it was that assembled to greet Dr. Jacobi, and right heartily did they show their gladness for the unabated persistence of his mental and bodily powers.

Dr. Jacobi entertained the company with a paper entitled German Text-books Half a Century Ago; History and Reminiscences. In it he dealt by no means exclusively with text-books; he rather gave a vivid picture of the leading events in medicine during the last fifty years. Mention was made of some matters that he himself regarded as too personal for publication. We all realize, as Dr. Jacobi did, that certain things may properly be said to one's friends, and yet one would prefer not to have them spread before outsiders. But Dr. Jacobi, in his modesty, failed to recognize that in the American medical profession there were no outsiders so far as he was concerned; and it has seemed to us that anything that has helped to shape the career of this remarkable

man or in the least degree tinge his views of things medical is of more than ordinary interest to his professional brethren. Therefore—with Dr. Jacobi's reluctant consent, we admit, but greatly to our readers' delight, we feel sure—we publish in this issue of the *Journal* the entire address.

Few men, if any, have exerted upon the medical profession of the United States a more wholesome influence than Dr. Jacobi's, have done more than he has done to advance medicine or to cherish within the profession a feeling of brotherhood. Not only do we all admire his gifts and his attainments; we love the man himself. The jubilee, following so close upon the *Festschrift*, has but served to mark this feeling; neither the one nor the other was needed to promote or nourish it.

ETHER VERSUS CHLOROFORM.

THIS is indeed a hackneyed subject, but never should its discussion be dropped till the last man of those who, however unconsciously, set convenience above safety has cried *peccavi!* It is not at all strange that in Scotland the preference for chloroform should die hard, for it was in that country that the use of chloroform as an anæsthetic had its origin. It is on that account all the more gratifying to encounter so strong a Plea for the More General Use of Ether as an Anæsthetic in General Surgery as is contributed to the March number of the *Scottish Medical and Surgical Journal* by Thomas D. Luke, M. B., anæsthetist to the Deaconess Hospital and to the Dental Hospital, Edinburgh. "Let it be granted," says Mr. Luke, "that a major operation is about to be performed, and ask any member of the medical profession—north of the Tweed—be he hospital surgeon or country practitioner, what he would use to produce anæsthesia, and it is by no means putting it too strongly to say that ninety-five out of one hundred would reply—'chloroform!'" This, he goes on to say, is largely due, not to any known inferiority in ether as a producer of anæsthesia, but to the fact that in all the large Scottish schools the students see chloroform given as a matter of routine, while the use of ether is not taught, and its great advantages in many cases are not demonstrated. This state of things he laments quite properly and energetically, and he proves once more the overwhelming superiority of ether from the point of view of safety; indeed, he goes far toward showing that it is no less convenient than chloroform. Ether, he says, given as it should be, preceded by the administration of a small amount of nitrous

oxide, is not slow of operation; it is more rapid than chloroform, the patient being fit for operation in from three minutes to three and a half on an average, and, given in this manner, it is by no means unpleasant, as from personal experience he can testify.

The "pet bugbear" of bronchitis as the result of the administration of ether "is largely a relic of former days and imperfect methods," says Mr. Luke. "The cloth was laid across the patient's face and drenched with ether, almost suffocating him with the pungent vapor, and making him cough and gasp until he finally went 'under'; and then the saturating process was kept up, the patient breathing an Arctic atmosphere, rendered so in the vicinity of his mouth, etc., by the rapid evaporation of the anæsthetic; and that bronchitis was not more common is to be wondered at." If ether is skilfully given, he contends, bronchitis as an after-effect is almost unknown. On this point he quotes Mr. Teale, of Leeds, as saying: "During twenty years' experience of ether I have met only one case of bronchitis following its administration." We must add, nevertheless, that the use of ether, however skilfully managed, does occasionally give rise to a most distressing laryngeal hyperæsthesia that lasts for days; but this is an exceedingly rare occurrence.

We must all admit, as Mr. Luke does, that the vapor of ether is inflammable, but, except, as he says, when the actual cautery is being used near the patient's head or a light is brought too close to it, the danger of ignition is no real objection to the use of ether. "Ether is more difficult to administer," Mr. Luke concedes, "but," he pithily remarks, "at the same time it is well to remember that *it is more difficult to poison the patient with it.*" He ventures to assert, and in this he is quite right, that after a very few lessons a person of ordinary intelligence "is in a position to give ether with greater safety as regards the public than after a similar experience in the use of chloroform." Mr. Luke next combats the dictum that "the after-sickness of ether is more severe than that of chloroform." From his own experience he denies this statement most emphatically, declaring that severe nausea and vomiting are much less common after ether than after chloroform. The vomiting due to ether, he says, usually comes on almost immediately on the withdrawal of the anæsthetic, while the patient is being taken back to bed, and in the great majority of cases it passes off before consciousness is regained. On the other hand, he maintains, in about thirty-five per cent. of chloroform cases the patients are troubled with vomiting "not of a

transient nature, but often of a severe and exhausting kind, persisting in some cases for two or three days, and often associated with great pallor and pulse failure—a condition we do not see after ether." "Snow," he adds, "even recorded a death from severe vomiting following on chloroform administration."

There is one of the alleged dangers of ether to which Mr. Luke does not allude, that of its irritating effect on the kidneys. The dangers of chloroform, say its advocates, are immediate, while those of ether are remote—in allusion to the contention that ether exerts a deleterious action on diseased kidneys. This, in our opinion, is little better than an assumption; we have seen nothing to satisfy us to the contrary. We look upon the exclusive use of chloroform in major operations as highly dangerous; at the same time we would tolerate its employment for the production of *anesthésie à la reine*.

A SINGULARLY TOLERANT UTERUS.

Man könne an der Geburt die Allmacht Gottes erkennen wrote a German obstetrician many years ago, and, in spite of the frequency with which trifling occurrences bring pregnancy to an untimely end, his pious observation is almost as applicable to gestation as to parturition. A striking example of extraordinary tolerance on the part of the gravid uterus is related by Dr. A. Olivier in the January number of the *Annales de la Polyclinique de Paris*. A woman was married on the 21st of August, 1899. She expected to be unwell at some time between the 12th and the 15th of September. There was no appearance of the catamenial flow until the 16th of that month, however, and it lasted for only a few hours. It was soon followed by the early symptoms of pregnancy, and on the 28th of November Dr. Olivier was summoned to her bedside. He found her apparently threatened with an abortion. She had had some slight colicky pains the day before, and for three hours she had been losing blood. The uterus was as large as a medium-sized orange, the cervix softened, directed backward, and closed. A little blood was still escaping. Absolute rest in bed, laudanum, and viburnum were prescribed; in three days the flow had ceased, and the threatening abortion seemed to have been averted.

At this stage of the case the woman's mother asked her own physician to see the patient. That practitioner came to the conclusion that an incomplete abortion had taken place, and declared that curetting was absolutely necessary, and that without delay, if infection was to be

avoided. To this, however, Dr. Olivier, strong in his conviction that there had been no abortion, since no clot or any solid body had been expelled, refused his assent. The woman's husband was, nevertheless, so wrought up that he insisted on Dr. Olivier's seeing his wife in consultation with a hospital surgeon. The doctor consented, remarking, however, that he thought an obstetrician more "indicated." The consultation took place on the following day, and it was then learned that on the day before the patient had had some rather sharp pains in the right side, lasting for a few minutes, that she had expelled a thick, blackish liquid, and that her abdomen had become very much enlarged. A mass was found to occupy the right side of the abdomen, reaching to a little above the umbilicus, the cervix being situated very high and to the left. The patient was very pale, but so she had been since an early period in her pregnancy. She had a good pulse, and it was of normal frequency. The surgeon made a diagnosis of extra-uterine gestation with subperitoneal rupture of the sac, and announced that an immediate operation was required to prevent a fresh rupture that might be fatal. Dr. Olivier felt that the surgeon was wrong, but he deferred to his high authority, and an operation was appointed for the next day. When the abdomen was opened, it was found that the tumor was nothing else than the uterus, probably filled with clots. The surgeon closed the abdominal incision and urged the attending physician to curette the uterus. This Dr. Olivier, who must by this time have felt like praying to be delivered from consultants, utterly refused to do, and the sequel abundantly justified his reliance on common sense.

The patient speedily recovered from the operation, and the uterus diminished in size. Thereafter the pregnancy went on without disturbance, and on the 11th of May, in the dead of night, the patient was awakened by an inundation; the bag of waters had broken, pains set in promptly, and in four hours a well-developed and living child was born. Gentle expression soon brought the placenta away. It consisted of two masses connected by a slender isthmus. The foetal envelopes had ruptured at a distance of about two inches from the edge of the placenta. On their outer surface, over a space about four inches square, there was a layer of old organized clots of the color of *café au lait*, the remains of the blood that had been poured out at the time of the hospital surgeon's diagnosis of a ruptured ectopic gestation sac. That the pregnancy should have gone on nearly to full term after abdominal section is not much to be wondered at, for

many a similar occurrence is on record, but it is remarkable, as M. Olivier points out, that the uterus of a primipara less than three months gone in pregnancy should undergo the enormous distention caused by the hæmorrhage and yet not expel its contents prematurely. The case emphasizes the view that abortion is seldom inevitable, provided there has been no artificial interference.

WHERE THE CRIME OF THE CHRISTIAN SCIENTIST LIES.

THE disingenuous methods adopted by the supporters of Christian Science were well displayed in a stormy discussion which, according to press reports, took place at a recent meeting of the Society for Medical Jurisprudence. One of the speakers pleading for "toleration" is reported there to have said: "Why, the very things they do are done in every Protestant and Catholic church in the country. Go into any of them, and if one of their prominent members happens to be sick, you will hear them praying for his recovery without any regard to whether he has a doctor or not." But when has any objection ever been made to Christian Scientists, or any one else, not only praying for the recovery of the sick, but even bringing to bear the influence of the strongest possible suggestion toward it? The Christian Scientists do *not* pray "without any regard to whether he has a doctor or not," or, as we should prefer to express it, without regard to whether all known material or mechanical aids are used, or not. There could not be the remotest objection to their supplementing material and mechanical therapeutic efforts with any mental process they chose to employ. Every Christian, of whatever denomination, daily utters, or should utter, the simple petition, "Give us this day our daily bread," and that, or a similar tribute of reliance upon the Omnipotent One, is used by many who do not profess to be Christians; but none of them considers that that fact justifies him in sitting down idly and folding his hands, without making an effort to attain that for which he prays. Would any Christian Scientist exonerate the guardian of a child, should the child die of starvation because its guardian withheld all food, on the ground that matter was nothing and only Divine Mind fulfilled the processes of nutrition and caused the progress of the being in growth and health? Suppose a Christian Scientist's own child were playing in front of a fast-speeding car, and a man standing by did not even stretch out a hand to drag it away, not believing, forsooth, in material measures, but relying solely on the strength of Divine Mind. We should like to hear the Christian Scientist's opinion of that inhuman creature. No. It is not what the Christian Scientist does, it is what he refuses to do, that constitutes his crime against religion, society, the community, and the individual.

A CHRISTIAN SCIENCE MIRACLE.

It is related that Charles Lamb and Douglas Jerrold were once discussing the extent to which animals could be domesticated, when Lamb in support of his argument told the story of a tame oyster which used to follow him up and down stairs. To this Jerrold retorted that the oyster had one advantage at least over Lamb. "What is that?" asked Lamb. "It knows when to shut its mouth," tartly responded Jerrold. At the recent dedication of a new Christian Science meeting house it was officially stated that a granite corner-stone had been duly carved with an inscription wrongly given under a misapprehension, and that the day before it was to be laid the mistake was discovered too late to admit of alteration. The omnipotent witchery of Christian Science methods, the mental concentration and focussing of "truth" upon this "error of mortal mind" enshrined in granite, was brought to bear by the undaunted devotees, when, lo! upon uncovering the block it was found that the erroneous earving had disappeared and an unexceptionable inscription had taken its place. We are curious to know whether the engraver was guilty of a fortunate disregard of his instructions, or the error therein was discovered and corrected in time, but secretly for the sake of subsequent "effect," or the narrator—. But, no. Let us rest content with recommending the moral of the Lamb-Jerrold story to the notice of the votaries of Christian Science.

A NEW PHILADELPHIA WEEKLY.

WE have received the first number, dated April 6th, of a new weekly journal entitled *American Medicine*, published in Philadelphia and edited by Dr. George M. Gould. In its appearance and arrangement of contents it closely resembles the *Philadelphia Medical Journal*. The first issue contains forty-eight double-columned pages of reading matter, each page of the same width as our own and a little shorter.

POISONING WITH STAR-ANISE.

THE fruit of the star-anise, *Illicium anisatum*, although official in the United States as *illicium* and in Great Britain as *anisi stellati fructus*, is, we imagine, little used in either of the great English-speaking countries. On the continent of Europe, however, it seems to be oftener employed, and occasionally its poisonous effects have been observed, as in a case reported by Etienne, of Nancy (cited in the *Klinisch-therapeutische Wochenschrift* for March 17th). A woman forty years old, suffering with flatulence, infused about an ounce of star-anise in a glass of water, allowing the infusion to stand on the stove for twenty-four hours, so that by evaporation it was reduced to a few teaspoonfuls. She drank the whole of it, and in two hours she was attacked with vertigo, severe vomiting, and collapse. She was revived by the use of alcoholics and injections of ether and caffeine, and the next day she was in her usual health.

News Items.

Society Meetings for the Coming Week:

MONDAY, April 15th: New York Academy of Medicine (Section in Ophthalmology and Otolaryngology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, April 16th: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, April 17th: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

THURSDAY, April 18th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, April 19th: New York Academy of Medicine (Section in Orthopædic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynæcological Society.

Infectious Diseases in New York:

We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending April 6, 1901:

DISEASES.	Week end'g Mar. 30		Week end'g Apr. 6	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever.....	25	11	29	11
Scarlet Fever.....	709	38	725	44
Cerebro-spinal meningitis.	0	0	0	3
Measles.....	313	8	289	6
Diphtheria and croup.....	268	47	266	48
Small-pox.....	41	10	42	8
Tuberculosis.....	286	195	269	148

Marine-Hospital Service:

Official List of the Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending April 4, 1901:

BILLINGS, W. C., Assistant Surgeon. To proceed to San Francisco for special temporary duty.
 CARMICHAEL, D. A., Surgeon. Relieved from duty at Honolulu, H. I., and directed to proceed to San Francisco.
 CURRIE, D. H., Assistant Surgeon. To proceed to San Francisco for special temporary duty.
 HASTINGS, HILL, Assistant Surgeon. To proceed to Bakersfield, California, for special temporary duty.
 PECKHAM, C. T., Surgeon. Granted twenty days' additional leave of absence on account of sickness.
 PRIMROSE, R. S., Acting Assistant Surgeon. Granted leave of absence for five days from March 30th.
 WHITE, M. J., Assistant Surgeon. To report to Surgeon J. H. WHITE for duty.

Naval Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for Two Weeks ending April 6, 1901:

BLACKWELL, E. M., Assistant Surgeon. Detached from the *Abarenda* and ordered home to await orders.
 BOGERT, E. S., Medical Director, retired. Ordered to the Boston Navy Yard.
 DAVIS, E., Assistant Surgeon. Granted leave of absence for three months on account of sickness.
 MARCOUR, R. C., Assistant Surgeon. Detached from the Havana Naval Station and ordered to the *Abarenda*.
 PECK, A. E., Assistant Surgeon. Appointed Assistant Surgeon from March 24, 1901.
 PIORKRELL, G., Surgeon. Granted leave of absence for three months on account of sickness.
 SCOFIELD, W. K., Medical Director. To be placed on the retired list, April 28, 1901.

STOKES, C. F., Surgeon. Detached from the *New Orleans* and ordered to the *Solace* upon her arrival at the Asiatic Station.

WINSLOW, G. F., Medical Director. Detached from the Boston Navy Yard and ordered home.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army from March 30 to April 6, 1901:

BAILEY, GUY G., Captain and Assistant Surgeon, will report for transportation to Manila.

FISHER, HENRY C., Major and Surgeon, is relieved from duty in the Division of the Philippines, and will proceed to Jackson Barracks, Louisiana, to relieve AARON H. APPEL, Major and Surgeon, who will proceed to San Francisco for transportation to Manila.

IVES, FRANCIS J., Major and Surgeon, will proceed to Fort Sheridan, Illinois, to relieve GEORGE W. ADAIR, Major and Surgeon, who will comply with the requirements of so much of Par. 17, S. O. 38, February 14, 1901, H. Q. A., as relates to him.

MOSELEY, EDWARD B., Major and Surgeon, will report in person to the commanding general, Department of the Colorado, for duty as chief surgeon of that department, to relieve HENRY LIPPINCOTT, Lieutenant-Colonel and Deputy Surgeon-General, who will proceed to Governor's Island, New York, for duty as chief surgeon of that department.

WHEATE, JUSTUS M., Captain and Assistant Surgeon, will, upon the expiration of the leave granted him, proceed to San Francisco for transportation to Manila.

The Grave of Hippocrates is said to have been discovered during some recent excavations at Larissa, in Thessaly.

Erratum.—In last week's issue, in an abstract of an article entitled *Creosote in Pneumonia: A Résumé* (page 603), for "creosote" substitute *creosote carbonate*.

Dr. F. C. Curtis Reappointed New York State Medical Expert.—Dr. F. C. Curtis, of Albany, N. Y., has been reappointed medical expert of the New York State Health Department by Commissioner Lewis.

A Physician Killed by an Insane Man.—Dr. Johnson, a physician in the State Hospital for the Insane at Danville, Montour county, Pa., was stabbed to death on April 3d by an insane Italian patient.

Municipal Physicians Go on Strike in Germany.—According to a Berlin cable, at Leipsic one hundred and fifty-five municipal physicians have gone on strike for higher pay and more considerate treatment.

A Physician Helped to Capture Aguinaldo.—Dr. W. Parsons Read, of Philadelphia, formerly an assistant professor at the Jefferson Medical College, participated in the capture of Aguinaldo by General Funston.

A Physician Attacked by His Patient.—Dr. G. T. Applegate, of New Brunswick, N. J., was severely handled recently by Charles Johnson, a patient, whom he was treating for dementia resulting from insomnia. Before help arrived the doctor was choked almost into insensibility.

Changes of Address.—Dr. Thomas H. Allen, to The Glenmore, corner of Fifty-fifth Street and Seventh Avenue, New York; Dr. Arthur G. Bennett, to No. 26 Allen Street, Buffalo; Dr. Louis Haupt, to No. 232 East Nineteenth Street, New York; Dr. Alfred W. Herzog, to No. 54 East Thirtieth Street.

Medical Director Scofield Appointed a Rear Admiral.—Medical Director Walter K. Scofield, of Philadelphia, goes on the United States navy retired list on April 28th, retaining the title of medical director, but with the rank of rear admiral added. The retirement of Director Scofield comes after almost forty years of continuous service.

Lectures at the New York Botanical Garden.—The regular spring series of lectures at the New York Botanical Garden will be delivered in the lecture hall of the museum building of the garden on Saturday afternoons at 4:30 o'clock. The course began on April 6th, and closes on June 29th. Among the lecturers is Dr. H. H. Rusby, of the University medical faculty.

Dr. Gaylord to Lecture before the Johns Hopkins Medical Society.—Dr. H. R. Gaylord, of Buffalo, N. Y., will lecture on April 15th before the Johns Hopkins Medical Society, at Baltimore, Md. Dr. Gaylord claims to have discovered the cancer germ. He has had charge of the cancer laboratory in Buffalo since its inception, and has been experimenting on the cancer germ for three years.

A New York Physician's Gift to the Botanical Garden.—Dr. C. R. Allen, of New York city, has presented to the New York Botanical Garden a valuable collection of stoneworts. Dr. Allen is vice-president of the Torrey Botanical Club, and it took him many years of hard work and thousands of dollars to gather the specimens. It is probably the most complete collection in existence.

Dr. S. Edgar Mortimore, of No. 241 West One Hundred and Twenty-second Street, New York city, died at the Church Hospital, Orlando, Fla., on March 21st, of empyema. Dr. Mortimore was born in New York city in 1850, and was a practising physician in Harlem for thirty years. He was a past master of Ivanhoe Lodge, No. 610, F. and A. M., and member of several medical societies. He is survived by a widow, an infant son, and his brother, Dr. Fairfield Mortimore, of this city.

A Proposed Hospital for the Insane in New York City.—Among the bills introduced at Albany lately was one establishing a hospital in New York city for the reception of a limited number of alleged insane and insane persons where skilled observation is necessary in making required pathological and psychopathic research and examination. Admission is to be regulated by the commission, who shall appoint a superintendent having the qualifications of a State hospital superintendent.

The Examination for Medical Licenses.—A bill has been prepared for introduction in the legislature of New York State providing that the regents of the University of the State of New York may, in their discretion, divide the examinations required for a license to practise medicine, permitting a candidate to take the examinations in anatomy, physiology, hygiene, and chemistry at the end of two years' study, instead of requiring, as by the present law, the examinations in these subjects to be taken with the others at the end of the four years' course.

Proposed Legislation to Regulate the Practice of Hypnotism.—The New York Senate committee on public health has reported a substitute for the bill of Senator McCabe to regulate the practice and teaching of

hypnotism, mesmerism, suggestive therapeutics, and other kindred practices. The substitute relates only to hypnotism and mesmerism, and provides that any person who practises these who is not a duly licensed physician or graduate from an educational institution for the teaching of such practice, duly licensed by the regents of the State, shall be deemed guilty of a misdemeanor.

The Lack of Quarantine Facilities at Central and South American Ports.—The danger menacing travelers to Central and South American ports, through lack of quarantine facilities in those countries, has been brought under the notice of the Marine-Hospital Service at Washington by P. M. De Leon, United States consul-general to Ecuador. The consul-general incloses a letter from Archer Harman, manager of an Ecuador railroad enterprise, who tells how the steamer *Chile*, with yellow fever aboard, was turned from port after port for fully a month, while the ravages of the disease continued. There were several deaths.

A New York Temple of Science.—Plans have been announced by the council of the Scientific Alliance of New York for a Temple of Science to cost half a million dollars. For the last ten years the Scientific Alliance has been considering the subject of the erection of a building which should house the various scientific societies composing the alliance. These are the New York Academy of Sciences (the oldest scientific society in New York), the Torrey Botanical Club, the New York Microscopical Society, the Linnaean Society of New York, the New York Mineralogical Club, the New York Section of the American Chemical Society, and the New York Entomological Society.

A Portrait of Dr. Keen Presented to the Jefferson Medical College.—The students of the Jefferson Medical College, at Philadelphia, presented to the college, on April 4th, an oil painting of Professor W. W. Keen at the hospital amphitheatre. The presentation address was made by Professor J. Chalmers Da Costa. William Potter, president of the board of directors, accepted the gift. Dr. Keen has been professor of surgery at the Jefferson College for twenty-one years. He is to leave for a tour of the world, and is not expected to return for two years. The students, to show their respect, had his portrait painted by Professor Chase, instructor of painting at the Academy of the Fine Arts.

Doctors to Investigate New York City's Vice Conditions.—Seven members of the New York County Medical Society have been appointed a committee to investigate the evils of prostitution in the tenement-houses from a physician's point of view. The committee consists of Dr. P. A. Morrow, Dr. S. A. Knopf, Dr. H. D. Chapin, Dr. C. W. Allen, Dr. L. D. Buckley, Dr. Ludwig Weiss, and, ex-officio, Dr. George B. Fowler, president of the society. Dr. Morrow will act as chairman. After its work is under way, it will communicate with the Committee of Fifteen, but its investigation will be wholly along lines which concern the physician as a practitioner.

A Summer Medical Course at the University of Michigan.—One of the most important moves of recent years in the University of Michigan medical department, at Ann Arbor, Mich., is under discussion by the faculty. The plan is to petition the regents for a summer session of the medical school. The innovation will be a radical

one. A special set of professors will be drawn up and presented to the board for approval, and if the move goes through they will take charge of the students' summer work. A number of needy students who find vacation so much time lost will be enabled to thus finish their courses with greater dispatch. A large amount of research work in the laboratories is contemplated.

The Use of Preservatives in Milk.—An attempt is being made at Albany to have the various cases brought to test the constitutionality of the provision of last year's law prohibiting the use of preservatives in milk suspended until the court of appeals decides the appeal in the suit against John S. Bieseker, of New York city. The Bieseker case is one of much interest to the New York County Medical Society, which last fall took up the question. The leading milk dealers of New York city were called into conference with the physicians. They all testified to the use of preservatives by the smaller dealers. Some of the preservatives were chemically analyzed and pronounced injurious. If the court of appeals sustains the decision of the appellate division in the Bieseker case, there probably cannot be new legislation to guard against the preservative evil until next year.

The Inebriates' Home of New York City.—A bill was introduced into the New York Senate on April 5th incorporating the Inebriates' Home of New York city. Dr. William T. Jenkins, A. Campbell White, George R. Bidwell, Delancy Carter, Isaac H. Love, and Frank J. Cuthbert are named as trustees. The home is to be established under the membership corporations law. It is to have the power to receive and retain inebriates under rules provided by the State Board of Charities. Committing magistrates are authorized to commit habitual drunkards to the home for terms varying from six months to a year, according to previous condition and reputation. New York city is to provide for the maintenance of the home. The avowed purpose of the proposed institution is to treat the indigent poor for alcoholism, instead of sending them to prison.

Examinations for Acting Assistant Surgeons in the Marine-Hospital Service.—The United States Civil Service Commission announces that on May 7, 1901, an examination will be held in any city in the United States where postal free delivery has been established for the position of acting assistant surgeon in the Marine-Hospital Service. The examination will consist of the subjects mentioned below, which will be weighted as follows:

Subjects.	Weights.
1. Letter writing.	5
2. Anatomy and physiology.	15
3. Surgery and surgical pathology.	20
4. Chemistry, materia medica, and therapeutics.	10
5. Bacteriology and hygiene.	10
6. Theory and practice of medicine and general pathology.	25
7. Obstetrics and gynecology.	15
Total.	100

The age limit is twenty years or over. From the eligibles resulting from this examination it is expected that certification will be made to the position of acting assistant surgeon in the Marine-Hospital Service, at Portland, Maine, at a salary of \$600 per annum, and to other similar vacancies as they shall occur. This examination is open to all citizens of the United States who comply with the requirements. All such persons are invited to

apply, and applicants will be examined, graded, and certified with entire impartiality and wholly without regard to any consideration save their ability as shown by the grade attained in the examination. Preference may be given to eligibles who are residents of the district in which the vacancy exists. Persons who desire to compete should at once apply to the United States Civil Service Commission, Washington, D. C., for application forms 304 and 375, which should be properly executed and promptly forwarded to the commission.

The Rudolf Virchow Fund.—On October 13, 1901, Dr. Rudolf Virchow will be eighty years old. When he completed his seventieth year a fund was started in his honor to enable the great master to facilitate scientific research by establishing scholarships, and by encouraging special medical and biological studies. Contributions to that Rudolf Virchow fund were furnished by those in all countries interested in progressive medicine, as a homage to the man whose name is always certain to arouse admiration and enthusiasm. In Berlin a large committee, comprising, amongst others, Dr. A. Bastian, Dr. v. Coler, Dr. A. Entenburger, Dr. B. Fraenkel, Dr. O. Israel, Dr. Fr. Koenig, Dr. C. Posner, and Dr. W. Waldeyer, has been formed and has issued a call for contributions, which are to be added to the original Rudolf Virchow fund, so as to increase its efficiency. The committee expresses the opinion that in no better way, and in none more agreeable to the great leader of modern medicine, can his eightieth birthday be celebrated, and asks for the sympathy and cooperation of all engaged in the study and practice of scientific medicine all over the globe.

A subcommittee for the purpose of making the medical profession in America acquainted with the intentions of the Berlin committee has been formed. This committee is composed of Dr. Charles A. L. Reed, president of the American Medical Association; Dr. Henry P. Bowditch, president of the Congress of American Physicians and Surgeons; Dr. William K. Welch, Johns Hopkins University; Dr. Robert F. Weir, president of the New York Academy of Medicine; and Dr. A. Jacobi, 110 West Thirty-fourth Street, New York, secretary. The members of this committee urge their colleagues to participate in honoring the very man who has done more, these fifty years, than any other to make medicine a science and international. Subscriptions should be sent to the secretary, Dr. A. Jacobi, who will receipt therefor.

The Minnesota Marriage Bill requiring a physical and mental examination of all candidates for matrimony, to which we referred in our issue for March 30th, has now passed both houses of the legislature.

The Anti-alcohol Congress which was held recently at Vienna has, according to the press reports, proven quite a turbulent body, the members being divided on the question of total abstinence as opposed to the moderate use of alcoholic beverages.

The "Smoker" of the New York Hospital Alumni Association.—The next regular smoker of the association of the alumni of the New York Hospital will be held in the new private pavilion of the hospital on Tuesday, April 23d, at 9 p. m.

The Brooklyn Society for Neurology.—The regular meeting of the Brooklyn Society for Neurology was held

on March 28th in the building of the Medical Society of the County of Kings. The programme was an especially interesting one, and included a paper on Tetanus, by Dr. T. C. Craig, and another on Paralytic Dementia and Cerebral Syphilis, by Dr. W. Alfred McCorn.

The Rappahannock Valley Medical Association.—At a meeting of the Rappahannock Valley Medical Association held at Fredericksburg, Va., on March 28th, Dr. S. W. Carmichael was elected president for the ensuing year, and Dr. J. N. Barney secretary and treasurer. A paper on Epidemic Influenza or Grippe was read by Dr. Carmichael and discussed by many of the members present.

Two Philadelphia Hospital Associations to Consolidate.—A petition was filed in a Philadelphia court on March 31st asking for the consolidation of the Mount Sinai Hospital Association and the Franklin Free Dispensary, the new association to be known as the Mount Sinai Hospital Association.

The W. C. Hollopeter Pædiatric Society of the Medicochirurgical College held its annual banquet recently in Philadelphia. Professor Hollopeter was toastmaster, and toasts were responded to, among others, by Professor Seneca Egbert, Dr. H. S. Kinne, and Dr. J. L. Manasses. Among the guests were Professor John V. Shoemaker, Professor James M. Anders, Dr. W. L. Pyle, Dr. W. H. Thomas, and Dr. G. W. Pfomm.

The Organization of a New Medical Society Proposed at Louisville, Ky.—A meeting of prominent physicians was held at Louisville, Ky., on March 20th. The object of the meeting was to consider the organization of a medical society for the purpose of scientific research. About fifteen physicians were present, but nothing definite was decided upon. Another meeting will be held shortly.

The Philadelphia Academy of Surgery.—The annual reception and monthly meeting of the Philadelphia Academy of Surgery was held on April 1st, Dr. De Forrest Willard in the chair. There were seventy-five members present. Dr. John A. Wyeth, of New York, was present by invitation of the academy, and read a paper on Amputation at the Hip Joint for Sarcoma. A discussion on the subject followed between Dr. Coley, of New York; Dr. Bloodgood, of Baltimore; and Dr. Keen, Dr. Deever, and Dr. Flexner.

The County Medical Association Meeting.—At the stated meeting of the County Medical Association held on April 8th at the Academy of Medicine, New York, a paper was read on Food as a Factor in the Causation of Disease, by Dr. Elmer Lee. After the discussion on the subject which followed the reading of the paper, Dr. Lee said: "No man can be sick unless poison enters his system. Nor can one be sick who eats satisfactorily and adequately. I think it is impossible for any one to become afflicted with influenza who is in a state of proper nutrition, or to be stricken with cholera or typhoid fever. Sickness is universal, and there must be a universal cause, in my opinion. That cause is bad eating."

The Annual Report of the J. Hood Wright Memorial Hospital.—The annual report of the J. Hood Wright Memorial Hospital for 1900 says that the number of patients treated in the hospital was the largest of all the

years in its history—1,276 patients in the hospital and 1,278 in the emergency ward. The receipts from all sources were \$32,381.38, and the expenses \$27,588.92. The report says that an understanding with the Department of Charities has been reached, and the hospital is now receiving the official compensation for the treatment of emergency cases. The damage suits the hospital has had to defend are said to have been due to patients leaving the hospital against the advice of the physicians.

Hospital Staff Appointments.—Dr. Florence Hall Watson has been elected assistant superintendent of the Delaware State Hospital at Farnhurst, Del., to succeed Dr. John H. Hammond, who has resigned.—The medical and surgical staff of the county hospital at Denver, Col., for the ensuing year will be the same as last, except that Dr. F. E. Waxham succeeds Dr. Seebass, Dr. C. B. Lyman displaces Dr. Clayton Parkhill, Dr. T. M. Burns succeeds Dr. Bertha Conley, and Dr. Sherman Brown is named instead of Dr. H. E. Warren. Dr. C. K. Fleming retires.

Hospital Buildings and Endowments.—The work of erecting a hospital at Batavia, N. Y., will shortly be begun, as the necessary sum has been subscribed, and the site has been purchased.—An additional story will be added to the two-story brick and stone pavilions for convalescent patients of the Isabella Heimath, at One Hundred and Ninetieth Street and Amsterdam Avenue, New York city. The architects have figured the cost of the work at \$30,000.—An anonymous gift of \$1,000 has been made to the Foundling and Sickness Baby Hospital at Montreal.—A bill has passed the Assembly at Albany to provide for the construction of a building for hospital purposes in the Borough of the Bronx, in Greater New York, at a cost not to exceed \$300,000.—A house for nurses is to be built on property adjoining the Hahnemann Hospital at Philadelphia, donated to the hospital by Mr. and Mrs. George C. Thomas, of that city. The trustees also purpose building a maternity hospital.—Ann E. Taggard, a widow, of East Boston, has bequeathed the greater portion of an estate valued at \$75,000 to the founding of an emergency hospital there.—The will of the late Sophia C. Hale, of Newburyport, Mass., bequeathes \$10,000 to the Anna Jaques Hospital of that city.—The ways and means committee of the New York State Senate has reported favorably, as amended, the bill of Senator Davis appropriating \$100,000 for the construction of a hospital in the Adirondacks for the treatment of consumptives. The amendment strikes out the item of \$20,000 for equipment and furnishing purposes.—The National Sanitarium Association has secured a building site for the Toronto (Ont.) free hospital for advanced consumptive cases. As soon as building plans are completed tenders for the buildings will be called for, the contracts let, and the construction work started with the least possible delay.

Births, Marriages, and Deaths.

Born.

OPDYKE.—In New York, on Saturday, March 9th, to Dr. and Mrs. Ralph Opdyke, a son.

Married.

GARDNER—ROWL.—In Bowling Green, Ohio, on Friday, March 29th, Dr. Andrew J. Gardner, of Grand Rapids, Michigan, and Miss Lonetta M. Rowl.

PfINGST—SCHIMPELER.—In Louisville, Kentucky, on

Wednesday, March 27th, Dr. Adolph O. Pfingst and Mrs. Lola S. Schimpeler.

ST. GEORGE—WEBER.—In New York, on Tuesday, April 2d, Dr. Norman St. George, of Boston, and Miss Mattie G. Weber.

SYLVIUS—VAN MARTER.—In Ogden, Michigan, on Tuesday, April 9th, Dr. Elmer O. Sylvius, of Ashtabula, Ohio, and Miss Minnie I. Van Marter.

TAYLOR—HUSON.—In South Orange, N. J., on Tuesday, April 9th, Dr. Edward Thomson Taylor and Miss Gertrude Crane Huson.

THRASHER—SCHMUCK.—In Cincinnati, on Wednesday, April 3d, Dr. Wade Thrasher and Miss Olive G. Schmuck.

Died.

CALVIN.—In Salem, Ohio, on Friday, March 29th, Dr. James H. Calvin, in the fifty-second year of his age.

CARPENTER.—In Washington, on Tuesday, April 2d, Dr. James A. S. Carpenter, in the seventy-fourth year of his age.

GROVE.—In Philadelphia, on Saturday, April 6th, Dr. John H. Grove, United States Army, in the seventy-sixth year of his age.

GUERNSEY.—In New York, on Tuesday, April 9th, Dr. William N. Guernsey, in the fifty-second year of his age.

HACKER.—In Charleston, S. C., on Sunday, March 31st, Dr. F. Herbert Hacker, in the thirty-fourth year of his age.

HALL.—In Manila, on Tuesday, April 2d, Dr. William R. Hall, United States Army.

HAYWARD.—In Boston, on Saturday, March 30th, Dr. George Hayward, in the eighty-second year of his age.

HILL.—In Danville, Illinois, on Friday, April 5th, Dr. Thomas A. Hill, of New York, in the eighty-fourth year of his age.

HORD.—In Washington, on Monday, April 1st, Dr. William T. Hord, United States Navy, in the seventieth year of his age.

HUNTER.—In West Chester, Pennsylvania, on Thursday, March 28th, Dr. John Powell Hunter, in the twenty-eighth year of his age.

HURDMAN.—In Brandon, Canada, on Sunday, March 31st, Dr. B. S. Hurdman, in the forty-first year of his age.

JOHNSTON.—In Danville, Pennsylvania, on Wednesday, April 5th, Dr. R. Erskine Johnston.

LARSH.—In Baltimore, on Wednesday, April 3d, Dr. James C. Larsh, in the eightieth year of his age.

SPEARMAN.—In Philadelphia, on Monday, April 1st, Dr. Alfred Spruance Spearman, of Milwaukee, in the seventieth year of his age.

SUMMERS.—In Charleston, West Virginia, on Tuesday, April 2d, Dr. Albert Edgar Summers, in the seventy-seventh year of his age.

Obituaries.

WILLIAM JAY YOUMANS, M. D.

IN the death of Dr. Youmans, which occurred at his home, in Mount Vernon, N. Y., on Wednesday, April 10th, the medical profession has lost a member who, while not a practitioner, had cast lustre on the guild by his career in literature and general science. More than that, he had endeared himself to a large number of appreciative men and women by his geniality and his readiness on all occasions to engage in the solution of problems submitted to him. For many years the *Popular Science Monthly*, of which until a few months ago he was the editor, was conducted under the same roof with the *New York Medical Journal*, and consequently we had the best of opportunities of knowing him intimately and of profiting by his advice and that of the gentlemen of his staff on many occasions. There was the height of good feeling and there was an atmosphere of confidence pervading the offices of the two journals, and the men who worked in them grew fond of each other. On us, therefore, falls heavily the news of Dr. Youmans's death at the comparatively early age of sixty-two, in the zenith of his mental powers and while yet his bodily vigor was not perceptibly impaired.

Pith of Current Literature.

Boston Medical and Surgical Journal, April 4, 1901.

Diseases of the Myocardium. By Dr. Henry Jackson.—The author deplors the fact that disease of the myocardium does not receive in our text-books the important consideration it deserves. He recommends that two prominent facts should always be kept in view in the consideration of a case of heart disease. These are: (1) That heart disease does not mean valvular disease, and, (2) that murmurs evidently pathognomonic of regurgitation do not prove the existence of organic disease of the valve curtains. A text-book consideration of the subject indicated in the title follows. In the author's opinion, the most important condition indicative of cardiac weakness is met with when there is a discrepancy between the number of beats of the heart and the pulsation transmitted to the radial artery. This phenomenon is met with in typhoid fever, in diphtheria, and in many cases of advanced heart disease with great dilatation of the cavities. The most important cause of enlargement of the heart, and a cause explanatory of a large proportion of cases classified clinically as "cardiac," "weak heart," "cardiorenal" or "fatty heart," is arteriosclerosis.

The Condition of the Myocardium as Affecting Cardiac Murmurs. By Dr. H. D. Arnold.—Whenever a murmur exists it is of great importance to investigate the condition of the myocardium, as, by so doing, we may find the cause of the murmur to lie in an entirely remediable condition of the cardiac muscle, and spare ourselves the mortification, and our patient the life of worry and dread, that would follow upon a diagnosis of incurable valvular disease. In any event, the cardiac murmurs furnish no more important data upon which to base prognosis, than does the condition of the myocardium.

A Further Note on the Treatment of Epidermoid Cancer. By Dr. Francis H. Williams.—This article refers to treatment by exposure to the radiation from an excited Crookes's tube. The author reports cases. In the beginning, the exposure to the rays usually lasted five minutes, and was given nearly every day for some weeks, but further experience has suggested that so long a period of treatment is unnecessary, a few exposures being sufficient in some cases. As the extremely encouraging results reported have been accomplished in superficial growths, penetrating to a depth of two centimetres at least, the author believes that there is reason to hope that something may be done for patients in whom the disease is more deeply seated.

Report of Cases from the Second Surgical Service of the Children's Hospital, Boston. I. Multiple Plexiform Fibromata; II. Paraplegia Existing from Birth. Laminectomy at the Age of Five and One Half Months; III. A Case of Ununited Fracture of the Femur of a Child in which the Non-union was Due to the Formation of a Cyst at the Ends of the Fragments. By Dr. H. L. Burrell, Dr. R. W. Lovett, and Dr. J. E. Goldthwait.

Journal of the American Medical Association, April 6, 1901.

Chloralose. By Dr. James Tyson.—From his experience, the author asserts that chloralose is a prompt and safe hypnotic, more prompt in its action than any drug except morphine, and efficient in much smaller doses than chloral. Its effects occasionally include involuntary actions, which, while surprising, and even fantastic, in some of their exhibitions, are, nevertheless, harmless.

The maximum dose is five grains in a capsule, which may have to be repeated in not less than an hour.

Post-operative Nervous Phenomena or Artificial Menopause. By Dr. Joseph Price.—The author urges prolonged rest treatment after serious operations. He is satisfied that thrice better results can be obtained by turning the patient over, three or four days after the operation, to a good clinician—one who is interested in diet and systematic rest treatment.

Syphilis as a Non-venereal Disease, with a Plea for the Legal Control of Syphilis. By Dr. L. Duncan Bulkley.—The author believes that the time has come when the dangers of syphilis, and especially the dangers to innocent persons, should be fully and fairly recognized and met. It should be made as criminal to transmit syphilis wittingly as it is to communicate small-pox, scarlatina, or diphtheria, and if only syphilis can be included on the list of contagious diseases which the health boards can control, proper legislation will follow slowly, as the profession and public become more enlightened as to the real nature of syphilis and the real danger of the public from it.

Recent Clinical Observations on Tinea Versicolor. By Dr. Charles Warrenne Allen.

Experience with an Epidemic of Rabies in Buffalo. By Dr. Ernest Wende.—The author describes a number of cases in which the classical symptoms were present. He believes that the question of municipal control for the restriction of the spread of rabies is most important. The presence of a large dog population in a community serves no good purpose; its diminution and restriction is indicated, and should be accomplished. Every city, in dealing with dogs, should be provided with efficient rules, regulations, and ordinances, and should demand their rigid enforcement.

Pure-food Legislation versus Poor Food-legislation. By Dr. Murray Galt Motter.—In the author's opinion, the history of food-legislation shows pretty clearly that the consumer may safely be left to his own instinct and experience to determine what is, or is not, wholesome. What he seeks is simply the truth, and the public weal is best conserved by absolute honesty.

Some Observations in Renal Surgery. By Dr. W. H. Allport.

The Relation of Indicanuria and Oxaluria to Gastro-intestinal Fermentation. By Dr. J. A. Wesener.—The author's conclusions to an interesting paper are that: (1) Traces of oxalates are found normally in the urine, having been taken in with the food; (2) oxalate crystals usually denote gastro-intestinal fermentation; (3) abundance of oxalate crystals does not indicate a high acid percentage, because, in addition, there may be oxalate of lime in the solution; (4) indican is often, but not necessarily, associated with oxalate crystals; (5) hyperacidity on a meat diet contributes to putrefaction, whether due to excess of hydrochloric acids or to acids of fermentation; (6) the symptoms of oxalic acid diathesis associated with indicanuria are not due to the oxalic acid, nor to the indol, but to other products formed in the process of fermentation; and, therefore, the oxaluria and indicanuria are valuable as indicative of a putrefaction, to which the symptoms are to be referred.

Some Additional Observations on the Effects of Injury to the Peripheral Nerves. By Dr. D. S. Fairchild.

An Operation for Cystocele. By Dr. George H. Noble.

Individual Prophylaxis. By Dr. W. A. Evans.

Statement Made before the Committee on Public Health of the New York Assembly, at the Public Hearing on Assembly Bill 759, Regulating and Legalizing the Practice of Osteopathy in the State of New York, and Fixing Penalties for the Violation Thereof. By Jacob Bolin.

Medical News, April 6, 1901.

Advertising in the Profession. By Dr. Frank Lydston.—According to the author, the problem of advertising is one from which we cannot escape, and it is his belief that the injunction "Thou shalt not advertise" was written in a Pharisaical spirit, and that it has been the cloak of more inconsistency and hypocrisy than anything ever written for the guidance of medical men. The most important forms of professional advertising are college advertising, medical writing, social advertising, church advertising, secret society advertising, and "that indefinable something known as newspaper prominence, which is called advertising by the fellow who can't get it, and is considered a laudable enterprise by the fellow who does." In general, the author holds that it is the duty of every man in the profession, not only to himself, but to the profession, to bring himself before the public, as a citizen and a representative of the profession, where it can be done respectably, at every possible opportunity.

Resection of the Cervical Sympathetic. By Dr. Howard J. Williams.—This operation is still too new—only four years old—to demonstrate what ultimate deterioration may result. In the author's case, however, the results have been encouraging, and, in former cases, have remained permanent; and, unless some remote baneful effects should be reported to detract from the value of the operation, sympathectomy will eventually receive a permanently recognized position as a surgical procedure in glaucoma, exophthalmic goitre, and other allied neuropathic diseases.

The Question of Drainage in Appendicitis. By Dr. A. M. Pond.—The peritonæum is capable of disposing of very large quantities of pus under favorable conditions; chief among these conditions is equal distribution over the peritoneal area. In order to do this it becomes necessary to use some agent which shall put pus and pus-forming elements into solution. For this purpose, hot saline solution is very effective and fulfils all the requirements; it can be made sterile and introduced sterile into the peritoneal cavity; it possesses the power of putting pus and pus-forming elements into solution, and being hot, temperature 105° to 108° F., is a most active stimulant to the peritonæum, and its use is unattended by unpleasant sequelæ. Increased hepatic activity and posture are other important elements. Cases in which these ideas were put in practice are reported.

New Methods in Charity, with Better Results and at Less Cost. By Dr. William P. Spratling.—The author's points may be summed up as follows: 1. Prevent insanity, epilepsy, imbecility, idiocy, and feeble-mindedness, as far as possible, by making it impossible for persons so afflicted to marry. 2. Build less expensive structures in which defective and dependent State charges shall live. 3. Maintain at less cost the cases that are chronic and incurable, and maintain at greater cost, to stimulate recovery, those that probably can be cured. 4. Give those that ought to have it an education that they can use.

Medical Record, April 6, 1901.

The Relation of the Public to the Medical Profession. By Dr. D. B. St. John Roosa.—In the author's judgment, the individual, the public at large, and the State governments ought to take a positive interest in medical science. No investment can be more judicious than the most generous treatment of the medical profession. Its wants should be provided for, its demands heeded, and legislation pertaining to the public health should be directed by it alone. When human ingenuity, skill, foresight, and care are so efficiently used that no accidents occur, and infectious or contagious diseases do not prevail, it will be due entirely to the scientific and humane labors of the medical profession.

The Importance of Aseptic Vaccination, with Remarks on Vaccination in General. By Dr. Wilhelm Karl Kubin.—The author suggests that a national law for compulsory vaccination such as exists in Germany, and similar to those adopted in many other countries, should be passed. He also recommends that a knowledge of the importance of vaccination should be taught in the schools, so that when children become adults it will not be so difficult to teach them the importance of revaccination. He also emphasizes the necessity of giving special instruction in vaccination in all medical colleges.

The Field for Ethyl Chloride Narcosis. By Dr. Martin W. Ware.—The author proposes the use of ethyl chloride in minor surgery, for the reason that it is as safe statistically as any of the other anæsthetics, while it induces a very rapid narcosis, and an equally quick awakening, and is void of any after-effects. Indications for its use arise in all minor work in which the exact limits of operative procedures can be predetermined. It is also indicated as a preliminary to narcosis with other agents.

On the Diagnosis and Prognosis of Diabetes Mellitus. By Dr. Henry S. Stark.—The author points out that neither acute nor chronic glycosuria, *per se*, is sufficient to warrant a diagnosis. Polydipsia or polyuria, either or both, accompanied by a general deterioration in health, should accompany the glycosuria. This latter—persistent, transitory, or recurrent—should be determined by several interval analyses of a twenty-four-hours' specimen of urine. He believes Rudisch's test is accurate enough for all purposes required by the physician (one tenth of one per cent.).

From a prognostic standpoint, there are three types. To the mild type belong those cases in which the glucose disappears upon the gradual exclusion of carbohydrates. To the medium type belong those cases in which the glucose disappears only after the complete exclusion of carbohydrates. To the severe type belong those cases in which the glucose does not disappear despite the complete exclusion of carbohydrates, and even of proteids.

Philadelphia Medical Journal, April 6, 1901.

The Prophylaxis of Venereal Diseases. Medical Aspects of the Social Evil in New York. By Dr. Prince A. Morrow.—The author favors a campaign of education extended to the high schools and colleges for young men. The public should be educated to a recognition of the fact that the prostitute is largely the product of her environment. Society should deal with her as an unfortunate, rather than as a criminal.

On Certain Disorders of Sleep. By Dr. Charles A. Dana.—The author asserts that the greater part of these disorders arise from somewhat similar causes, viz., neurasthenia, lithæmia, arterial sclerosis, and cardiac weakness, and a few can be attributed to digestive disturb-

ances, or, perhaps, to abortive forms of epilepsy. The treatment of these symptoms is the treatment of the underlying condition. The bromides and hypnotics give relief, but these drugs are not often curative. The ordinary hypnotics are especially dangerous. More can be accomplished by heart and general tonics, by dealing with the lithæmia and arterial sclerosis, and thus promoting the patient's general health. Exercise, air, and peace of mind are the best hypnotics, and especially the removal of the fear of not sleeping. The safest medicinal agent is single small doses of bromide, persistently kept up.

General Metabolism in Diabetes Mellitus. By Dr. David L. Edsall.

A Preliminary Communication of a Study of the Brains of Two Distinguished Physicians, Father and Son. By Edward Anthony Spitzka.

Santiago as a Yellow Fever Centre. By Dr. L. C. Carr.

A Correlation of some Facts in the Propagation of Yellow Fever, with the Theory of its Conveyance by the Culex Fasciatus. By Dr. H. R. Carter.

Suprarenal Capsule—Its Use in Rhinological Operations. By Dr. Charles C. Royce.

Lancet, March 30, 1901.

The Topographical Anatomy of the Abdominal Viscera in Man. By Dr. C. Addison.—In the second of the Hunterian lectures upon this topic, the author discusses his subject under the following heads: Lateral displacements of the pylorus; movements of the stomach; the influence of the stomach upon the shape and position of the parts behind it; the duodenum; the small intestines; the peritonæum; and the lower end of the ileum.

Some Recent Developments in the Administration of Anæsthetics. By Dr. F. W. Hewitt.—In this article the author describes a modified Clover ether inhaler of his own. It has a very large bore and the face-piece is screwed into the ether reservoir, so that it cannot become unexpectedly detached. He also describes a modified Junker's inhaler and a "chloroform prop." This last is a metal wedge to be inserted between the teeth in place of a mouth gag. A bent metal tube for the transmission of chloroform vapor from a Junker's inhaler is affixed to the prop, the vapor thus escaping within the mouth and maintaining anæsthesia during throat and nose operations.

Cases of Injury to the Epiphyseal Line. By Dr. R. Bucknall.—The author reports six cases of injury to the epiphyseal line, in five of which cures were obtained by reduction and splinting. The sixth case was of long standing and the patient refused operation.

Note on the Treatment of Collapse of the Ala Nasi. By W. J. Walsham, F. R. C. S.

The Treatment of Sciatica, Arthritis Deformans, and Scleroderma by Superheated Dry Air (the Tallerman System). By Dr. Fr. Neumann.—In this article, which is a report from the Landesbad at Baden-Baden, the author warmly eulogizes the Tallerman system of hot-air treatment, and cites a large number of cases of arthritis deformans, chronic articular rheumatism, etc., which were greatly benefited by it.

Notes on a Case of Temporo-sphenoidal Abscess Following Middle-ear Suppuration; Operation; Recovery. By Dr. P. Jakins.

"Selenium Compounds as Factors in the Recent Beer-poisoning Epidemic." By Dr. F. W. Tunnicliffe and O. Rosenheim, F. C. S.

British Medical Journal, March 30, 1901.

Some Clinical Aspects of Chronic Bright's Disease. By Dr. A. G. Barrs.—The distinctions drawn by the pathologist between the different forms of chronic Bright's disease have little clinical value. The important point to determine is whether the condition is acute or chronic. The direct causative relation of acute to chronic nephritis is extremely doubtful. The author holds that acute nephritis has much the same definite march as acute pneumonia and ends in complete recovery or death. Alcohol and syphilis have little to do with acute nephritis, and even gout leads much more commonly to albuminuria than to glycosuria. The possibility of a bacterial origin for some of the chronic inflammatory destructions of the kidney cannot be denied. A diagnosis of chronic Bright's disease in the absence of albuminuria cannot safely be made; our ideas of such a condition are based largely upon post-mortem-room experience. While the presence or absence of albumin is the all-important point in the diagnosis, the quantitative estimation of albumin is of no importance whatever. Nor is the estimation of urea in cases where chronic nephritis is suspected, and albumin is absent, of any great value. Even a persistently low specific gravity of the urine is not a reliable indication. Cardiovascular changes are not so uniformly inevitable as is generally believed. Arteriosclerosis is a far more common cause of cardiac hypertrophy than chronic nephritis; the same is true as to cerebral hæmorrhage. Dieting has been greatly overdone in the treatment of chronic Bright's disease, and the distinctions drawn between the different meats are ridiculous. If the bowels are acting freely, the patient may live on such ordinary mixed diet, including meat, as he has an appetite for and can digest. The author has no great belief in the general treatment of Bright's disease by drugs, beyond the systematic use of purgatives to keep the bowels acting freely. As a rule, morphine or opium should not be given in renal disease; but in wakeful, painful, non-soporific uræmia with marked dyspnoea, morphine is of the greatest advantage and may be used with perfect safety.

On Generalized Infection in Gonorrhœa. By A. H. Ward, F. R. C. S.—The gonococcus, in its process of growth in the human body, produces an irritating toxine. This toxine is the direct cause of all the symptoms of the disease. In all cases it is absorbed into the system, where its presence causes systemic degenerations of varying degrees of severity. Gonorrhœa is thus a general toxæmic affection; but the microbes which form the toxine are generally localized on or around a mucous tract. The microbial invasion may extend to the organs communicating with the infected tract, or it may penetrate into the tissues, either by direct extension, as in the invasion of the peritonæum through the uterus and Fallopian tubes, or by a process of growth through the mucous membrane affected. Thence the infection may invade the cellular tissues, the lymphatics and glands, and the vascular system. This invasion is rendered possible by the action of the absorbed toxine upon the leucocytes, which is of a paralyzing nature, and prevents the encapsulation of the microbes by these cells. Having reached the circulation, the gonococci may invade the heart and endocardium, or may be carried to the peripheral capillaries. In these they become stranded and

grow, producing more toxine, which sets up local inflammations. The microbes invade the joints and are found in the synovial sacs, and also in the pleura and pericardium. They are probably present in the analogous inflammations of the tendons and periosteum. The invasion of the organism is favored by all too energetic measures directed to the local infection, since they depress the local powers of resistance, and, by abrading or lacerating the mucous surface, may directly open the door to the invasion. General treatment must vary according to the general conditions, and will differ when these are referred to toxæmia alone, or to toxæmia complicated by metastases. Local treatment is always required and should always be free from instrumental, mechanical, or chemical violence.

A Case of Congenital Hepatic Cirrhosis with Obliterative Cholangiitis (Congenital Obliteration of the Bile-ducts). By Dr. H. D. Rolleston and Dr. L. B. Hayne.—The authors report a case of this affection occurring in a male child, aged six months. The case is recorded, not only on account of its comparative rarity, but also in order to discuss the nature of the morbid process, which is done very completely. It seems reasonable to believe that the disease was primarily started by poisons derived from the mother, and conveyed to the liver of the foetus, and that a mixed cirrhosis and cholangiitis are thus set up.

The Treatment of Glycosuria and Diabetes Mellitus with Sodium Salicylate. By Dr. R. T. Williamson.—The author has used large doses of sodium salicylate (20 grains four times a day) in certain forms of diabetes mellitus, with the greatest benefit. In one case, in which there was a daily estimation of the amount of sugar excreted, the administration of sodium salicylate during several periods was in each instance followed by a marked decrease in the amount of sugar, until, finally, the urine became entirely sugar-free and remained so. Nineteen other cases are cited in which sodium salicylate was given. It is not a specific for diabetes; in the severe cases it does not usually produce any marked diminution of the sugar excretion, but the patients, as a rule, express themselves as feeling better while taking it. The drug should be carefully watched and should not be given if serious complications are present.

An Easy Operation for Congenital Ptosis. By Dr. F. Fergus.

Note on the Peculiar Nystagmus of Spasmus Nutans in Infants. By Dr. J. Thomson.—In most cases of head-shaking, or spasmus nutans, in young children there is nystagmus, which differs in some particulars from all other forms of nystagmus. Ordinary horizontal nystagmus is conjugate in character, the axes of the eyes remaining parallel. But the nystagmus of spasmus nutans is convergent, the eyes inclining alternately toward and away from each other. In the rotatory form the movements are those of circumduction rather than of pure rotation. The nystagmus is often unilateral, vertical, or rotatory in spasmus nutans; in the ordinary form it is almost invariably horizontal. These irregular, incoordinated movements are in agreement with and confirm the view that spasmus nutans is at bottom a co-ordination neurosis.

A Case of Tetanus Neonatorum Successfully Treated with Antitetanus Serum. By Dr. J. McCaw.

A Note on the Knee-jerk in Chorea. By Dr. W. Gordon.—The author calls attention to a peculiar modification of the knee-jerk very common in chorea. With

the patient recumbent, if one raises the knee, allowing the heels to rest on the couch, making sure that all the muscles of the limbs are relaxed for the time being, and if one then tests the knee-jerk in the usual way, the foot is found to rise more or less smartly, but instead of falling back immediately, it remains suspended for a variable time—hung up, as it were—and then slowly sinks back to its initial position. The author has never found this peculiar knee-jerk except in chorea, where it is common, and cites a case where its presence confirmed an otherwise very doubtful diagnosis.

Notes of a Case of Congenital Hypertrophy with Stenosis of the Pylorus. By H. Blackadder, M. B.

Lyon médical, March 10, 1901.

Severe Forms of Nervous Aerophagia.—M. L. Bouveret narrates a number of cases of this form of nervous disease which he was the first to describe. He says it is not a clinical curiosity, but may be the precursor of very grave nervous phenomena, such as excessive vomiting and vasomotor crises of severe degree. It appears most frequently after eating, the pathological irritation easily following the physiological in the centre for deglutition. Discipline of the patient is effective, sometimes, in causing a diminution of the swallowing of air. After eating, he is instructed to remain quiet and to assume the horizontal position. If he cannot voluntarily cease the deglutition of air, a small gag may be placed between the teeth, the stretching of the jaws arresting the pathological movements. Bromide medication is useful, and this may be combined with the general treatment of hysteria and neurasthenia.

Diacetic Ether of Morphine (Heroine) for Pain. By M. Jean Artaud. (*Continued article.*)

Indurated Erythema and Tuberculosis.—M. Carle reports a case in which a nodular erythema in a scrofulous woman, forty-nine years of age, proved to be tuberculous on microscopic examination. He emphasizes the deep induration of the nodule and its indolent character, its characteristic situation on the antero-external portion of the leg, and its concomitance with the scrofulous lesions, and its probable identity in origin with them. While inoculation experiments have not been very conclusive, nodular erythemata most often appear in persons with a tuberculous ancestry, and the histological examination frequently shows the presence of giant-cells with epithelioid characteristics. Treatment is long and must be general and local.

Cervico-facial Actinomycosis.—M. André Antipas reports such a case.

March 17, 1901.

Phototherapeutic Apparatus without Condenser for the Application of Finsen's Method. By M. Lortet and M. Genoud.

Heroine for Pain.—M. Artaud says that from his observations and those of others, there seems to be no doubt of the sedative and analgetic action of heroine administered subcutaneously. In all the patients pain disappeared in fifteen minutes. For the most part, the injection was not accompanied by any phenomena of disagreeable character, but occasionally slight nervous disturbances were noted. The sedative action of the drug lasted as long as that of morphine, while at no time were any secretory disturbances observed as is usually the case with morphine.

Presse médicale, March 13, 16, and 20, 1901.

Latent Nephritis in Saturnism. By M. Debove.

Chronic Parenchymatous Nephritis in Tuberculosis.

—M. L. Landouzy and M. Léon Bernard say that nephritis is not a disease entity; it is a function of disease, an anatomico-clinical reaction of the kidneys to the toxins of disease. The present study of the authors relates to but one of the renal reactions to tuberculous intoxication, the classical chronic parenchymatous nephritis. In some cases this is but a mask of the tuberculous process going on somewhere in the body, but which defies detection; in other cases it accompanies manifest tuberculous disease.

Semeiology of the Nervous System. By M. Jules Soury.

Gazette hebdomadaire de médecine et de chirurgie, March 14 and 17, 1901.

Radical Cure of Hernia. By M. E. Damas.

Bloodless Reduction of Congenital Dislocation of the Hip.—M. Hagopopf says that while he does not believe it possible to reduce the head of the femur into its acetabulum, it is possible—especially up to six years of age, to hold it in place by suitably constructed immobilizing apparatus. In this way, by watching the gait carefully, much can be accomplished during the active years of development.

Severe Forms of Nervous Aerophagia. By M. L. Bouveret. (See abstract from *Lyon médical*, March 10, 1901.)

March 21, 1901.

Hæmorrhage in Simple Acholuric Icterus.—M. Gilbert and M. Lereboullet have studied the hæmorrhages occurring in icterus with acholuria, and are convinced that the cholæmia is the basal cause of the bleeding, the presence of the bile in the blood, together with some accidental or physiological cause, leading to vascular rupture and bleeding.

Journal des praticiens, March 9, 1901.

Biological Mineralogy. By M. J. Gaube.

Tetranitrate of Erythrol (Tetranitrol).—M. Huchard recommends the use of this drug to combat heightened arterial tension and to strengthen the cardiac beat in myocarditis and other causes of weakened heart action.

Progrès médical, March 9, 1901.

Ovarian Opothrapy.—M. Lucien Picqué, in stating that the nervous symptoms following ovariectomy are almost identical with those of neurasthenia and some forms of hysteria, showing that the latter are due to ovarian insufficiency, urges the use of ovarian extract, saying that the good effects of this method of treatment last over many months, if a cure is not effected.

March 16, 1901.

Medico-legal View of Visual Strength.—M. Alphonse Péchin says that vision varies widely within normal limits. When one is called upon to give an opinion as to damages sustained when the claim of impaired vision is made due to accident, it is necessary to know or to ascertain the state of vision previous to the injury, in order that no injustice may be done to either side.

Wiener klinische Rundschau, March 17, 1901.

Contributions to Renal Surgery.—Dr. Joseph Preindlsberger, in a continued article, narrates several

cases of surgery upon the kidney, one of them in a case of echinococcus disease.

Pyloric Spasm in Children. By Dr. A. Köppen. (*Continued.*)

Toxicity of Expired Air. By Dr. Emanuel Formanek. (*Concluded.*)

Centralblatt für innere Medizin, March 16, 1901.

Reflex Excitation of the Pulse.—Dr. M. Heitler says that the pulse may be influenced reflexly by irritation of different parts of the body. If the liver is percussed, an increased rapidity and volume of the pulse may be noted, but it may be necessary to resort to the measure two or three times before the pulse is influenced. Next in point of ability to excite the pulse is the sternum, then the skin, the bones, and the muscles. Passive motions of the joints have less effect. In a case of deep coma with almost imperceptible pulse, the pulse improved after vibration of the liver, although percussion of the sternum had no effect. The skin may be thus employed by rubbing or stroking with the finger-nail. Its susceptibility is increased by placing hot or cold water over it after the rubbing.

Centralblatt für Gynäkologie, March 23, 1901.

Extra-uterine Pregnancy.—Professor Albert Sippel says that it can now be positively stated that, in tubal pregnancy, the ovum does not produce a decidual reaction in the tube, but an epithelial reaction, as has been shown by Peters. The epithelium of the tube responds first to the irritation of the impregnated ovule, it becomes hyperplastic, then atrophies, and the ovum sinks down into the epithelial lining of the tube. The epithelium of the tube, the author reminds us, is identical with that of the uterine cavity.

Temporary Ventrofixation.—Dr. H. Rose reports the case of a woman, twenty-five years of age, on whom he performed a laparotomy three days after the rupture of a tubal pregnancy. The uterus was retroverted, and, as the abdomen and Douglas's cul-de-sac were filled with blood, it was feared that the uterus might form permanent adhesions were it not elevated. So a temporary ventrofixation was performed, the uterus being united to the abdominal wall with catgut.

Riforma medica, February 20, 1901.

Allotropic Iodine and Immunization. By Dr. G. Levi.—Allotropic iodine, which has been obtained by the author from metallic iodine, differs in many respects from the latter as regards chemical properties. It has no odor, it is tasteless, non-irritating, and non-toxic, but is very strongly antiseptic. It does not give the characteristic reaction with starch, is not decolorized by ammonia, and does not attack metals. With alkaloids, it reacts in the same way as Gram's solution. It is rapidly absorbed by the tissues and penetrates them without leaving any traces. It is soluble in water, alcohol, ether, etc.

While immunization by means of bacterial antitoxines has reached a high level within recent years, but few attempts have been successful in the way of immunization (*i. e.*, of increasing the resistance of the body against disease) by means of chemical substances of known composition. Calmette has recently demonstrated that rabbits may be immunized against snake poison by means of injections of chemical substances like sodium chloride, calcium chloride, etc., and also that injections of these chemicals have proved curative in rabbits which

had been bitten by snakes from thirty to fifty minutes before the injection. Wiener showed, in a recent article, that the administration of arsenic and of creosote so modified the serum of rabbits, dogs, and other animals that the injection of serum taken from these animals during the treatment immunized other animals against various infections. It is known that iodine is one of the most important antagonists of bacterial activity, as is shown by the action of the thyreoid gland in the body. Hence, it is probable, *a priori*, that iodine is well suited for immunization of animals against infection. The author has attempted to demonstrate the truth of this supposition by a series of experiments. He injected a solution of allotropic iodine into a horse, and showed that, while cultures of the *Bacillus pyocyaneus* grew well on the serum of this animal before it had received the iodine, his serum proved to be absolutely germicidal after the treatment with the allotropic form of the drug. No traces of iodine were found in the blood of this animal, thus showing that the bactericidal action of the serum was not due to the iodine contained therein. The effect was due to a modification of the serum in such a way as to render it antitoxic.

February 21, 1901.

Experiments Concerning Hæmostasis in the Liver.

By Dr. Luigi Baldassari.—Numerous methods of arresting hæmorrhage from the hepatic tissue have been tried in connection with certain surgical operations which are from time to time performed on the liver, but until now with little success. The author has conducted experiments with a class of substances which may be used for the purpose of tamponing the hepatic wound, and which may be left there to become absorbed. Thus, it has been suggested that fibrin, gelatin, or small pieces of sponge be used for this purpose. Fibrin requires very careful preparation in order to render it perfectly sterile, and it does not adhere firmly to the liver; gelatin is a good hæmostatic, but does not adhere firmly enough to the subjacent tissues and favors the development of bacteria; sponge offers a nucleus for the development of new tissue, and is not absorbable. The author has conducted a series of experiments with decalcified bone as a hæmostatic. This substance is easily disinfected or rendered sterile; it is sufficiently solid for fixation by sutures, either in the form of a wedge introduced between the edges of wound, or in the shape of a plate placed over a bleeding surface. It is porous, and thus offers support for the formation of new tissue and is slowly absorbed.

Gazzetta degli ospedali e delle cliniche, January 20, 1901.

A Discussion Concerning the Diagnosis of a Case of Cachexia with Abdominal Symptoms. A Clinical Lecture. By Dr. E. Maragliano.

The Action of Iodocol and its Therapeutic Value.

By Dr. Giuseppe Cattani.—Iodocol is a combination of guaiacol and iodine, and as such it is said to modify the trophic processes by improving and stimulating organic metabolism, and at the same time to arrest inflammation. It is prepared by adding a solution of iodine and sodium iodide to a solution of sodium guaiacolate, in the proportion corresponding to the formula of moniodoguaiacol. A dark-red precipitate is obtained, which is washed and dried. The resulting dark-red powder is insoluble in water and imperfectly soluble in alcohol and ether. The insoluble portion contains 25.51 per cent. of iodine, or, in other words, one part of iodine to three of guaiacol. The soluble portion contains 45.46 per cent. of iodine. The ordinary dose is from 30 to 40 centigrammes ($4\frac{1}{2}$ to

6 grains). It may be combined with vegetable powders, such as gentian and quebracho. Gastric disturbances are very rarely observed, and no untoward symptoms of any kind on the part of the heart or the respiration are noted. The phenomena termed iodism follow the use of iodocol only very exceptionally, and then only in a very mild form. The remedy may be given for months without producing any symptoms of intolerance. Iodocol may be used with advantage in affections of the respiratory organs, as well as in tuberculosis of the intestines.

A Solitary Adenoma in a Cirrhotic Liver. By Dr. Giuseppe Jona.

The Prophylaxis of Rickets.

By Dr. Giacomo Silva.—The author discusses the various theories that have been proposed as explanations of the pathogenesis of rickets, and concludes that the dietetic theory has more foundation in fact than any of the others, including the toxic, the infectious, the nervous, and the syphilitic theories. The only preventive measure is proper feeding by modified milk in default of mother's milk. An analysis of the cases of rickets that were treated in his hospital during the last five years showed that the total number of rhachitic children was 577, of whom 270 were boys and 307 were girls. Of these children, 246 had been fed on mother's milk until the fourth or fifth month; 63 had received cow's milk from birth, or during the first few months of life; 159 had been fed on breast milk by wet-nurses, and 109 had not received milk in any form. The majority of these children, therefore, received breast milk; but this fact must not be regarded as contradictory to the dietetic theory of rickets, for the milk of the mothers of the poorer classes is almost always deficient in quality and quantity, and the children generally receive at an early age other food besides breast milk. An investigation into each case showed that not one of the 577 children had received a rational diet. The problem of milk modification is especially difficult of solution among the poor, inasmuch as the more elaborate and expensive processes that have been recently recommended are not available in such cases.

Pithecoïd Characteristics in a Demented Subject.

By Dr. Riccardo Albericci.—The author had occasion to observe the actions of anthropoid apes, and became convinced that their behavior very often resembled that of certain demented persons. He describes a case of senile dementia in a woman aged sixty years. There was something distinctly simian in the expression of this person's face, and the woman's movements and general manner were very markedly ape-like. Her spine presented the diminished curvature of the primates, and the shape of her thorax approached that of the foetus or the anthropomorphous simians. The predominance of the face over the cranium was so marked that it approached the limit of possibility, so far as a human being is concerned. The lower jaw was excessively heavy, and the prognathism was very marked.

Chirurgia, January, 1901.

The Experimental Method in Anatomy. By Dr. N. I. Napalkoff.—The author describes the value of experimental methods in the study of normal human anatomy. Dissection alone is not sufficient for the study of some structures, and experiments on living persons, as well as on dead bodies, are necessary for the study of the mechanism of joints, the effect of ligation of vessels, etc.

Cauterization by Means of Solar Rays and Hot Air.

By Dr. N. N. Michailoff.—The use of red-hot iron, now supplanted almost entirely by the apparatus of Pacque-

lin, has the marked disadvantage that it is very difficult to regulate the amount of heat applied, and therefore the boundaries of cauterization. The result is that unsightly scars are often obtained. In the latter part of the 'seventies, Barnes, an American physician, proposed the use of direct solar rays for the purpose of cauterizing tissues. In 1894, Thayer strongly advocated the adoption of Barnes's method. The disadvantage of this method is, unfortunately, that it cannot be employed in cloudy weather. The only apparatus necessary is a strong biconvex lens.

Schwabe, of St. Petersburg, has recently constructed an apparatus for the application of hot air in cauterization. It is practically identical with Pacquelin's cauterizer, except that the platinum end is spherical and terminates in a thin, open beak. A rubber tube is attached at the side of the platinum tip, and leads to the tube connecting the rubber bulb with the tip; in other words, this second rubber tube, which runs parallel to the tube of the original apparatus, does not go through the bottle of benzine as the latter does, but connects the tip directly with the air bulb. When the bulb is compressed a part of the air goes through the benzine and renders the tip incandescent, while the rest of the air passes along the second tube directly into the tip, where it is heated to a degree corresponding to the heat of the tip (probably about 300° C.), and escapes in a thin stream from the beak of the platinum tip. The author has used this apparatus in a number of cases, and has also employed direct solar rays for the purpose of cauterizing tissues. He has found that these methods are superior to the ordinary thermocautery and actual cautery, because they destroy the vitality of tissues by simply drying them up, without charring or breaking them down mechanically. Therefore, it is possible by these new methods to extend the cauterization to the surrounding healthy tissues when necessary (so as to destroy any traces of new growth, etc.), without producing destructive alterations in the healthy parts. While using the lens, it is best to wear smoked glasses, as the focused rays are too bright for the unprotected eye of the operator. The rays may be accurately focused first on a piece of cardboard which is placed over the tissue to be cauterized, and then removed. At first the spot becomes white, then light-gray, and finally it begins to char and steam. The light-gray stage is sufficient for tissues that are not very thick, as it indicates complete desiccation, and a few seconds are usually enough to secure this. The author has used this method in a great variety of cases, including lupus, naevi, warts, etc., and believes it to be ideal in every respect. The effect of Schwabe's apparatus is very similar to that of the lens.

The Diagnosis and Treatment of Gall-stones. By Dr. P. I. Diakonoff.—The author reports the history of five patients who had been operated upon for gall-stones. In addition, he gives the statistics of thirty-one cases of gall-stone that had been operated upon by Russian surgeons. Of the total number (thirty-six), five were men, thirty were women, and in one case the sex was not recorded. Ten patients were between the ages of twenty and twenty-nine years, seven between thirty and thirty-nine years, ten between forty and forty-nine years, four between fifty and fifty-nine years, three between sixty and seventy years, and in two cases the age was not recorded. Cholecystotomy was performed in seventeen cases, with three deaths; cholecystectomy in nine cases, with three deaths; in two cases choledocotomy was performed, and, in two, the operation did not correspond to any of these

types, but consisted in the removal of stones from the gall-bladder. In nearly all cases the cause of death could not be connected with operation itself. The reason why so few patients with gall-stones are operated on is that they reach the surgeon only through the medium of the physician, and, therefore, the number of cases of gall-stone operated upon ultimately depends upon the view of the matter taken by the general practitioner. The fact that gall-stones are found in the gall-bladder of patients in whom laparotomy has been performed for some other cause, and that the same condition is found in dead bodies of persons who have never suffered from any symptoms of gall-stones, show that cholelithiasis may exist without any clinical symptoms. The chief trouble as regards the prognosis of operations is that the cases reach the surgeon too late in most instances. In speaking of the indications for operative intervention, the author says that every case of gall-stones should be considered as one in which a surgical operation is necessary, because the development of gall-stones may be followed by grave consequences. The only absolute contraindication to operation is a high degree of cachexia, while the uncertainty in the diagnosis or an early stage of the disease, when medicinal treatment is of some value, may be considered as relative contraindications. The operation to be selected depends, of course, upon the situation of the stone and the extent of the secondary lesions. A recurrence of the trouble may be expected even after the most careful removal of all the stones.

Journal Akouscherstva i Gienskich Boliesney, December, 1900. (Journal of Obstetrics and Diseases of Women, St. Petersburg.)

The Suturing of the Laparotomy Wound and the Drainage of the Peritoneal Cavity after Laparotomy. By Dr. A. P. Goubareff.—It is wrong to judge the value of any particular method of suturing the abdominal wound by studying the statistics of hernias that have occurred after the use of the method in question. Regard must be paid to the question of aftertreatment; for, with proper aftertreatment, almost any method will succeed in securing a firm cicatrix and preventing hernia. Thus, Kraske has succeeded in obtaining a perfect result without any sutures whatever, simply by persistent and careful aftertreatment. Even an incision made transversely across the abdomen over the symphysis will heal without any danger of hernia if properly treated by bandages and elastic belts after the operation. On the other hand, triple tiers of sutures are without avail against hernia if the aftertreatment is neglected. The author has seen many cases in which a simple interrupted suture, like that used by Sir Spencer Wells, sufficed to secure the edges of the wound so well that a perfectly sound scar resulted. It is wrong to depend on the sutures, no matter how complicated and how strong, for the union of the edges. Without the healing process which Nature provides there can be no good scar. The office of the sutures is simply to bring the surfaces together to enable Nature to heal the wound, and not to secure the patient against possible interference with healing caused by vomiting, coughing, or straining. A sufficient approximation of the edges for the purposes of healing is, in fact, secured by a simple bandage, and there is no reason why sutures should be employed. If this point of view is taken, the question as to suturing the laparotomy wound becomes identical with the question as to the necessity of suturing a wound in any other part of the body.

In order to obtain a suture fulfilling all requirements, one may use a deep and a superficial continuous suture

and two or three interrupted sutures serving to prevent accumulation of secretions in the bottom of the wound. The first of these sutures should include the peritonæum and the tendons of the flat muscles of the abdomen. Two or three deep interrupted sutures will suffice to bring together the adipose layers of the abdominal wall if these are abundant, and, finally, a "subcutaneous" suture, as described by Kelly, may be used for the skin. Both continuous sutures should be of deer tendon. After the sutures have been placed, the wound should be wiped with peroxide of hydrogen, and a roll of sterile gauze laid upon it, the ends of the deep interrupted silkworm-gut sutures being tied over this gauze. Perfect quiet must be maintained and, if vomiting appears, a bandage or an elastic belt must be provided. As regards drainage, the author sums up the modern view of the subject with the words: "When in doubt don't drain." Drainage is required in cases in which the hæmorrhage is not completely arrested, when the peritonæum is supposed to be infected, and after the operation, when there are symptoms of internal hæmorrhage or of exudation of fluid in the peritonæum.

The Pathogenesis of Eclampsia as Shown by the Statistics of the Obstetric Clinic and Polyclinic in Kieff. By Dr. D. Abuladze.—During the last sixteen years there have been 45 cases of eclampsia among 2,926 women who had been admitted to this clinic; in other words, 1.5 per cent., or 1:65. The author gives a number of statistical tables, and concludes as follows: The infectious nature of eclampsia, in the sense accepted by Stroganoff, is more than doubtful. [Stroganoff considers eclampsia as an infectious condition and the albuminuria as a secondary phenomenon.] The author found albuminuria in 50 per cent. of his cases, and the cessation of albuminuria coincided with recovery from eclampsia. He does not affirm, however, that eclampsia is due to a renal affection.

The Operation of Suturing the Ureters into the Rectum. By Dr. S. A. Alexandroff.—The author believes that this operation should be more frequently employed than it is at present. When a ureter is wounded it is easier and less dangerous to sew it into the rectum than to resort to nephrectomy or to ligation of the ureter so as to exclude the kidney from the organism. In tuberculosis or malignant tumors of the bladder this operation is also indicated, and in large fistulæ of the bladder, susceptible of operation, it may take the place of epistocleisis. In some cases it may serve in place of colpocleisis, which does not guarantee the patient against ascending renal infection, but may give rise to the formation of stones in the bladder, and at the same time limits the sexual activity of the patient. Of course, the operation of sewing the ureters into the rectum will always be the last resort in fistulæ of the bladder in view of the progress made in the technique of operations for vesicovaginal fistulæ at the present time.

A Case of Vaginal Hysterectomy Immediately after Labor on Account of Carcinoma of the Vaginal Portion. By Dr. I. A. Strauch.—According to Sarwey, only one case of labor in a woman with carcinoma of the uterus could be found among 2,000 labor histories. The patient was a quintipara, aged thirty-five years, and the carcinoma developed during the last pregnancy on the soil of a lacerated cervix. The author's conclusions are as follows: The induction of premature labor or abortion is not permissible in pregnant uteri affected with carcinoma. Before the eighth month, immediate complete extirpation is indicated, without regard to the life of the

child, in cancers of the uterus susceptible of operation. Before the fourth month one can easily remove the cancer without removing the fœtus. After the fourth month, the uterus must first be emptied. If the child is viable, a vaginal or abdominal Cæsarean section must be performed, and the uterus must be immediately removed. In carcinomas insusceptible of operation, one must only regard the life of the fœtus, as the mother is doomed. The end of pregnancy must therefore be awaited, and the child then extracted in a way best suited to its preservation. If the vaginal route is not practicable, abdominal Cæsarean section must be resorted to. Wherever possible, the vaginal method, both for extraction and for hysterectomy immediately following, should be preferred.

A Case of Cæsarean Section with Relative Indications. By Dr. V. Stolypinsky.—The patient had not borne a child to term before, and, on examination, presented a very marked general narrowing of the pelvis, and it was decided, upon consultation with Professor Fenomenoff, to perform Cæsarean section at the proper time. The head presented, and the cervix admitted two fingers when the operation was performed. Both Falloppian tubes were ligated and cut, in order to comply with the wishes of the patient, who desired to be freed from a possibility of future pregnancies. After the uterus had been opened the hæmorrhage from the uterine arteries was arrested by compression exercised by an assistant. No elastic compression of the lower segment was used.

Vratch, February 17, 1901 (March 1, 1901, New Style).

The Surgical Treatment of Ascites in Atrophic Cirrhosis of the Liver. By Dr. N. M. Benissovitch.—The author reports two cases in which he performed Talma's operation for ascites due to atrophic cirrhosis of the liver. Talma, of Utrecht, proposed, in 1889, an operation the purpose of which was to relieve the congestion of the portal system by directing the blood into other and new channels. He proposed that the great omentum should be sutured to the anterior abdominal wall in order to stimulate adhesions between the sutured surfaces, and thus to favor the formation of veins connecting the radicles of the portal system in the omentum and the veins of the anterior abdominal wall. In this manner the portal congestion would be relieved. Talma did not succeed in applying his idea in human beings, but Morrison, Eiselsberg, and others performed this operation with good results. In the author's first case the ascites returned after the operation, but very slowly, and the general condition improved considerably. In the second case, the patient lived very comfortably for a fortnight after the operation, but for some reason or other he was seized with an attack of cardiac weakness and died on the fifteenth day. There was no autopsy, and therefore it was impossible to state the cause of death, but the author thinks that the operation rather prolonged the patient's life. The theoretical foundation for this operation was first laid down by Claude Bernard, who showed that animals bore gradual occlusion of the portal vein perfectly well, provided a collateral circulation was secured. Tillmann and Kouznetzoff have also contributed experimental work on this subject.

Medical Attendance for the Operatives in some Factories of the Vladimir Province in the Years 1896-1898. By Dr. M. S. Kamneff.

Concerning Diseases of the Cerebellum. By Dr. P. I. Schatiloff. (*Continued.*)

Proceedings of Societies.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of March 5, 1901.

The President, Dr. JOSEPH COLLINS, in the Chair.

Muscular Dystrophy.—The PRESIDENT presented for diagnosis and discussion a boy of ten years, who presented a complex of symptoms which could not easily be placed under any one designation. He was one of twelve children, seven of whom had had in infancy marasmus or gastro-intestinal disorders. The present ailment had begun about nine months ago, at which time the boy had begun to "hop." He complained of pain in the great toe of the left side, and also of pain in the præcordial region. He had then been taken to the Mount Sinai Hospital, and while he was there it had been noted that there was some stiffness or weakness in the lower limbs on walking. This impairment of motion has steadily increased, so that at the present time he was practically unable to walk more than a few steps. According to the history, there had been early in the disease great difficulty in beginning the act of micturition. At present there were no symptoms referable to the bowels or bladder. He had a peculiar waddling gait, and when he was standing there was a typical flat-foot. There was a peculiar knocking together of the thighs. The spasticity of the gait had been found, on closer examination, to be more apparent than real. There was a marked ankle clonus. There were no sensory disturbances. The boy got up from the recumbent posture as children did in the early stages of progressive muscular dystrophy. These symptoms, the speaker said, seemed to point distinctly to a lesion in the spinal cord in the crossed pyramidal tracts.

Dr. B. SACHS said that he had been much interested in this boy at the time he had been in the hospital. The combination of the waddling gait, so characteristic of the dystrophy, with an increase in the reflexes seemed to be especially unusual. When the boy was stripped, it seemed to him very evident that he had progressive muscular atrophy of the Landouzy type. In addition to this, he thought there was a subacute myelitis, possibly of traumatic origin. There could be no question that the calves were hypertrophied. This diagnosis had been arrived at only after careful observation for a period of several weeks. The frequent falls which children had would easily explain the occurrence of a subacute myelitis. The spasticity had been more marked nine weeks ago.

Dr. GRÈME M. HAMMOND said that from the cursory examination that he had made he felt inclined to agree with Dr. Sachs.

Dr. WILLIAM M. LESZYNSKY said that it seemed to him to be a very atypical case. He had seen quite a number of patients in whom there had been complete spasticity, and yet the ankle clonus had been very marked.

Dr. JOSEPH FRAENKEL said that the most prominent symptoms were those of disease of the lateral and posterior columns. At first sight the gait was that of ataxic paraplegia. On the supposition that the myelitis was the later disease, one would expect less evidence of the second. The evidences of pseudohypertrophy were certainly quite trifling, while the disease of the cord was very marked. He inclined to the diagnosis of subacute multiple sclerosis of a paraplegic type.

Dr. J. ARTHUR BOOTH said that there was certainly a greater deposit of soft tissue in the left than in the

right calf. He accepted the views expressed by Dr. Sachs.

The PRESIDENT thought it was safe to assume that the boy had a dystrophy, but not that there was a subacute myelitis. No one could say whether the changes in the spinal cord which accompanied the dystrophies were of such nature that double ankle clonus and double knee-jerk might not develop. It was certainly a form of dystrophy which did not conform strictly to the description of any usually given. If there was an implication of the cord, it was confined entirely to the crossed pyramidal tracts. He would not be willing to admit that there were any changes in the spinal cord except secondary ones.

Progressive Muscular Dystrophies, with a Report of a Post-mortem Examination.—Dr. SACHS and Dr. HARLOW BROOKS presented this paper. The authors stated that it could not be denied that there was a sufficient distinction between the amyotrophies and the dystrophies. In former years much stress had been laid on the muscular structure. Hypertrophied fibres were found in abundance in dystrophies, whereas in the amyotrophies these fibres were not found. But later it had been shown that the hypertrophied fibres were found in other diseases than dystrophies. It was also a question whether the gray matter of the cord was affected in the primary dystrophies. The case to be reported was one of progressive muscular dystrophy of fifteen years' duration, yet the structural changes, as demonstrated by the latest methods of staining, were very slight. The patient had been admitted into the Montefiore Home eleven years ago, at the age of twelve years. Early in his life the parents had noticed peculiar movements of the head and eyes. He had been in good health up to about the age of ten years, when he had fallen and broken his leg. At the age of twelve years, after an attack of typhoid fever, it had been noted that the calves were decidedly hypertrophied. The head was enlarged and exhibited certain movements. There was a marked atrophy of all the muscles of the shoulder girdle, arm, and forearm. The deep spinal muscles were intensely atrophied. The thigh muscles were atrophied. The case became an extreme illustration of a progressive muscular disease of the pseudohypertrophic type. The lad's intelligence was fair. Dr. Brooks said that at the autopsy the organs were normal, with the exception of an acute pneumonia and a slight myocarditis. There were no gross lesions of the brain or spinal cord. No lesion of the smooth voluntary muscular tissue could be found anywhere in the body. The psoas muscle showed extensive fibrosis. The muscles of the back all showed extensive fibroid replacement, and in places there was replacement by yellow fat. The trapezii were very extensively invaded. The most extreme changes were in the muscles of the calves, where normal muscular tissue was lost. The autopsy had been done twenty-four hours after death, and at that time there had been no evidence of post-mortem decomposition. On microscopical examination, the muscles showed extensive replacement with areolar tissue of the adult type. In the calf, occasional remnants of voluntary muscle were found. Most of the fibres of the psoas muscles were either larger or smaller than normal. The coarse striæ could usually be made out. The changes in the other voluntary muscles were of the same character, though varying in extent. In the occipital muscles the amount of connective-tissue hyperplasia was less, but nuclear proliferation was prominent. Examination of various portions of the smooth muscles failed to show degeneration or hyperplasia of the connective tissue form-

ing their framework. The heart muscle showed much less connective-tissue increase than had been expected from the gross examination. The cardiac muscle was in a very natural condition, there being no atrophy, no abnormal pigmentation, and no abnormal nuclear activity. The blood-vessels in the various tissues showed uniformly an increase in the connective tissue. No evidences of new vessel formation were found. Numerous peripheral nerves were examined, but no appreciable degeneration of fibres was discovered. Only a few of the spinal ganglia had been properly prepared for examination, but these few showed a shrinkage of the ganglion cells similar to that produced by fixing agents. The irregular perilymphatic spaces were, however, found filled in with proliferating capsular cells, apparently indicating that this was not an artifact, but a distinct pathological process. Apparently the connective tissue of the ganglia had been increased. The connective tissue throughout the entire cord was found to be increased. The blood-vessels of the cord were universally congested, but this was apparently of a hypostatic nature, due to the position of the patient before death. Nothing in the nature of a systemic degeneration of the fibres was found at any level. In the cervical region the ganglion cells in the anterior horn showed a slight nuclear eccentricity. The dendrites universally retained their power to respond to the stain. Occasionally the achromatic elements stained to a slight degree. Eccentricity of the nucleus was found more commonly in the dorsal cord than elsewhere. Lesions in the cells of the posterior horns were more infrequent than in the anterior horns. The most common lesion was a finely granular subdivision of the plaques, usually not involving the entire cytoplasm. A few of the lumbar cells showed an unusual amount of brown pigment collected about the nucleus. The chief lesions were: 1. Extensive atrophy, which affected apparently all the voluntary skeletal muscles and was confined to these muscles. 2. The production of areolar connective tissue and fat. 3. Slight general circumvascular hyperplasia. 4. Moderate interstitial myocarditis. 5. Extensive degenerative changes in a few of the posterior-root ganglia. 6. Rare changes in the cytoplasm of the ganglion cells of the spinal cord. The complete absence of the changes in the smooth muscles showed that the disease process was strictly localized in the voluntary muscular system. The authors did not look upon the connective-tissue increase as an essential feature of the pathological process, but as an example of a universal function of this tissue in taking the place of any tissue which had been removed. The circumvascular connective-tissue hyperplasia was very slight, and could not be considered as typical of the disease or as produced by it. Possibly the moderate myocarditis was associated with the connective-tissue hyperplasia of the blood-vessels. It did not seem to be in any way connected with the factors producing atrophy of the voluntary muscles. The changes in the posterior-root ganglia seemed to be of great significance, though it was not clear that they bore any direct relation to the changes in the voluntary muscles. These degenerations seemed to be secondary in their nature, and dependent upon death or disease of certain portions of the neurone. A process similar to this occurred after amputation. There were, therefore, no evidences of tract disease. The cytoplasmic degeneration of the ganglion cells in the cord were rare, and might represent the early stage of post-mortem change. Dr. Sachs said that these findings did not indicate that the cause was to be found in the gray matter of the cord.

The disease represented a primary affection of the muscular fibre. The occurrence of stigmata of degeneration in so many cases of this dystrophy would lead one to think that these should be broadly classified under family affections. The question arose as to whether these muscular dystrophies were essentially progressive, and the statement was made that in every case the possibility of great improvement by systematic exercise should always be kept in mind in the early stage. Two illustrative cases were briefly reported which had been followed for many years.

Dr. C. L. DANA said that, so far as the dystrophies were concerned which were not strictly of the so-called pseudohypertrophic type, but rather of the arm and leg types, it seemed to be a well-known fact that many of them ceased to progress and the patients lived for many years in comparative comfort. He had personal knowledge of two families in which there were six or seven persons, going through three degenerations, who were afflicted with the leg or arm type of dystrophy. Some had lived to old age with only an inability to use the upper arm or perhaps the thigh muscles. One of these persons had been seen at many clinics in this city when thirty-nine years of age. The atrophies had begun at the age of nineteen, and had reached their height at about the age of twenty-nine. His weight had been reduced to eighty-eight pounds. A fairly hopeful prognosis could be given in this class of cases, especially when the atrophies did not begin very early in life. In his experience with pseudomuscular hypertrophy there had been only one case in which the disease had been really checked. This person was a lady of twenty-three, in whom the trouble had begun at the age of eighteen. She had presented all the typical symptoms of pseudohypertrophy of late development. He had put her upon systematic exercises, and as a result not only had the disease ceased to progress, but she had absolutely improved. In another case which had been faithfully treated by exercise and massage for four years there had been continued progress. Dr. Dana would like to have Dr. Brooks explain why there should be so much fibrosis in these cases. It might be that in the death of the muscle fibre an irritant poison was formed, and that this gave rise to the increased proliferation. There was a striking difference, clinically, between a typical spinal atrophy and an ordinary dystrophy, and he believed these diseases were very different in their origin also. The hereditary cases were of a type which was quite distinct from that of the acquired forms.

Dr. A. WIENER said that about six years ago he had presented to the society a patient who was very much crippled in his muscular movements. In that case he had been so convinced that many muscular fibres were still intact that he had carefully trained the patient in exercises for six months. He had been again presented to the society at the end of that time, and the improvement had certainly been very marked—indeed, the day previous he had been able to ride forty miles on his bicycle. On the other hand, in the dystrophies occurring early in life, he did not believe much could be gained by exercise.

Dr. LESZYNSKY exhibited photographs of two patients whom he had had under his care for a number of years with pseudohypertrophy of the lower extremities and progressive muscular atrophy of the upper extremities. Both had died of some intercurrent disease at the age of twenty-five. Before he had seen them, both had received massage and careful training in physical exercise.

Book Notices.

Dr. HAMMOND said that he had recently made a post-mortem examination in a case of pseudohypertrophy with rather interesting findings. In the lumbar enlargement of the cord there had been found a distinct cavity extending for several inches. In the dorsal segment was a large gliomatous mass pressing upon the cord. This was apparently a lesion independent of the disease in question. He was in a position to agree entirely with Dr. Wiener as to the beneficial effect of exercise. He had tried systematic exercise in those affected early in life, and had not found the slightest benefit from carefully conducted exercises of this kind carried on for a considerable time.

Dr. B. ONUF said that the muscles which had to do the most work were the ones most affected; the muscles which must bear the weight of the body were the first ones to become affected. It was because of this fact that he had been led to try the effect of the opposite plan of treatment—*i. e.*, rest in bed. However, the result had been disappointing.

The PRESIDENT said that the post-mortem examination referred to by Dr. Hammond had been on a patient that had been under his own observation for over two years. This man was twenty-four years of age at the time of his death, and the disease had existed for fourteen years. Careful investigation into the family history had shown no similar case. Up to his eleventh year he had been free from all disease. For eleven years he had been unable to walk, and for eight years had been bed-ridden. Up to a short time before death he had retained the ability to move his fingers, though he could not move his arm, and his facial muscles continued to act well. It was a most typical case of progressive muscular dystrophy. Death had resulted from a tuberculous infection. The brain reported on by Dr. Sachs had been from a boy under his observation for six or seven years. Assiduous attention to calisthenic exercises had made him worse in proportion to the assiduity, and that, too, although he had had an excellent calisthenic teacher. This had been the speaker's experience in all other cases in which the disease had begun early in life. The changes described by Dr. Brooks as having taken place in the ganglion cells certainly opposed one's ideas of the relation of the neurone to disease. After five years' experience with the Nissl stain, he felt in a position to assert positively that nuclear eccentricity meant absolutely nothing.

Dr. SMITH ELY JELLIFFE said that he had heard nothing said by Dr. Brooks about the terminal end-plates of the motor nerves.

Dr. BROOKS replied that, after attempting to study end-plates, he had come to the conclusion that this could only be done with methylene-blue during life, and that he had been unable to do. He could not tell Dr. Dana why the connective tissue should grow up so much more in one place than in another. In the calves there had been an increase in volume, and in the pectoral muscles a decrease. It was not improbable that it was due to some inflammatory or toxæmic condition in these particular muscles, or possibly the muscle had been over-exercised. He agreed with the president about the uncertainty of the Nissl stain, and said that the findings described by him as having been observed in the ganglion cells were negative.

Dr. SACHS admitted that the findings reported in the paper certainly did tend to shock one's confidence in the neurone theory as a whole.

Hand Atlas of Human Anatomy. By WERNER SPALTEHOLZ, Extraordinary Professor of Anatomy in the University and Custodian of the Anatomical Museum at Leipsic, with the Advice of WILHELM HIS, Professor of Anatomy in the University of Leipsic. Translated from the Third German Edition by LEWELLYS F. BARKER, Professor of Anatomy in the University of Chicago. With a Preface by FRANKLIN P. MALL, Professor of Anatomy in the Johns Hopkins University at Baltimore. Volume I: Bones, Joints, Ligaments. Leipsic: S. Hirzel, 1900. London, Edinburgh, Oxford: Williams & Norgate. New York: G. E. Stechert.

GERMAN students in this country are familiar with Spalteholz's *Anatomy*, which is distinguished for its superb illustrations and its condensed but thorough text. Dr. Barker has done a good service in translating the work into English and thereby making it accessible to the English-reading public.

The first fasciculus of the work, dealing with the bones, joints, and ligaments, is now before us. The continental nomenclature—that is, the Latin phraseology—has been retained, and, while this will be greeted with cordial enthusiasm by those who desire a uniform use of terms in science, confusion has been avoided by placing the terms of the old nomenclature in brackets where it differs widely from the new. Special attention has been paid in the development of a dissection step by step, and to the topographical relations of the vessels and nerves.

A word as to the illustrations, which are far above any similar ones within our knowledge. Most of them are in half-tone, and many of them are colored for purposes of clearness. They represent actual dissections, and the excellent principle has been adopted of making the text secondary to them in order that the student may form his basic anatomical ideas from the dissection, and not from the printed text.

As a superb guide to the study of anatomy, we do not see how this work can be eclipsed; it is *facile princeps*.

Orthopædic Surgery. A Handbook. By CHARLES BELL KEETLEY, F. R. C. S., Surgeon to the West London Hospital, etc. Pp. xvii-539. London: Smith, Elder & Company, 1900. [Price, \$5.50.]

THIS work, as the author frankly states in his preface, is written as a presentation of his own views and observations, based on more than twenty years of surgical practice, and largely influenced by Lannelongue, von Miculiez, Busch, and Bouvier. As is usual in foreign orthopædic treatises, joint diseases are not included, but there are interesting sections on chondrodystrophia, osteitis deformans, and acromegaly, subjects often omitted.

The author is interesting and suggestive in the operative sections, though sometimes an enthusiastic rather than a safe guide. His enthusiasm, however, does not seem to extend to the section on non-operative treatment, in which the inquiring students will often be disappointed at the paucity of the material and the vagueness of statement on these topics, which, after all, comprise nine tenths or more of orthopædic practice as seen in this country. Surgical literature is freely quoted, but there is no bibliography. The author's style is vivacious, but the arrangement is sometimes defective, a fault

which is partly atoned for by a full analytical index at the head of each chapter.

Les Maladies qu'on soigne à Berck. Adénites, tumeurs, blanches, coxalgie, scoliose, mal de Pott, luxation congénitale, etc. Masson et Cie.

THE diseases treated at Berck-sur-mer, a small town on the French side of the English Channel, are mainly the peripheral and joint tuberculous affections, rhachitic troubles, and other deformities of children. Berck is only one of a considerable number of coast towns in France, Italy, and other European countries where hospitals and sanatoria for the treatment of such affections exist, and many European surgeons report an excellent effect upon rhachitic and tuberculous affections from a prolonged sojourn on the sea coast. Dr. L. Cabot is well known in connection with the method of forcible reduction of the deformity in Pott's disease, which was brought forward with considerable *frio* by French surgeons about five years ago; he is also the author of about fifty papers and addresses on the surgery of childhood. It is interesting to learn that Dr. Cabot, who states that he has himself excised eighty hips, has entirely given up excisions of joints, curetting, and even the incision of cold abscesses, relying solely upon hygiene, diet, sea air, and repeated aspirations and injections of antituberculous fluids, such as a solution of iodoform in ether, camphorated naphthol, and chloride of zinc, 1 to 50. He reports marvelously rapid and certain results from this method.

His position in regard to the use of force for the reduction of the deformity of Pott's disease is much more conservative than in his first writings, in which he advocated extreme force under chloroform anæsthesia in nearly all cases. He now uses gentle or moderate force, with or without anæsthesia, in selected cases only, and virtually rejects laminectomy.

Dr. Cabot uses the bloodless method almost exclusively in congenital hip luxations, which is also the present practice of Lorenz, who was a short time ago the great exponent of the cutting operation.

Some of the views advanced by the author differ widely from accepted practice, such as his advocacy of long periods of recumbency and his entire rejection of gymnastic exercises in lateral curvature, but the brochure is interesting as emphasizing the value of the marine treatment and as throwing some light on the present status of the surgery of deformities in France.

Golden Rules of Skin Practice. By DAVID WALSH, M. D. Edin., Hon. Physician to the Western Skin Hospital, London, W., etc. Golden Rule Series. No. VIII. Pp. 5 to 102. Bristol: John Wright & Company. London: Simpkin, Marshall, Hamilton, Kent, & Company, Ltd., 1900. [Price, 1s.]

THIS little volume contains a number of useful hints in the diagnosis, care, and treatment of persons suffering from cutaneous ailments. The "don't's" in the book are as numerous and as important as the positive directions. While we imagine that specialists will be familiar with most of the dicta, we believe that for the general practitioner the little book will prove useful.

Experimental Research into the Surgery of the Respiratory System. An Essay awarded the Nicholas Senn Prize by the American Medical Association for 1898. By GEORGE W. CRILE, A. M., M. D., Ph. D., Professor of Clinical Surgery, Medical Department, West-

ern Reserve University, Cleveland, etc. Second Edition. Pp. 5 to 114. Philadelphia: J. B. Lippincott Company, 1900.
